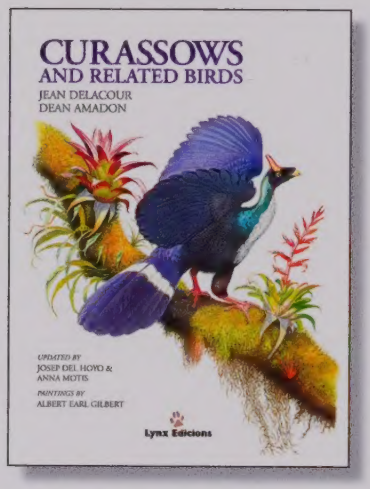
HANDBOOK OF THE BIRDS OF THE WORLD

Edited by
Josep del Hoyo
Andrew Elliott
David Christie

Volume 9

Cotingas
to
Pipits and
Wagtails



Lynx Edicions

BirdLife INTERNATIONAL

After the successful publication of
Threatened Birds of the World
in association with BirdLife International

Lynx Edicions is about to publish two other important works in association with world-renowned scientific institutions

Due Summer 2004

In association with the American Museum of Natural History

Due Autumn 2004

In association with the Smithsonian Institution

Jacket illustration by FRANCESC JUTGLAR
Andean Cock-of-the-rock (*Rupicola peruvianus*)
Ochre-breasted Pipit (*Anthus nattereri*)

HANDBOOK OF THE BIRDS OF THE WORLD

Authors of Volume 9

Dr P. Alström
Department of Systematic Zoology, Evolutionary Biology Centre, Uppsala University, Sweden.

Dr R. C. Banks
Zoologist Emeritus, USGS Patuxent Wildlife Research Center, Laurel, Maryland, USA; and Research Associate, National Museum of Natural History, Washington, DC, USA.

Dr J. M. Bates
Associate Curator of Birds, Field Museum of Natural History, Chicago, USA.

Dr K. S. Bostwick
Curator of Birds and Mammals, Cornell University Museum of Vertebrates, and Research Associate, Department of Ecology and Evolutionary Biology, Cornell University, New York, USA.

Dr M. de L. Brooke
Strickland Curator of Ornithology, University Museum of Zoology, Cambridge, England.

I. C. Caballero
Graduate student, Division of Birds, Field Museum of Natural History and Department of Biological Sciences, University of Illinois, Chicago, USA.

B. M. Clock
Assistant Curator of Visual Media, Macaulay Library, Cornell Laboratory of Ornithology, Cornell University, New York, USA.

A. Danks
Regional Leader Nature Conservation, Department of Conservation and Land Management, Albany, Western Australia.

Dr P. F. Donald
Senior Research Biologist, Royal Society for the Protection of Birds, Sandy, England.

A. Farnsworth
Graduate Research Assistant, Department of Ecology and Evolutionary Biology, Cornell Laboratory of Ornithology, Cornell University, New York, USA.

Dr J. W. Fitzpatrick
Director, Cornell Laboratory of Ornithology, Cornell University, New York, USA.

Dr B. J. Gill
Auckland War Memorial Museum, Auckland, New Zealand.

P. A. Hosner
Research Assistant, Cornell Laboratory of Ornithology, Cornell University, New York, USA.

Dr L. Joseph
Chair, Department of Ornithology, Academy of Natural Sciences, Philadelphia, Pennsylvania, USA.

Dr E. de Juana
Departamento de Zoología y Antropología Física, Universidad Complutense de Madrid, Spain.

Dr G. M. Langham
Graduate Research Assistant, Cornell Laboratory of Ornithology; Post-doctoral Fellow, James Cook University, Queensland, Australia, and University of California, Berkeley, California, USA; and President, Neotropical Grassland Conservancy.

D. J. Lebbin
Graduate Research Assistant, Department of Ecology and Evolutionary Biology, Cornell Laboratory of Ornithology, Cornell University, New York, USA.

Dr A. Lill
Associate Professor, Monash University, Victoria, Australia.

Dr J. A. Mobley
Research Associate, Cornell Laboratory of Ornithology, Cornell University, New York, USA.

M. B. Robbins
Ornithology Division, University of Kansas Natural History Museum, Lawrence, Kansas, USA.

Dr P. G. Ryan
Percy FitzPatrick Institute of African Ornithology, University of Cape Town, South Africa.

E. Scholes III
Visiting Fellow, Cornell University Museum of Vertebrates, Cornell University, New York, USA.

Dr D. W. Snow
British Museum (Natural History), Tring, Hertfordshire, England.

Dr F. Suárez
Departamento de Ecología, Universidad Autónoma de Madrid, Spain.

J. G. Tello
Graduate Student, Division of Birds, Field Museum of Natural History and Department of Biological Sciences, University of Illinois, Chicago, USA.

Dr A. K. Turner
School of Biology, University of Nottingham, Nottingham, England.

Dr S. J. Tyler
Ornithological Consultant; and Council member of BirdLife Botswana.

Dr B. A. Walther
Post-doctoral researcher, Zoological Museum, University of Copenhagen, Denmark.

Dr K. J. Zimmer
Research Associate, Los Angeles County Museum of Natural History, USA.

CONTENTS

Foreword ..... *R. C. Banks* 13

Introduction 27

Order PASSERIFORMES

Family COTINGIDAE (COTINGAS) ..... *D. W. Snow* 32

Species accounts of Cotingidae

M. de L. Brooke (*Oxyruncus*), *B. A. Walther* (*Phytotoma*)
& D. W. Snow (all other genera)

Family PIPRIDAE (MANAKINS) ..... *D. W. Snow* 110

Family TYRANNIDAE (TYRANT-FLYCATCHERS) ..... *J. W. Fitzpatrick* 170

Species accounts of Tyrannidae
(for specific contributions, see facing page):

J. W. Fitzpatrick, J. M. Bates, K. S. Bostwick,
I. C. Caballero, B. M. Clock, A. Farnsworth,
P. A. Hosner, L. Joseph, G. M. Langham, D. J. Lebbin,
J. A. Mobley, M. B. Robbins, E. Scholes, J. G. Tello,
B. A. Walther & K. J. Zimmer

Family ACANTHISITTIDAE (NEW ZEALAND WRENS) ..... *B. J. Gill* 464

Family ATRICHORNITHIDAE (SCRUB-BIRDS) ..... *A. Danks* 474

Family MENURIDAE (LYREBIRDS) ..... *A. Lill* 484

Family ALAUDIDAE (LARKS) ..... *E. de Juana, F. Suárez & P. G. Ryan* 496

Species accounts of Alaudidae
(for specific contributions, see facing page):

P. G. Ryan, E. de Juana, F. Suárez,
P. Alström & P. F. Donald

Family HIRUNDINIDAE (SWALLOWS AND MARTINS) ..... *A. K. Turner* 602

Family MOTACILLIDAE (PIPITS AND WAGTAILS) ..... *S. J. Tyler* 686

Foreword

Ornithological Nomenclature

Ornithological nomenclature is a branch of zoological nomenclature, and is thus "the system of scientific names applied to taxonomic units ... of extant or extinct" birds (International Commission on Zoological Nomenclature [ICZN] 1999: Art. 1.1). The words "nomenclature" and "taxonomy" are often used interchangeably, but if nomenclature is taken as the application and use of scientific names, taxonomy is the study of populations to determine which of them are sufficiently distinct to merit scientific names. Systematics, then, may be considered the study of the relationships between, and classification of, those named taxonomic units. It is impossible to discuss nomenclature without also discussing taxonomy, and it is nearly if not actually impossible to write more than a few sentences without using the words in different and overlapping ways. Nomenclature is the result of taxonomic decisions or actions.

Writing an essay on a subject that has been around as long as nomenclature is not as easy as one might think. In reviewing literature to develop ideas that I wanted to write about, I found that nearly everything I considered discussing has already been said, much better than I could possible hope to write it. For example, the development of the International Code of Zoological Nomenclature (hereafter, the Code) and of the earlier American Ornithologists' Union [AOU] Code dedicated to avian nomenclature are well and extensively chronicled in introductions to those documents (ICZN 1961, 1985, AOU 1886). Further, Bock (1994) has given a detailed history of nomenclature, emphasizing the family-group level. Melville (1995) has traced the history of the Commission. My only hope for a semblance of originality is that many readers of this Handbook will not have ready access to, or will not have found the time to read, that historical information. Here I can hope only to summarize, and to avoid plagiarizing, those important documents. If there is anything of interest in this discussion of the development of rules for avian nomenclature, I recommend that you delve into the sources just cited.

Beginnings of Ornithological Nomenclature

There is no record of when members of some early population of mankind first agreed that a particular sound that they each made would invoke the concept of some particular kind of bird and distinguish it from other kinds of birds. It might have been to designate a scavenger that competed with them for the remains of carcasses, or the imitation of a nocturnal sound associated with a form occasionally seen flitting across the moonlit sky. When all those in the community used the same sound — a grunt, or syllable, or "word" — for the same avian concept, avian nomenclature had begun. And when members of two communities met and realized that they used different sounds for the same bird, or the same sound for different birds, problems in avian nomenclature had begun. These primitive designations eventually developed into what are now called Common or Vernacular names, of which there can be one or more sets for each human language. There are still differences, and to some extent problems, between and even within languages, despite efforts to standardize names (e.g., Eisenmann & Poor 1946, Smith 1992; see entries under "Name" in Campbell & Lack 1985).

Early technical nomenclature fared no better as it developed from vernacular nomenclature. Some vernacular names from Latin and Greek, in particular, became the basis for scientific names because writings by the early philosophers and scientists

who used those languages have persisted. The first modern naturalists are generally perceived to have been scholars, educated in the Latin and Greek languages as a matter of course, using Latin as the primary language of science. Man's nature is to group things, and the early writers whom we might consider the first scientists grouped objects, including kinds of birds, that seemed to share characteristics. Thus many Latin vernacular names came to be used as group names, now considered generic names. Each of the great early naturalists used meaningful group names and specified kinds within the group by a series of descriptive or geographical modifiers. Many — probably most — species of birds, as well as other organisms, received more than one such "scientific" name, usually (but not always) bestowed by different workers studying different material at different times and places.

Linnaeus is credited with having originated the binomial system of nomenclature used today in all phyla of biological life. In this system, the scientific name of a species of organism is composed of two parts. The first word is the name of a genus, with a capital initial letter. The second word is the species name, written entirely in lower case letters; Recommendation 28A of the Code urges authors not to use a species-group name as the first word of a sentence, in order to avoid having to capitalize the initial letter. All names at the generic rank or lower are printed in italics to set them apart from other text. Linnaeus began using generic names in botany as early as his *Genera Plantarum* in 1737, and some zoologists were also using generic names as early as the 1730s. He promulgated rules for binomial nomenclature in 1751 and further developed the concept with his *Species Plantarum* in 1753. With the 10th edition of *Systema Naturae* in 1758, Linnaeus consistently used binomial nomenclature for all animals, and the practice took root from that moment, though with some notable exceptions (see, e.g., Bruce, HBW 8, pp. 17-20). However, naturalists in the century after the 10th edition often coined their own binomial names for species, with little knowledge of, and perhaps regard for, names set forth by others. There were no consistent rules for uniform application of names. Of course, in today's world of instant worldwide communication, it is often easy to forget the complications and time involved in past times in the spreading of word from one part of the world to another.

Origins of the Code

Ornithologists have had much to do with the formulation of rules embodied in the present code of nomenclature. The British Association for the Advancement of Science appointed a committee to develop some rules to regulate zoological nomenclature. The committee included Charles Darwin, among other notables of the day. Ornithologist (and geologist) Hugh E. Strickland was the "reporter" for the committee, probably the secretary in modern terminology, and probably the primary author of the resulting "Series of Propositions for Rendering the Nomenclature of Zoology Uniform and Permanent." This report was adopted by the British Association in 1842. It was soon adopted also by the American Association for the Advancement of Science and by similar bodies in other nations. Modified in various ways through the decades, the Stricklandian Code, as it became known, was followed "with more or less reservation and evasion by naturalists at large" into the 1880s (AOU 1886: 4).

When the American Ornithologists' Union was founded in 1883, one of the first committees established was that on Classification and Nomenclature. At that time, American ornithologists had their choice of at least four differing lists of American birds, by Spencer Baird from 1858, Robert Ridgway in 1880, and Elliot Coues in 1873 and 1882. The task of the committee (which included both Coues and Ridgway) was to amalgamate these lists into one that would be acceptable to all North American workers. The committee found it necessary first to examine the principles of zoological nomenclature, and the rules and practices of avian nomenclature in particular. This led to the formation of a "Code of Rules" for the guidance of the committee in fixing the name of every North American bird. The "Principles, Canons, and Recommendations" that formed the AOU Code of Nomenclature were published as a preamble to the first Check-list of North American Birds in 1886. Because this code was the first dedicated particularly to avian (rather than all zoological) nomenclature, and because it had an influence on the development of the present International Code of Zoological Nomenclature, we may examine it in some detail.

The AOU Committee took the Stricklandian Code as its point of departure, intending "to reaffirm and reproduce as many of its rules as may be desirable ... and then to build upon such a foundation with those additional recommendations and suggestions which in the judgment of the Committee are required to meet the demands of the present state of zoological science, and which seem most timely in view if its evident tendency, and probable progress in the future." The main departures from the earlier

Stricklandian Code were (1) the adoption of the date of the 10th edition of the *Systema Naturae*, 1758, instead of that of the 12th, 1766, as the starting point for the law of priority and therefore official nomenclature; (2) the rule that prior use of a name in botany does not make that name unavailable in zoology; and (3) adoption of the principle of trinomial nomenclature, providing for the nomenclatural recognition of subspecies. These departures are discussed in some detail below.

Linnaeus (and others) had used binomial nomenclature to some extent in earlier works, but it was not until the 10th edition of *Systema Naturae* in 1758 that the system of a distinctive generic and specific name for each species was used consistently in a single work. In the 12th edition, in 1766, many more species were included and names of some of the species in the 10th were changed. It is said that in the original draft of the Stricklandian Code, the number of the edition of *Systema Naturae* designated as the start of the law of priority, and thus binomial nomenclature, was left blank, and "twelfth" or "XIIth" was filled in by the committee approving the report. Even though it was recognized that binomial nomenclature had begun in earnest with the 10th edition, the 12th was maintained in the rules for many years because changing to the earlier date would require many changes of names and cause much confusion. The AOU committee, however, disagreed with that reasoning and selected the 10th edition. Its reasons were: (1) "the Xth edition is the one in which Linnaeus first introduced the binomial nomenclature, and in which its use is uniform, consistent, and complete;" (2) "This date [1758] admits to recognition the works of Artedi, Scopoli, Clerck, Pallas, Brünnich, Brisson . . . ", who had published important binomial taxonomic works between the 10th and 12th editions of Linnaeus and whose names used by Linnaeus in the 12th would thus be attributed to him rather than to their true authors; (3) the 10th rather than the 12th was in fact accepted as the starting point by a majority of naturalists in North America and Europe; (4) using the date 1758 resolved many questions of synonymy or homonymy which arose because Linnaeus changed in the 12th edition some names he had used in the 10th (Sherborn 1899); (5) the context of the draft of the Stricklandian Code implied that the 10th edition was intended to be the starting point, but that the 12th was inserted arbitrarily when the edition number was left blank; and (6) adoption of the 10th edition required very few changes in nomenclature then in use in most fields of zoology. Recognition of the 10th edition as the starting point was accepted universally when the present International Code was formalized.

The Stricklandian Code related only to zoology, and was silent on any relationship with botanical nomenclature. The restriction to zoological nomenclature was affirmed in various committee decisions in following decades. The AOU Code also related only to zoology, and indeed specified that there was "no necessary connection" between the two nomenclatural systems, and that use of a name in botany did not preclude its use in zoology, or vice versa. This was accompanied, however, by a strong recommendation that zoologists avoid using names already in use in botany.

The AOU Code did not introduce the concept of the subspecies, but it was the "first formally to enunciate the principles of the new method" of trinomial nomenclature for those forms that are known to intergrade in physical characters. The trinomial system was not a replacement for, but an extension of, the binomial system, which was to continue in use for those forms that are not known to intergrade. Trinomial nomenclature consisted of dealing with an organism of a population known to intergrade with another by applying to it three names, "one of which expresses the subspecific distinctness of the organism from all other organisms, and the other two of which express respectively its specific indistinctness from or generic identity with, certain other organisms; the first of these names being the subspecific, the second the specific, and the third the generic designation ..." Adding a third part to the binomial name "amplifies, increases the effective force of, and lends a new precision to, the old system." Most of us today would do well to reflect that the generic name indicates "identity" in certain distinctive characters with other species, the species name indicates "indistinctness" from populations that intergrade or vary clinally, and the subspecific name indicates "distinctness" of a population in morphological characters because of geographic and environmental conditions (AOU 1886: 16, 30-31). This might also be taken as an early formulation of the biological species concept. The third name used was, under the AOU Code, to be formed in the same way as, and subject to the same rules as, the specific name, as is the practice today when the two names are treated together as "species-group" names in the International Code of Zoological Nomenclature. The latter Code recognizes that the use of a name at the species or subspecies level reflects a taxonomic decision, and does not consider the use of a trinomial as a deviation from binomial nomenclature.

One may see other forms of a scientific name that appear to differ from the binomial form. The name of a subgenus (with a capital initial letter) may be interpolated, in parentheses, between the generic and specific names; it is not counted as part of the

binomen (Code, Article 6). Amadon (1966, 1968) introduced the concept of a superspecies, consisting of closely related but geographically separate allospecies. The name of the superspecies (the senior of the allospecies names) would be placed in square brackets before the name of the species. This system has been adopted by Sibley and Monroe (1990), among others. Similarly, Amadon and Short (1976) advocated the designation of megasubspecies, to be indicated (where used) by a species-group name interpolated in parentheses before a species name, to set apart a group of subspecies sometimes or potentially recognized as the species level. This burden on the concept of a binomial name has not come into general use, although it survives in the "group" names used by Sibley and Monroe (1990) and the AOU (1983, 1998). These interpolated names, when used, relate to classification rather than nomenclature, and are not counted as part of the binomial or trinomial name.

In addition to the Stricklandian and AOU Codes, national codes were adopted in France and Germany in the late nineteenth century. With the convening of the first International Congress of Zoology in 1889, a set of rules was proposed, but not adopted, for international use. A set of French rules was adopted at the second Congress (1892), and at the third Congress (1895) an international commission was appointed to study all existing rules and to develop a truly international code (see Melville 1995). At the fifth Congress in 1901, parts of that commission's report were accepted, and that action is regarded as the adoption of a code, published in 1905 as the *Règles internationales de la Nomenclature zoologique* in French, with English and German translations. The *Règles* have been modified and amended throughout the century, but in essence they are still in effect today as the International Code of Zoological Nomenclature, now in its fourth edition. The full history of the present Code has been set forth in greater detail in the prefaces and introductions to the various editions of the Code (ICZN 1961, 1985, 1999) and by Bock (1994). The Commission continued under the auspices of the International Congresses of Zoology until they ceased in 1972, when authority for it was transferred to the International Union of Biological Sciences (Melville 1995).

The International Trust for Zoological Nomenclature was established in 1947 to handle the finances of the Commission. The Trust is a registered charity under United Kingdom law and thus is free of taxes on income, including that from sales of publications such as the Code (Melville 1995). The Trust still is largely dependent on contributions. It exists to manage funds in support of the Commission, and serves as its publishing arm. It publishes the quarterly *Bulletin of Zoological Nomenclature* and the *Official Lists and Indexes of Names in Zoology* as well as the Code. At the time of writing, the Trust has announced a plan to raise a significant endowment to ensure its continued ability to support the work of the Commission.

Applying the Code: Rules and Categories

The Code is based on several principles, some of which follow almost precisely those listed by the AOU in 1886. The Code does not infringe on an individual's taxonomic judgement. Nomenclature does not determine the rank given to any assemblage of animals, but rather, through the process of typification, provides the name to be used for a taxon at whatever limits or rank are given to it. Every name covered by the Code is permanently attached to a name-bearing type. For species and subspecies, the type is a single specimen (preferably) or a particular set of specimens. For genera and subgenera the type is a species, and for families the type is a genus. The Code does not apply to groupings above the family level. The Principle of Priority determines (with some exceptions) what name is valid in any rank in which a population or assemblage is assigned by the individual taxonomist or systematist. Such an assemblage can have only one valid name, and the same name cannot be used for more than one taxon.

The goal of the Code is to promote stability in nomenclature; the primary way this is accomplished is by the Principle of Priority. The first name properly applied to a taxon remains the correct name for that taxon. The beginning date for purposes of priority is 1 January 1758, deemed to be the date of publication of the tenth edition of Linnaeus's *Systema Naturae*. For this reason, Linnaeus is credited with naming more currently recognized (by Sibley and Monroe 1990) species of birds than anyone else — about 710 (A. P. Peterson, pers. comm.). To be "available", a name must be properly formed and published in accord with criteria set forth in the Code (Art. 10). New names proposed after 1999 must be explicitly indicated as being new (Art. 16). This new provision is intended to prevent the accidental naming of a form, as has happened in the past at times when a name and sufficient diagnostic information has been published in a newspaper or other news item about a discovery of a new species.

Names at the family-, genus-, and species-group level are based on types. Family-group names are composed of the stem (or root) of the name of the type genus with a

suffix appropriate to the level of the name— -oidea for a superfamily, -idae for a family, -inae for a subfamily, -ini for a tribe, and -ina for a subtribe (Art. 29.2). A family-group name can be used at any, or all, of these levels, but not all levels need to be used in any classification. If two or more genera, each being the type genus of a family name, are combined into a single family, the earliest name at the family-group level has priority and cannot be replaced by a later-proposed family-group name. Bock (1994) has provided a detailed analysis of family-group names in birds, including a few exceptions to the law of priority at that level.

The type of a genus (or subgenus) is a species, but the name of the genus is not based on the name of the type species. In most of the recently named genera, the type species was designated when the genus was named. In many early works (e.g. Linnaeus), generic names were used without a type species being indicated, as the concept of types for genera was not introduced until the Stricklandian Code appeared. If a genus was established for a single species, that species is the type by monotypy. To be sure of stability of generic names, type species for other genera were established by subsequent designation, many of those in birds being proposed by G. R. Gray (1840, 1855). In instances where the name of an included species was used also in a generic sense (often by Brisson), that species became the type species by tautonomy. This becomes rather more complicated in the case of "Linnaean tautonymy": when a new genus is first introduced, if one of the species originally included in it has as one of its listed synonyms a pre-1758 single-word name that is identical to the name of the new genus, it becomes the type species. For example, among the eleven species in Linnaeus's (1758) genus *Strix* was one he named *stridula*. His reference base for that species was a pre-binomial, seventeenth-century use of the name "Strix" by Aldrovandus, where the single word was used to denote a particular species. Thus, *stridula* is the type species of *Strix* by tautonomy, although it is now considered to be a synonym of *Strix aluco*. If two authors name genera with the same type species, the later-named genus is a junior objective synonym. If two authors name genera with different type species that are later considered to be congeneric, the later name is a junior subjective synonym of the first that might be used at a subgeneric level or again at the generic level if the two species are again determined to be distinct at that level. Thus, the level of a genus-group name depends on the individual ornithologist's classification of the type species. Although a few species of birds distinctive enough to warrant separate generic status may yet be discovered, and new genera might be erected for species already known but in the future considered to warrant generic separation, for instance on biochemical grounds, it is reasonably safe to say that generic names in birds are now well established, although the number to be recognized will continue to fluctuate as the relationships of species are re-evaluated. Charles Sibley once told me that there are more names of genera available for hummingbirds than there are species in that family.

The type of a species-group name is an individual bird (holotype) or a series of individuals (syntypes). For species-group names proposed after 1999, a holotype or a series of syntypes must be designated and, if preserved specimens, the name of the collection where the specimens are or will be deposited must be given (Article 16). As the name-bearing specimen, the type defines the species (or subspecies). Non-taxonomists may tend to think that the type specimen is a "typical" member of the species, but no individual can really be typical in all respects. A species is composed of individuals of both sexes and of several age groups that represent the entire range of variation in the species in size, proportions, color, vocalizations, and behavior. No holotype can demonstrate all this variation; it is doubtful that a type series can do so. Still, a type specimen should be easily recognizable as a member of the species for which the name stands.

If a name is based on a series of specimens, with no one designated as the holotype (Articles 72, 73), all members of the series are syntypes. If one individual is designated as holotype, the others in the series are paratypes. It sometimes happens that a type series is composed of members of more than one species or subspecies. If an individual has been designated as a holotype, that specimen is the standard of the name. If there is no holotype and the identity of the taxon is in doubt, one of the syntypes may be designated a lectotype; it serves the name-bearing function of the holotype. The other syntypes then become paralectotypes. If no name-bearing type or member of the original type series is believed to be extant, and it is necessary to fix the identity of a taxon, a neotype may be designated. Designation of a lectotype or neotype is seldom necessary in ornithology, and these actions are strictly regulated by the Code (Articles 74, 75).

The type locality of a species is the locality from which the name-bearing specimen(s) originated. If no holotype has been designated, the type locality encompasses the localities of all syntypes. Under certain circumstances, a stated type locality may be modified (restricted) or corrected. For example, many South American birds have Bogotá [Colombia] as the originally designated type locality, but Bogotá was the place from which specimens taken in a large surrounding area were shipped to Europe, not neces-

sarily the precise origin of the specimens (Chapman 1917). If the type locality of a species is general or vague, a student of geographic variation who wishes to name additional subspecies of the species must attempt to make the original type locality more specific or restricted. Linnaeus (1758) based the name of the American Blue Jay, now *Cyanocitta cristata,* on a painting by Mark Catesby, giving the locality only as "America septentrionali," or northern America. That locality was restricted to "Carolina" (AOU 1910) and further restricted to "southeastern South Carolina" by Oberholser (1921) when he named the more northern birds *Cyanocitta c. bromia.*

Historically, many species of birds were first named on the basis of illustrations. Linnaeus (1758) named many species on the basis of paintings by Catesby, Edwards, and others. Although the painting (or other illustration) is often spoken of as the type, the actual type is the bird that was illustrated. The identity of the population from which the illustrated bird originated is in most cases known or at least accepted by now, but nomenclatural problems can arise if concepts of geographic variation change. The name of the Black-bellied Whistling-duck, *Dendrocygna autumnalis*, was based by Linnaeus (1758) on a plate and description by Edwards (1751) from the West Indies, possibly Jamaica. Most authors considered the illustrated bird to be representative of the populations in Central and North America, and a second species, *Dendrocygna discolor*, later considered a subspecies of *D. autumnalis*, was described from South America by Sclater and Salvin (1873). Subsequent re-examination of patterns of variation and of distribution led to the realization that Edwards had actually illustrated a bird of the South American form, hitherto known as *discolor*, that had been translocated to Jamaica. As a result, the first species-group name, *autumnalis*, replaced the name *discolor* for South American birds, and a much later name, *fulgens*, had then to be applied to the Central and North American birds (Banks 1978; compare treatments of the species by Peters (1931: 153) and Johnsgard *in* Mayr and Cottrell 1979: 430).

A tendency has developed in recent decades to name species or subspecies of birds without a preserved specimen, basing the name instead on living birds or on photographs (e.g., Welch and Welch 1988). The negative aspects of that practice were discussed by Vuilleumier and Mayr (1987) and by Banks *et al.* (1993, for many others), and recommendations were proposed to avoid future such occurrences. The most recent Code (ICZN 1999) states (Art. 72.10) that "Holotypes, syntypes, lectotypes, and neotypes are the bearers of the scientific names of all nominal species-group taxa (and indirectly of all animal taxa). They are the international standards of reference that provide objectivity in zoological nomenclature and must be cared for as such ... They are to be held in trust for science by the person responsible for their safe keeping." A wild bird that is photographed can be the "type" of a name — but it can fly or even walk away, never to be seen again. In that instance, there is no person responsible for its safe keeping. The person who houses the photograph cannot be responsible for the individual that was the subject of the photograph. The person who established the name based on an itinerant individual bird cannot logistically or reasonably assume responsibility for the safe keeping — whatever that concept may entail — of a wild bird. One might conclude that it is irresponsible to designate a type that cannot possibly be provided any degree of safe keeping by anyone. If a wild bird that is temporarily restrained for the purpose of photography becomes the type of a name based on a photograph, it is not responsible safe keeping of the "specimen" to release it into the wild. Payne (1989) has discussed an instance of a name based on photographs.

When a name is based on a photograph, the type is the individual photographed; after a period of time, the type is "lost." Therefore it would be permissible to designate a specimen with those characteristics as a neotype under the appropriate condition, when "an author considers that a name-bearing type is necessary to define the nominal taxon objectively" (Article 75.1). Thus, if a species is revised and the status of a name or of a taxon based on a photograph is in doubt, the reviewer can designate a neotype. If this is done, the photograph on which the name was based loses its value. Thus, any photograph of a bird is liable to become worthless from a nomenclatural standpoint. Perhaps one of the strongest arguments against the use of photographs in this way comes from recent advances in the form of digital photography, which would make it all too easy for the unscrupulous to "invent" a species simply by manipulating photographs on a computer.

Applying the Code: Naming Birds

Most genera and species of birds have already been described and named; indeed, many have been named several times. Mayr (1957) suggested that probably no more than 20 species would be named in the next decade. Even though he later (Mayr 1971) realized that the number of new species was "by no means nearly exhausted," and

new species are being found until this day, the primary taxonomy of birds (except fossils) must be nearing an end. Most work in avian nomenclature in the future will not involve the coining of new names, but rather will concern the proper treatment of names of populations whose taxonomic status is changed because of new evidence about their relationships. Much of this will involve the elevation of what are now considered subspecies to the species level, the moving of a species from one genus to another, or moving a genus (with most or all of its included species) from one family to another. Each of these actions has been taken recently (Banks *et al.* 2003) to reflect new information provided by studies of genetics. The name of the population moves with it, but taxonomic changes may necessitate nomenclatural modifications. If a species is moved from one genus to another, the spelling of the species name, or that of a subspecies, may have to be changed slightly to reflect agreement in gender with the name of the newly assigned genus. For example, if the Snowy Owl, long known as *Nyctea scandiaca*, is transferred to the genus *Bubo*, as recommended by Wink and Heidrich (1999), the name becomes *Bubo scandiacus*. There is a possibility that the species (or subspecies) name might already be (or have been) in use in the newly assigned genus, in which case an older name may have to be resurrected or a new name may have to be coined. When the Fork-tailed Flycatcher, known as *Muscivora tyrannus* (Linnaeus, 1766), was moved into the kingbird genus *Tyrannus* by Smith (1966), the combination *Tyrannus tyrannus* (Linnaeus, 1766) was preoccupied by *Tyrannus tyrannus* (Linnaeus, 1758) and the flycatcher became known as *Tyrannus savana* Vieillot, 1808, using the next available specific name.

On the assumption that few new species names will be coined, it seems unnecessary to write a great deal about how that should be done. LeCroy and Vuilleumier (1992) have published guidelines for that procedure that should be consulted by everyone contemplating naming a new species. Helbig *et al.* (2002) give suggestions for the determination of the rank at which a new (or old) form might be recognized. The Code (ICZN 1999) sets forth the rules of nomenclature in sometimes excruciating detail. An ornithologist who spends much of his professional time on taxonomic and nomenclatural matters should become (if not already) conversant with the Code. Those ornithologists who find it necessary as a result of their studies to propose a nomenclatural change should become familiar with the Code or form an alliance with one who is knowledgeable, or both. Editors of journals that publish papers about birds should be alert to changes in nomenclature that may form a part of newly submitted manuscripts, and should refer such papers to a colleague who is trained and competent in nomenclatural matters.

Perhaps the hardest to reach with an admonition is the worker who is barely aware that a code of nomenclature exists, and who in excitement at finding something new inadvertently publishes enough information about his or her find in a non-typical publication outlet (such as a newspaper), thereby almost or actually constituting a naming of a taxon. Article 16 of the current Code (fourth edition, 1999) sets forth very explicit requirements for new names published after 1999, which should avoid accidental namings. It is best if a scientific name is not mentioned before the intentional formal description of a new taxon. It might find its way into print, where, even if not accidentally validated, it will be a *nomen nudum*, a new name unaccompanied by a description or definition (Article 13). For example, when a population of Sage-grouse was discovered in Colorado, USA, that was notably smaller than typical Sage-grouse (*Centrocercus urophasianus*), a decision was made to refer to it by the name *minimus*. The combination *Centrocercus minimus* was used at least twice in papers about the biology of the population (e.g. Commons *et al.* 1997) and once as a passing reference to identify a picture of the bird before the name was formally proposed as a new species (see Banks *et al.* 2002: 899). However, a *nomen nudum* is not available and has no standing in nomenclature, and thus can be used later for the same concept (Code, Glossary), as in this case by Young *et al.* (2000), when the new Sage-grouse was formally named.

A name that is found to be based on a hybrid is not valid and cannot be used for any taxon, even one of the parental species (Articles 17.2, 23.8). Such a name remains available, however, and can be a homonym (see below). Rasmussen and Collar (1999) determined that the name of the supposedly endangered parrot species *Psittacula intermedia* (Rothschild, 1895) was used for birds of hybrid origin. This is not a valid species, and the name *intermedia* cannot be used again in combination with that generic name (or the former generic name *Palaeornis*, in which it was originally described, should that name be revived). What might seem contradictory is that the "availability" of the specific name in this instance means that it cannot again be used in combination with either generic name; those combinations are "taken" and cannot be used for a different entity. The second use of the combination would create homonymy, use of the same name for two different taxa. This contrasts with the Sage-grouse example in the paragraph above.

A few basic rules must be mentioned, to aid in the naming of new species and generic transfers. A genus-group name is, or is treated as, a Latin noun in the nominative singular (Art. 11.8). A Latin noun connotes a gender (masculine, feminine, or neuter), and the gender of a genus-group name is determined by provisions set out in Article 30. Recently, David and Gosselin (2002b) have reviewed currently used generic names of birds and have determined or verified their gender by strict interpretation of those provisions. For any generic names proposed in the future, the derivation and gender should be specified. If new information on relationships necessitates the splitting of a genus and the revival of an old generic name, the gender of that name will need to be evaluated carefully.

The name of a species, or subspecies, must be (or have been) published in combination with a generic name and must be an adjective or participle in the nominative singular, a noun in the nominative singular standing in apposition to the generic name, a noun in the genitive case, or in some instances an adjective in the genitive case (Art. 11.9). A species-group name that is a Latin or Latinized adjective, or a participle in the nominative singular, must agree in gender with the generic name with which it is combined, and if transferred to a genus of a different gender must be changed to agree with the newly combined genus, as mentioned above. A species-group name that is a noun in apposition is invariable and does not necessarily agree in gender with the generic name. A name that is not Latin or Latinized does not change and need not agree in gender with the generic name. As with genera, rules for determining the nature of species-group names are detailed in the Code (Art. 31). Even so, some of the rules are difficult to apply properly, especially if one does not have a working knowledge of classical languages. David and Gosselin (2000, 2002a) have reviewed most current species-level names and have determined which should be considered invariable.

If the same name is applied to more than one entity at the same taxonomic level, the names are homonyms. The name proposed later, or junior homonym, is said to be "preoccupied" and must be replaced by another name. If one must coin a name for a new genus, therefore, one must be certain that it has not been used previously — not only in ornithology but in any animal group. In naming a species or subspecies, one must be certain that the name has never been used in the genus. It is best if the name has not been used in a closely related genus, to reduce the risk of creating secondary homonymy if the genera are later merged.

To avoid the inadvertent use of a generic name that has already been used, one may consult the official list of names that have been ruled on by the International Commission on Zoological Nomenclature (ICZN 1987, 2001). Avoiding homonyms at the species-group level is possible by being familiar with the names in use in the genus, as a specialist should be, or by consulting synonymies in such works as the Catalogue of Birds in the British Museum or Ridgway's Birds of North and Middle America, as far as it goes. One must avoid not only names that are currently accepted as valid for a taxon, but any name that is available even if presently considered a synonym of a current name. John Penhallurick of Australia is working on a bird data project (http://worldbirdinfo.net/) that will eventually list all combinations of generic and specific names of birds that have been used. When completed, this will be an extremely valuable tool, among other things for avoiding the creation of homonyms.

There are a few situations in birds where more than one spelling of a name is, or might be, in use. Browning (1989) showed that Swainson's generic name generally rendered as *Ptilogonys* was originally spelled *Ptiliogonys*. However, Swainson himself in various writings used both spellings, and the original form has not been used since 1887. Sibley and Monroe (1990) suggested that *Ptiliogonys* should be considered an incorrect original spelling and *Ptilogonys* a justified emendation, a course of action followed by the American Ornithologists' Union (1998). Under the present fourth edition of the Code (1999), the concept of "prevailing usage" (Art. 23.9.1) allows *Ptilogonys* to be considered valid because the original spelling has not been used after 1899 (Browning 1989) and the present spelling has been used consistently.

In my view, the concept of prevailing usage is, in addition to being contrary to the principle of priority, difficult to apply in ornithology. The concept is defined (ICZN 1999, Glossary) as "that usage [including spelling] of the name which is adopted by at least a substantial majority of the most recent authors concerned with the relevant taxon, irrespective of how long ago their work was published." Explicit rules are set forth in Article 23.9. In many fields of zoology, names are mentioned only infrequently in the literature and then only by specialists who consciously decide at the time of writing which spelling to use. Even in those fields, it may be difficult to know where all uses of a name occur and to determine which of two alternatives was used by a majority of authors. In ornithology, names may be used in dozens or hundreds of non-taxonomic papers, field guides, and faunal lists by non-specialists who may use a

Table 1. The rate of descriptions of new bird species since 1920.

* estimated

particular spelling merely because it was used in some other recent paper, with no conscious consideration of articles of the Code and presumably with little nomenclatural "concern" for the particular taxon.

A new name should be proposed only when the author is certain that the population to be named is distinct from all other avian populations at the level at which it is named. Names based on minor variants or on samples that are too small to show distinction convincingly are probably destined for synonymies, and in essence do nothing but clutter the literature. In the past, it was possible to name a population that the author believed might prove to be distinct, as Baird (1859) did with *Myiarchus pertinax* of Baja California, Mexico. Such "conditional" names are not valid if proposed after 1960 (Code, Article 15).

Although it may be presumed that ornithologists believe that species they describe and name as new actually are "new" and distinct at the species level, the record shows that many are mistaken. In 1934, Meise (1938a) provided an analysis of 600 new species named from 1920 to 1934. He considered (Table 1) that only about 25% of the names proposed in that time were valid at the species level. Periodically since that time, new species names have been evaluated, by Meise (1938b) and by ornithologists at the American Museum of Natural History, New York (see Table 1 for references). From 1920 to 1990, more than 900 new species names were proposed, of which only about 30% were considered to be valid at the species level when analysed. The rates for valid species for any period may be slightly different because of differing taxonomic concepts. Some taxa recognized as valid species originally might now be considered only subspecifically distinct, or vice versa.

The number of species described per year declined greatly after 1941 (Table 1), perhaps a response to greatly reduced collecting during and after World War II, but remained relatively stable in the last part of the century. The proportion of species that were generally deemed valid soon after their descriptions increased in that period, and is now probably something in the order of 60-65%. Similarly, the annual number of newly described species that were considered valid by initial reviewers has held rather steady in the last half century, at about 3 per year. Most of the rest of the new names are considered synonyms of names already in use, while some are reckoned valid at the subspecies level. A few are invalid names, based on hybrids or otherwise not in compliance with the Code.

Norbert Bahr (pers. comm., June 5, 2003) has compiled a list of new taxa of birds described since 1970. Among the nearly 1300 taxa validly described are 170 named as new at the species level by 2000. In that 30 year period, the rate of naming of new species was 5.7 per year. The proportion of those described that are generally considered distinct at the species level has not been evaluated, but if it is the same as for 1981-1990 it would yield about 3 species per year.

Bahr's figures suggest that about 1100 birds were newly described at the subspecific level in 1970-2000, a rate of about 37 per year. To my knowledge, there has been no independent evaluation of the validity of most of those names, and opinions are likely to vary widely.

What's in a name?

What should be the source of a name for a bird population? This is entirely at the discretion of the namer. The Code is silent on the source of the name, but it should not have been used previously in the same (or a closely related) genus. Frequently used,

now as in the past, are names to honor people, names based on geography, and words that are suggestive of the bird or its characteristics (behavior, ecology, voice). Less frequently used are terms that indicate supposed relationships or similarities to other birds. The third edition of the Code (1985) gives recommendations (Appendix D) for the formation of specific names in most of these categories, unfortunately not reprinted in the fourth edition. Recommendations in the Code do not have the force of rules, but life is easier for all of us if they are followed. The Code (Article 31, 1999) does give specific rules for the formation of species-group names formed from personal names, or patronyms.

Alan Peterson (pers. comm.) has provided a list of species names used in currently recognized bird species, in order of frequency. The top 30 names, including those used 16 or more times, appear in Table 2. This list suggests the features of birds that are most important in their recognition or definition. These are size, color, features of the head, including the bill, and geographic origin.

The name *minor* is the most frequently used descriptor of size, occurring 26 times. At the other end of the scale, *major* is used for 15 species. If *maximus* and *minimus* (for adjectives that have variable endings to indicate gender, I give only the masculine in this section, to include also feminine and neuter endings) are taken into account, small birds slightly outnumber large ones, but there are many other words used to indicate size or relative size.

People who have named birds have been impressed by the variety, or lack of variety, of color on their subjects. The number and variety of colors has been important — *unicolor* and *bicolor* each appear 21 times, *tricolor* 16 times, and *quadricolor* and *quinticolor* each twice. The name *concolor* (9 times) presumably is the same as *unicolor*, suggesting that relatively drab birds outnumber multicolored ones, until *versicolor* (16), *discolor* (= variegated) (5 times) and *multicolor* (4) are considered.

The basic colors of birds are also reflected by their names. The most frequently used color descriptor is *cinereus* (40), followed by *olivaceus* (30), *niger* (27), *fuscus* (26), and *viridis* (25). I have not attempted to determine how frequently these colors occur in compound words.

Except for a notation of a crest (*cristatus*, 30) crown (*coronatus*, 22), or tail (*caudatus*, 11) the names of body parts generally do not appear without modifiers. Features of the head seem to be the most remarkable. Roots indicating head characteristics such as *-ceps* (135), *-cephal-* (116), and *-capill-* (71), often combined with color-indicating prefixes, are most frequent. The nature of the bill, *-rostr-* (182), in size, shape, or color, is often noted. The presence of a collar (*collaris* 103, *torquatus* 49) is also a frequently noted distinguishing character, alone or with a modifier.

Many species are known for where they occur or were first found. Senegal is the locality most frequently noted in a specific epithet, with 18 names in some form, mostly *senegalensis*. Six of the 13 species with the epithet *senegalensis* were named by Linnaeus (1766) in the 12th edition of *Systema Naturae*, suggesting that he had a fixation on that locality. However, all are based on the same names used by Brisson, whose pre-1766 work was not consistently binomial, denying him modern credit for names proposed in them. A similar situation holds for the frequently used (16 times) name *madagascariensis*, with variants. Linnaeus named 5 of 14 species with that epithet in 1766, and Gmelin added two in 1789, all using a name previously used by Brisson. Other place names with multiple uses are *americanus* (16), *mexicanus* (16), and *nipalensis* (16).

The individual most honored by having bird species named after him is P. L. Sclater, whose name is the basis of the current valid species name for 18 species (Table 3). The index volume for the Peters check-list (Paynter 1987) lists 74 species level entries based on Sclater's name, although a very small number of these may perhaps honour his son, W. L. Sclater. Some of the other 56 entries represent synonyms of presently accepted species names as combined with other generic names, whereas others are presently recognized at the subspecific level. A quick review of that index volume suggests that John Gould, with more than 40 entries, should be among the most recognized in avian nomenclature, but there are actually only three currently valid uses of his name as a species name. Perhaps somewhat ironically, neither Linnaeus nor Gmelin, compilers of the *Systema Naturae*, has a bird species validly named in his honor.

From the data base on his web site (www.zoonomen.net), Alan Peterson has tabulated the names of authors credited with establishing the largest numbers of names of currently recognized (Sibley and Monroe 1990, updated) bird species (Table 4). As the author of the first work to be considered for the law of priority, Linnaeus understandably takes top place, being credited with about 710 current species names. Not all of the 710 date from the 10th edition of the *Systema Naturae*, however. Some are from the 12th edition and a few are from other works. Even so, this is less than 10% of the approximately 10,000 species now recognized. Statius Muller (1776), in a

supplement to a German edition of Linnaeus, and J. F. Gmelin (1788/89), primarily in a 13th (= 14th, see Iredale 1958) edition of *Systema Naturae*, added 433 species, so it can be said that Linnaeus's work and expansions on it account for about 1143 names. A few other authors actively provided names for birds in the period between the 10th and 12th editions — Scopoli, Brisson, Pallas, and Brünnich, for example — and a few others, such as Latham, before the turn of the nineteenth century. Perhaps as many as 1400 species had been named by that time. There was then a quiet time in naming new bird species that lasted from shortly after Gmelin's 13th edition until about the 1820s, when Vieillot began to name a large number of taxa. Publication of large numbers of names continued until about 1900. There was some slackening until about the 1940s and World War II, after which the number of new names has been moderate and fairly regular.

Conclusion

This essay has covered only a few of the 90 articles of the International Code of Zoological Nomenclature. The Code is a complex document that still requires interpretation and refinement. It is not important that every ornithologist or birder who finds, or thinks he finds, a new taxon be an authority on the Code, but everyone who wants to name a new species or subspecies should be aware that there is a Code, and be willing to seek assistance in complying with it. Editors, in particular, should be alert to possible taxonomic implications in papers that they receive for publication, and be certain that at least one referee or reviewer is familiar with this aspect of our science. In the not-too-distant past there have been instances of birds being named, or almost named, by accident or in a non-scientific publication. Certain provisions of the current Code are designed to decrease the likelihood of that happening by requiring an explicit statement that a taxon is new, and that a type be designated and the place of its deposit be indicated. With just a little co-operation and forethought we can be assured that ornithological nomenclature will retain the high standards it is known for.

Description of a new tribe of fluvicoline tyrant-flycatchers

The subfamilial and tribal classification of the Tyrannidae remains inexact, as the mosaic of anatomical and behavioral character states most useful for diagnosing closely related assemblages of tyrannid genera contains numerous irresolvable conflicts. The most explicit attempt to integrate these various characters and character states into a phylogenetic hypothesis for the entire family (Birdsley 2002) yielded a strict consensus tree, bearing only rudimentary structure. Birdsley's work supports an earlier hypothesis by Lanyon (1984, 1985) that monophyletic "kingbird" and "*Myiarchus*" assemblages (tribes Tyrannini and Attilini, respectively) characterize the subfamily Tyranninae, and also supports the existence of a monophyletic "*Empidonax* assemblage" (Lanyon 1986). Unfortunately, most of the remaining tyrannid genera are arrayed along a massive polychotomy, bearing little information about deep relationships of genera. Moreover, Birdsley's analysis incorporated comparatively plastic characters such as plumage pattern (e.g. color of tail, presence of wingbars, etc.) and foraging mode. With these characters removed from his analysis, Birdsley's tree loses structure even further. Without doubt, detailed molecular analyses will be essential for sorting out phylogenetic relationships within the Tyrannidae at the level of tribe and subfamily.

Bearing in mind this caveat, our present taxonomic treatment of the Tyrannidae clusters genera into more or less recognizable subfamilies and tribes, following the suggestions of Traylor (1977) and Lanyon (1984, 1985, 1986, 1988a, 1988b, 1988c), applying the most appropriate names available from the existing literature, as capably reviewed by those authors. In sorting genera into these groups it came to our attention that one of the most familiar clusters of tyrannid genera lacks a formally proposed name. I describe it here. The following diagnosis and discussion applies to a portion of Birdsley's (2002) "restricted *Empidonax* assemblage" and to Lanyon's (1986) "*Empidonax* group". The anatomical characters mentioned here are described in detail in those publications. However, the exact list of genera included in the tribe is slightly modified from both, as discussed below. The name Contopini is proposed

because the genus *Contopus* comprises a numerically important element of the group, and because this name was informally suggested for this group in an unpublished, but landmark, doctoral dissertation by Warter (1965). Ecologically, this group is a rather homogeneous assemblage of forest-inhabiting tyrannids that sally upward and outward for prey either in the air (*Contopus* and relatives) or against leafy vegetation (the *Empidonax* group). The genus *Sayornis* represents an ecological and morphological transition to the other fluvicoline tribe, Fluvicolini, as described below.

Contopini — new tribe
Type genus: *Contopus* Cabanis, 1855

Diagnosis: sexually monomorphic tyrant-flycatchers (family Tyrannidae); external morphology includes triangular-shaped bill, comparatively broad at base tapering to pointed tip, bearing modest hook at tip of culmen; rictal bristles well developed; nest typically a neatly constructed open cup placed on horizontal limb or ledge, or slung from a fork in a horizontal branch; identifiable as belonging to the subfamily Fluvicolinae, principally in possessing a fully ossified nasal septum bearing a transverse trabecular plate located along the ventral edge of the septum, this plate in most cases lacking a sagittal ridge and possessing both an anterior notch and a posterior fork; identifiable to tribe Contopini by having syrinx with one or more complete or nearly complete calcified rings ("A elements" in terminology of Lanyon and Warter) on each bronchus posterior to tracheobronchial junction, sometimes medially cartilaginous and connected by a plug of cartilaginous tissue just caudal to tracheobronchial junction, and in one monophyletic group further modified for attachment of internal cartilage (see below).

Typical genera. The following genera are unambiguously included within the Contopini on the basis of conflict-free possession of the diagnostic characters: *Lathrotriccus*, *Aphanotriccus*, *Xenotriccus*, *Cnemotriccus*, *Empidonax*, *Contopus*, *Mitrephanes*, and *Sayornis*. These constitute Lanyon's (1986) "*Empidonax* group," and are united as a monophyletic clade most importantly by having the cartilaginous segments of the A2 syringeal rings modified for attachment of internal cartilage.

Atypical genera. The following genera are tentatively placed in the Contopini, but possess character conflicts that reduce our certainty about their inclusion. *Myiophobus* contains several species (*fasciatus, flavicans,* and *inornatus*) in which the nasal septum is consistent with the Contopini, but several other species in which the same characters are slightly different (e.g. absence of fork in trabecular plate); this genus may be polyphyletic (Lanyon, 1986). *Pyrrhomyias* and *Hirundinea* have nearly typical fluvicoline nasal septa, although their trabecular plate lacks a fork, and they cluster with *Myiophobus* on the basis of a derived syringeal character (one or two completely calcified rings around bronchi independent of tracheobronchial junction).

Genera *incertae sedis*. The genera *Myiobius, Terenotriccus*, and *Neopipo* have puzzled taxonomists for years (Mobley & Prum 1995). They cluster together on the basis of both cranial and syringeal characters; indeed, both Lanyon and Birdsley lumped *Terenotriccus* into *Myiobius*. The nasal septum of *Terenotriccus* and some specimens of *Myiobius* are of the derived fluvicoline type typical of the Contopini; the skull of *Neopipo* is lacking from collections. The syringes of all three genera, although different from one another in detail, are consistent with inclusion in the Contopini. However, these species construct pendant nests, which is otherwise absent within the Fluvicolinae and has been suggested as evidence for their relationship with the large group of pendant-nest builders in the Elaeniinae (especially *Cnipodectes* and *Onychorhynchus*). We treat these as transitional genera of uncertain affinity, and suggest that future research explore the possibility that the genera *Onychorhynchus*, *Cnipodectes*, *Myiobius*, *Terenotriccus,* and *Neopipo* (and perhaps several species of *Myiophobus*) constitute a tribe or subfamily of their own.

Fluvicolini. The remaining genera of the subfamily Fluvicolinae constitute the tribe Fluvicolini. These represent an assemblage of medium- to large-bodied, terrestrial and near-ground specialists occupying open country, with a clear center of radiation in the non-forested areas of South America, especially Patagonia and the high Andes. Within this tribe are several closely related groups hypothesized by Lanyon (1985, but see Birdsley, 2002) to be internally monophyletic on the basis of cranial or syringeal characters: the sexually dimorphic "*Knipolegus* group" (genera *Pyrocephalus*, *Lessonia,*

Knipolegus, and *Hymenops*), the large, mostly terrestrial "*Muscisaxicola* group" (*Muscisaxicola, Agriornis, Xolmis, Myiotheretes, Cnemarchus, Polioxolmis, Neoxolmis, Gubernetes,* and *Muscipipra*), and the "*Ochthoeca* group" (*Arundinicola*, *Fluvicola*, *Alectrurus*, *Tumbezia*, *Ochthoeca*, and *Colorhamphus*). Finally, two monotypic genera (*Ochthornis* and *Satrapa*) are unambiguously fluvicoline based on anatomical characters, but have ambiguous affinities within the Fluvicolini. Three additional monotypica genera traditionally grouped with this assemblage (*Colonia, Muscigralla*, and *Machetornis*) are morphologically, anatomically, and ecologically confusing, and are best considered *incertae sedis*.

John Fitzpatrick
Director, Cornell Laboratory of Ornithology
Cornell University, New York, USA

Acknowledgements

I thank Richard Banks and Walter Bock for their assistance with this manuscript; I thank Wesley Lanyon for his painstaking anatomical research and for his many long hours of discussion and debate with me about tyrannid systematics.

Introduction to Volume 9

This, the second of the passerine volumes, can be considered a taxonomically significant one. It includes the last of the suboscine families, the first of the oscines, and in between the three small Australasian families that have often been treated to some extent as transitional. From here onwards all the remaining families in the series are oscine, all occupying the same suborder that is generally agreed to comprise the most highly evolved of all the birds. It is also worth noting that Volume 9 covers the largest of all the bird families, in the shape of Tyrannidae, with some 429 species.

After eight volumes' worth of introductions, we have little of relevance left to say by way of explaining how the series works, so this time round we shall give the reader a break and limit ourselves to a few assorted brief notes on the subject of names.

With the great upsurge of popular interest in taxonomy and related subjects in recent years, we felt that it really was time that we had a foreword explaining some of the main principles and rules of nomenclature. To this end, we have been extremely fortunate that Richard Banks kindly agreed to contribute an essay on the subject, and we think readers will agree that he has covered the main details of this complicated subject with admirable clarity.

Staying with the same subject, this current volume has turned up quite a new situation for us. While working on the internal classification of the Tyrannidae for HBW, John Fitzpatrick noticed that one of the subdivisions that he intended to recognize did not have a formally proposed name. In order to remedy this situation in time for the "tribe Contopini" to be validly usable for HBW, John has written the formal description of this tribe for publication in the present volume (pp. 25-27), in this way making quite certain that the description could not be delayed and end up being published later than the HBW text for which it was required. While HBW might appear an odd medium for publishing a new scientific name, we would like to stress that we did check with various experts in the field, most notably Walter Bock, and all agreed that HBW meets the requirements more than adequately. Indeed, it was even mentioned that HBW is particularly appropriate in terms of one of the most important criteria of all, as the series is more readily accessible to a greater proportion of the broad ornithological community worldwide than are quite a number of important ornithological journals. Having the description written by one of the foremost authorities on the family Tyrannidae, and having it refereed by two of ornithology's most prestigious taxonomists, are guarantees that all efforts have been made to ensure that this description has been aptly and correctly formulated.

Before leaving the subject of nomenclature, we should like to make a further point. In recent times a great number of species-group names have undergone slight modifications, due to incorrect previous usage. This is the result of detailed studies aimed at clearing up many long-standing errors, and published in two papers:

David, N. & Gosselin, M. (2002a). Gender agreement of avian species names. *Bull. Brit. Orn. Club* **122**: 14-49.

and

David, N. & Gosselin, M. (2002b). The grammatical gender of avian genera. *Bull. Brit. Orn. Club* **122**: 257-281.

This work has led to the modification even of some rather well-known names, and a fair number of such emendations appear in the present volume.

Still in the field of bird names, though unrelated to the formal Code that regulates scientific nomenclature, the latest batches of accepted Spanish names to have been

published can be found in *Ardeola* **49(1)**: 121-125 (HBW 7) and *Ardeola* **50(1)**: 103-110 (HBW 8).

One final note that we should like to make must inevitably be connected with names too! At last, we have taken the decision that the name "Zaire" really has become obsolete. Thus, in accordance with current usage, in the present volume we have renamed the country in question as "DRCongo". This is not to be confused with the neighbouring country hitherto known simply as "Congo", and now for the purposes of HBW renamed as "PRCongo".

Acknowledgements

This has been another volume in which the contribution of museums has been particularly notable. Our first ports of call are always the British Museum of Natural History at Tring (Robert Prys-Jones, Michael Walters, Mark Adams), the American Museum of Natural History in New York (Joel Cracraft, George Barrowclough, Mary LeCroy, Paul Sweet, Shannon Kenney, Peter Capainolo, Maria Rios), the Louisiana State University Museum of Natural Science (Van Remsen, Steve Cardiff, Donna Dittmann, Dan Lane, John O'Neill), the Smithsonian Institution, National Museum of Natural History in Washington (James Dean, Gary Graves), and the Colección Phelps de Venezuela (Miguel Lentino, Margarita Martínez, Clemencia Rodner, Robin Restall). Other institutions that made very helpful contributions include the Australian Museum in Sydney (Walter Boles), the Departamento de Zoologia Universidade São Paulo (Luís Fabio Silveira, Fernando Mendonça d'Horta), the Bombay Natural History Society (Saraswathy Unnithan, Zafar-ul Islam), the Royal Museum for Central Africa in Tervuren (Michel Louette), the National Museum of Costa Rica (Julio E. Sánchez), the Museum of New Zealand Te Papa Tongarewa (Alan Tennyson), the National Museums of Scotland in Edinburgh (Bob McGowan), Liverpool Museum (Tony Parker), the Transvaal Museum (Tamar Cassidy), the Edward Grey Institute of Field Ornithology at Oxford University (Linda Birch), the Field Museum in Chicago (David Willard, Shannon Hackett), the Delaware Museum of Natural History (Gene Hess), the Museum of Comparative Zoology in Harvard (Alison Pirie, Peter Alden, Jeremiah Trimble), the Natuurhistorisch Museum at Leiden (René Dekker) and the Academy of Natural Sciences at Philadelphia (Nate Rice).

The task of sorting out all the details of the bibliography and references is a huge one, and relies heavily on help received from a whole host of different sources. We should particularly like to thank *Africa Birds & Birding* (Eve Gracie), David Allan, *Aves Argentinas* (Ignacio Roesler, Darío Unterkofler), the Bombay Natural History Society (J. C. Daniel), the British Museum of Natural History at Tring (Alison Harding, Lorraine Portch, Kamila Reekie), Murray Bruce, Normand David, Edward Dickinson, the Faculty of Natural Science and Museum of La Plata (Guillermo Soave), *Der Falke* (Einhard Bezzel), Georg Grothe, Juan Carlos Guix, HANZAB (Will Steele), Tomas Knotek, the Museum of Zoology of the University of Michigan (Janet Hinshaw, Janet Bell), the Ornithological Society of Bavaria (Juliane Diller), the Ornithological Society of New Zealand, Mark Robbins, the Sociedad Española de Ornitología (Blas Molina), *Western Birds* (Philip Unitt) and Piotr Tryjanowski. We must also make a special mention of the assistance received from Diego Calderón Franco; we are very sorry to have to report that at the time of writing he has yet to be released by his kidnappers, and we add our collective voice to the pleas for his safe delivery.

Our sincere thanks go to all those who have helped in so many different ways to improve the content of the volume, for instance by sending us unpublished information or refereeing texts, and in particular we must mention David Ascanio, Murray Bruce, Normand David, Jon Fjeldså, Mary LeCroy, Sjoerd Mayer, Petro Pynnönen, Craig Robson, Peter Ryan, Ian Sinclair, Barry Walker, David Wells and Bret Whitney.

Several people made important contributions to the Tyrannidae species accounts, although they were not actually authors of any full accounts. We are very grateful to Kristof Zyskowski, Isabelle Bisson, Greg Budney, Caroline Dingle, Van Remsen and Tom Schulenberg.

Once again, Robert Ridgely has most generously and efficiently revised all the maps affecting Neotropical species. Although this volume includes slightly fewer Neotropical species than the previous one, it still presented an enormous number to deal with over a relatively short period. Jeff Price has very kindly done the same job for the North American species, and in addition has checked and commented on the Status and Conservation sections of these same species. We offer our grateful thanks to both of them for their invaluable input.

We are extremely pleased to maintain our most useful agreement with VIREO at the Academy of Natural Sciences in Philadelphia (Doug Wechsler). Similarly, we are

very fortunate to be able to continue to enjoy the wealth of Guy Tudor's photo collection, which is of great help in many aspects of the work.

The French, German and Spanish names continue to come from the same sources as before, and we thank Normand David, Christoph Hinkelmann and Peter Barthel, and Eduardo de Juana, together with their respective associates, for their kind and efficient assistance throughout.

The individual authors and artists would like to offer their thanks to the following: Jan Andersson, Neil and Liz Baker, Richard Banks, Eustace Barnes, Keith Barnes, William Belton, Linda Birch, Isabelle Bisson, Paulette Bloomer, Wendy Borello, Charles Brown, Enrique Bucher, Greg Budney, Peter Capainolo, Stephen W. Cardiff, Geoff Carey, Vivianna Caro, Les Christidis, Rob Clay, M. Clout, Callan Cohen, Sarah Comer, Rene Corado, Phyllis Dague, Ann Danks, Pete Davidson, Richard Dean, E. C. Dickinson, Barny Dunning, Jessica R. Eberhard, Siegfried Eck, Victor Emanuel, Derek Engelbrecht, He Fen-qi, Lincoln Fishpool, Jon Fjeldså, Jeremy Flanagan, John Flynn, Edward Gavrilov, Alexander Gilmour, Alejandro Grajal, Richard Gregory, Mary Guthrie, M. Hansell, Jesús Herranz, Andrew Hester, Chris Hewson, Paul Holt, Ian Hood, Jesper Hornskov, Julian Hough, Álvaro Jaramillo, P. Jones, Guy Kirwan, Joris Komen, Niels Krabbe, Jeri Langham, Kathleen Langham, Wesley E. Lanyon, the late Richard Liversidge, Penn Lloyd, Florentino de Lope, Tim Lovegrove, Michael Magrath, Helen Marshall, G. R. Martin, Sjoerd Mayer, Juan Mazar Barnett, D. B. McDonald, Krister Mild, Jeremy Minns, Anders Møller, Coleen Moloney, Eugene Morton, D. Oschadleus, Robin Panza, V. Parker, Ricardo Parrini, Mark Pearman, Stephen Piper, Alan Poole, R. O. Prum, Robert Prys-Jones, Paulo C. Pulgarín-R., Keith Read, Van Remsen, Raleigh Robertson, C. Robson, Kees Roselaar, Philip D. Round, Patricia Ryan, Paul Salaman, Hans Schmid, Richard Schodde, Tom Schulenberg, Mary Sears, Chris Sharpe, Fred Sheldon, Ian Sinclair, Jacalyn Spoon, Claire Spottiswoode, Ali Stattersfield, Ian Stewart, Bridget Stutchbury, Tibor Szép, G. Tebb, Derek Thomas, P. W. Trail, Lindsay Tyler, L. Underhill, Gary Voelker, Barry Walker, B. A. Walther, Bret Whitney, Andrew Whittaker, David Willard, E. O. Willis, Mike Wilson, David Winkler, Jo Wrigley, Miguel Yanes and Kristof Zyskowski, and also the Ewell Sale Stewart Library at the Academy of Natural Sciences in Philadelphia, the American Museum of Natural History, the Australian National University, the Carnegie Museum of Natural History, the Cornell University Museum of Vertebrates, the Field Museum of Natural History in Chicago, Louisiana State Museum of Natural Science, Monash University, the Peabody Museum at Yale University, the Smithsonian Institution, the Museum of Victoria, and the Western Foundation of Vertebrate Zoology. Quico Suárez would like to present a special thank you to his recently departed mother, Antonia Cardona.

As ever, we would like to show our grateful appreciation for all the various different forms of help received from Mª Josep de Andrés, Rafa Armada, Raül Aymí, Adrián Azpiroz, Dolors Buxó, Juan Antonio Cantí, Cam Christie, Remko van Doorn, Fortunato Frías, Martin Goodey, Noelia Herranz, Anna Latorre, Michelle Le Marchant, Rosa Llinàs, Ferran López, Albert Martínez-Vilalta, Isabel Martínez, Rafael Martínez, Anna Motis, Eva Muñoz, Mary and Jim Ramsay, Olga Rius, Jorge Rodríguez Mata, Pedro Rubio, Kawai Sachiko, Aurea Vilalta and Nicole Wirtz. Toni Llobet has yet again provided us with the excellent illustration on the back cover, for which we thank him warmly.

Class AVES

Order PASSERIFORMES

Suborder TYRANNI

Family COTINGIDAE (COTINGAS)

- Very small to large arboreal birds, extremely varied both in form and in plumage, males of many species with brilliantly coloured or highly ornamental plumage; feed mostly, some species exclusively, on fruit.
- 7·5-51 cm.

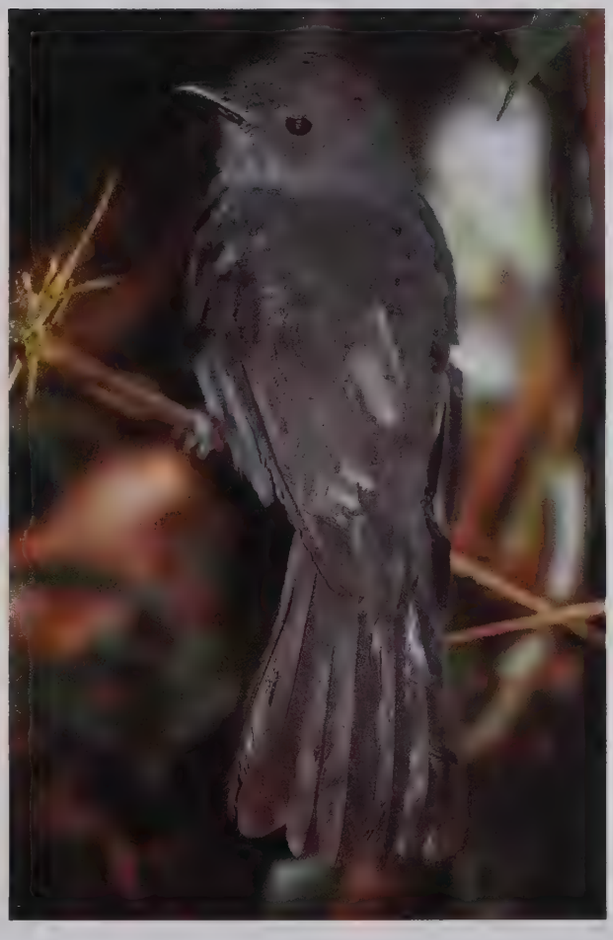
- Central and South America, including Trinidad.
- Mostly tropical and subtropical forest, a few species in temperate mountain woodlands.
- 29 genera, 71 species, 108 taxa.
- 16 species threatened; none extinct since 1600.

Systematics

There has for a long time been uncertainty about the composition of the family Cotingidae, as there has also been with the related families of the manakins (Pipridae) and the tyrant-flycatchers (Tyrannidae), and such uncertainty is likely to continue, at least in the near future. Following a number of nineteenth-century anatomical studies, these three families were distinguished from one another on the basis of the shape of the bill and the scutellation of the tarsus, as well as whether or not the toes were united and, if they were, to what extent. It soon became clear, however, that a classification based on these characters contained awkward exceptions. R. Ridgway, in his detailed systematic treatment of the Cotingidae in 1907, omitted bill shape, in particular, from the characters defining the family, as he considered it to be taxonomically uninformative at the family level. By the 1960s, further research into the structure of the skull and syrinx had demonstrated that changes needed to be made to what was then the traditional classification, the most important of these changes being the transfer to the Tyrannidae of several genera contemporarily included in the Cotingidae.

More recent research, with more genera available for study and supplemented by biochemical characters and DNA analyses, has indicated the need for further modifications. The two principal changes concern the three plantcutters (*Phytotoma*) and the monotypic genus *Oxyruncus*. The plantcutters are superficially very different from the "true" cotingas and were for long treated as constituting a small family of uncertain affinities, but it now seems well established that *Phytotoma* is, in fact, closely related, possibly as a sister-group, to a cotingid clade formed by the genera *Ampelion*, *Doliornis* and *Zaratornis*. As a consequence, it has become the standard practice in most recent handbooks for the genus *Phytotoma* to be placed in the Cotingidae. The peculiar and still little-known Sharpbill (*Oxyruncus cristatus*) is more problematic. The anatomical characters that have been studied do not provide clear evidence of its relationships, and the species' unique bill shape is considered phylogenetically uninformative. In some respects, such as the concealed crown patch and the male's modified outermost primary, the Sharpbill resembles the tyrannids, and certain other features, including the structure and musculature of the syrinx, support such a relationship. On the other hand, the general body proportions, the singing behaviour (see Breeding) and the fact that the young are fed by regurgitation point to a relationship with the cotingas. There has, however, been a reluctance to ally the species with the Cotingidae, as its tarsal scutellation is of the type known as exaspidean, which is not found among "definite" cotingids. Because of these conflicting data, the Sharpbill has commonly been placed in its own monotypic family. Nevertheless, DNA analysis suggests, rather surprisingly, an affinity with the cotingid genus *Pipreola*. For the time being, it is probably best to treat the Sharpbill as a cotinga, but the taxon clearly remains in need of further study.

As currently delineated, Cotingidae is made up of assorted genera, some of which are only dubiously included within its boundaries. The diversity of form, plumage and behaviour suggests that the family is a dumping ground for several unrelated lineages derived from tyrannoid ancestors. The ***Sharpbill*** *is a prime example. Long isolated in its own family, Oxyruncidae, it has many unusual features, not least its pointed bill. In its vocalizations and chick provisioning it resembles a cotinga, but its concealed crown patch, its modified first primary, and the structure of its syrinx all point to a link with the tyrant-flycatchers. The results of genetic analyses are inconclusive, so for the time being the Sharpbill is placed within Cotingidae, pending further research.*

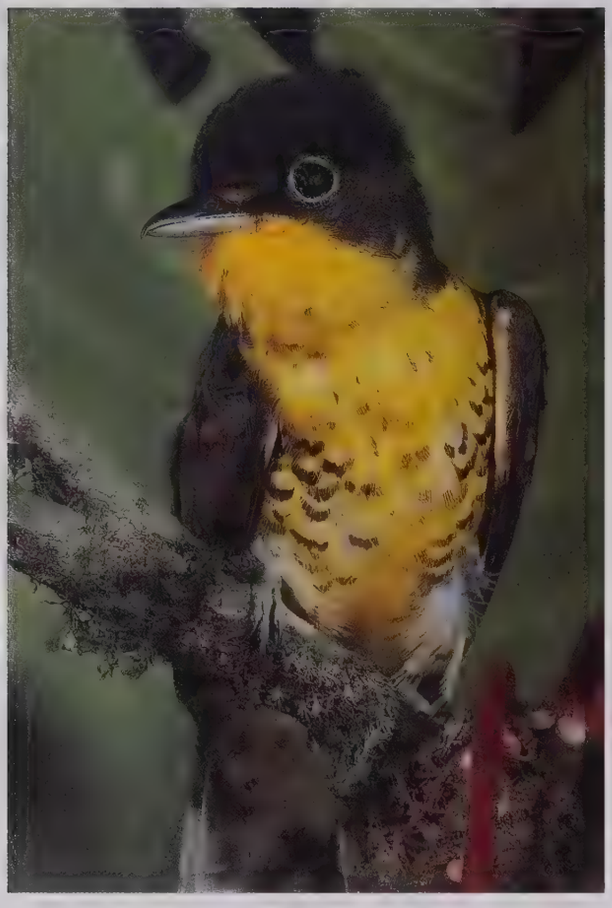


[*Oxyruncus cristatus cristatus*, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

Due to their anomalous morphology, the plantcutters were thought to justify a separate family, Phytotomidae. As new genetic data were analysed, however, it became clear that they were allied to a cotingid clade formed by three Andean genera, Ampelion, Doliornis *and* Zaratornis. *As such, the* ***White-tipped Plantcutter*** *and its congeners are now usually placed within Cotingidae. Their crests are unique in the family, and their distinctive rounded bills have fine serrations along the cutting edge, an adaptation for eating leaves and buds.*

[*Phytotoma rutila rutila*, Salinas Grandes, Argentina. Photo: Gabriel Rojo/ Nature Picture Library]

In its current constitution, the family Cotingidae contains a highly diverse array of genera, the relationships among which are far from clear. Although some authors have attempted to group the genera into several subfamilies, such treatment is considered unhelpful in that it appears to imply too definite a statement with regard to relationships. The sequence in which the genera are presented is, therefore, to a large extent arbitrary, and it is reasonable to suppose that future research will lead to substantial amendments. Indeed, some of the genera may be found to be sufficiently distinct that they merit elevation to family status. The sequence starts with two genera, *Oxyruncus* and *Phytotoma*, which are far from being typical of the family as a whole, and it ends with some of the most strikingly sexually dimorphic genera, which have developed to the highest degree the extravagant courtship and lek displays for which the family is best known. These last comprise the fruitcrows (*Haematoderus*, *Querula*, *Pyroderus*, *Cephalopterus*, *Perissocephalus*), for which there is good evidence that they form a natural group; the bellbirds (*Procnias*), which are almost certainly not closely related to the fruitcrows; and, finally, the red cotingas (*Phoenicircus*) and the cocks-of-the-rock (*Rupicola*), which, according to the findings of recent research, represent a monophyletic group, not closely related to either of the two preceding ones.



Future research is likely to result in major amendments to the sequence and content of the cotinga family, not least because new species are still being found. The ***Chestnut-capped Piha****, for example, was discovered in 1999 in the Central Andes of Colombia. It belongs to an Andean grouping which also includes the Dusky Piha* (Lipaugus fuscocinereus)*, and the Scimitar-winged Piha* (L. uropygialis)*, all three being relatively inconspicuous inhabitants of the dense cloudforest middle storey. Despite their retiring nature, they are all fairly large and distinctive. Indeed, the fact that such birds are still being unearthed from their remote Andean hideaways suggests that the South American continent still has more surprises in store.*

[*Lipaugus weberi*, Anorí, Antioquía, Colombia. Photo: Andrés M. Cuervo]

Within the family as presently recognized, most genera are extremely distinct. There are, in fact, only two areas of uncertainty. The first concerns the genera *Lipaugus* and *Tijuca*. The above-mentioned research, supported by DNA analysis, indicates that the inclusion of the Grey-tailed Piha (*Snowornis subalaris*) and the Olivaceous Piha (*Snowornis cryptolophus*) in the genus *Lipaugus*, as was the long-standing practice in all standard works, rendered that genus non-monophyletic; these two green-plumaged Andean species are only remotely related to the seven other, mainly grey-plumaged species, and they have recently been placed in a separate, newly erected genus, *Snowornis*. On the other hand, the Scimitar-winged Piha (*Lipaugus uropygialis*), restricted to the Andes of Bolivia and still poorly known, was for long placed in a monotypic genus, *Chirocylla*, a treatment based on its uniquely shaped flight-feathers. In other respects, however, it quite closely resembles two other grey-plumaged Andean species, the Dusky (*Lipaugus fuscocinereus*) and Chestnut-capped Pihas (*Lipaugus weberi*), notably in the modification of the barbs of the middle primaries (see Morphological Aspects), and it is probably more closely related to them than they are to the similarly grey-plumaged Amazonian and east Brazilian Screaming (*Lipaugus vociferans*) and Cinnamon-vented Pihas (*Lipaugus lanioides*). The general consensus among recent authorities in not recognizing *Chirocylla* seems preferable. This example has parallels in the cotingas' sister-family, the Pipridae, in which one species may exhibit strange and striking modifications of the wing or tail feathers that are not found in closely related congeners.

The affinities of the east Brazilian genus *Tijuca*, containing two species with very restricted ranges in the coastal mountains, are still uncertain. Analysis of feather proteins has suggested that the Black-and-gold Cotinga (*Tijuca atra*) and, less markedly, the

Grey-winged Cotinga (*Tijuca condita*) may be quite closely related to one of the *Lipaugus* species, the Screaming Piha, thus putting in doubt the validity of the taxon *Tijuca*.

The second uncertainty regarding generic limits involves *Ampelion*, *Doliornis* and *Zaratornis*. All are rather inactive fruit-eaters of the High Andes, lacking brilliant colours, and possessing a semi-concealed reddish nuchal crest, although this is reduced to a vestigial patch in *Zaratornis*. *Doliornis* has a narrower and less hooked bill than that of *Ampelion*, and differs markedly in its juvenile plumage. *Zaratornis* is the most distinct in plumage, and it differs from *Ampelion* in some details of skull structure. Whether these differences outweigh the similarities and warrant generic status is a matter of largely subjective judgment, and there is disagreement among taxonomists. The most recent opinion is that *Doliornis* and *Zaratornis* merit recognition, and this treatment is therefore maintained, although with reservations.

Whatever the eventual taxonomic treatment of these problematic cases, it is unquestionable that the cotingas, as now recognized, are among the most diverse of passerine families. Indeed, they are perhaps the most diverse of all. They exhibit the widest size range, from the tiny Kinglet Calyptura (*Calyptura cristata*) up to the big, heavy umbrellabirds (*Cephalopterus*), the latter being as large as a crow (Corvidae), and they display an extraordinary diversity of form and of plumage. Thirteen of the 29 genera are monotypic, and six or seven others consist of single "zoogeographical species", defined as closely related forms which replace one another geographically, with no, or minimal, distributional overlap. Furthermore, only in the cases of *Pipreola* and *Cotinga* do two or more congeners regularly occur together in the same area. The diversity of the genera is, indeed, so great that one is forced to wonder whether what is now treated as a family actually consists of a number of lineages that arose independently from the tyrannoid stock at a very early stage of its radiation. If this is so, future research may lead to a classification radically different from that currently adopted.

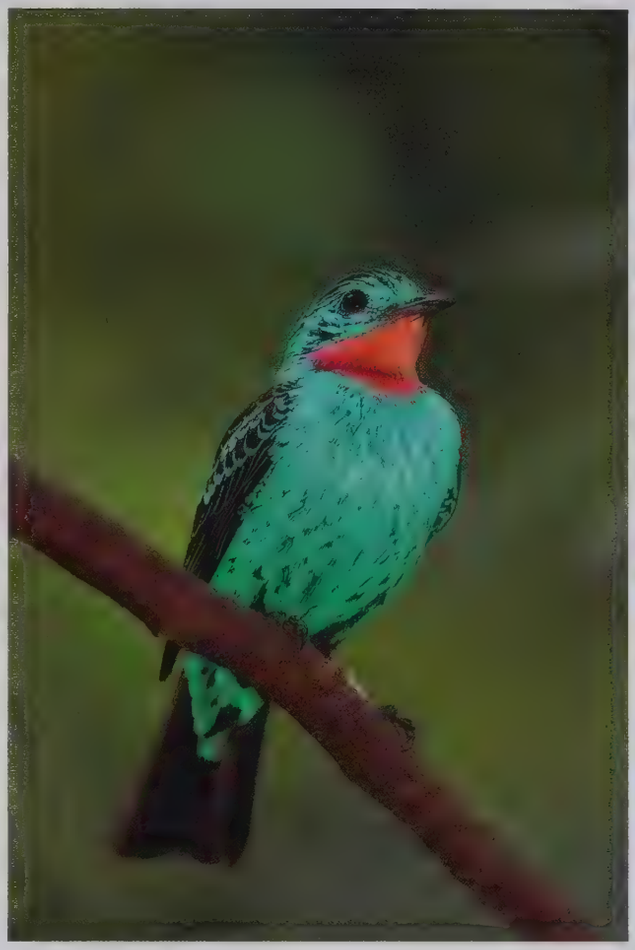
If the classification of the cotingas at the higher levels remains controversial, at the level of the species there is very general agreement. Some recent authorities have split the Elegant Mourner (*Laniisoma elegans*) into two species, but the two forms, one comprising the nominate race in south-east Brazil and the second consisting of three other subspecies in the Andes, differ rather slightly; both remain little known. A similar instance involves the Swallow-tailed Cotinga (*Phibalura flavirostris*), the recently rediscovered Bolivian subspecies of which differs in a number of characters from the geographically remote nominate race of south-east Brazil and adjacent Paraguay and Argentina. Both cases have consequences affecting conservation priorities (see Status and Conservation).

Morphological Aspects

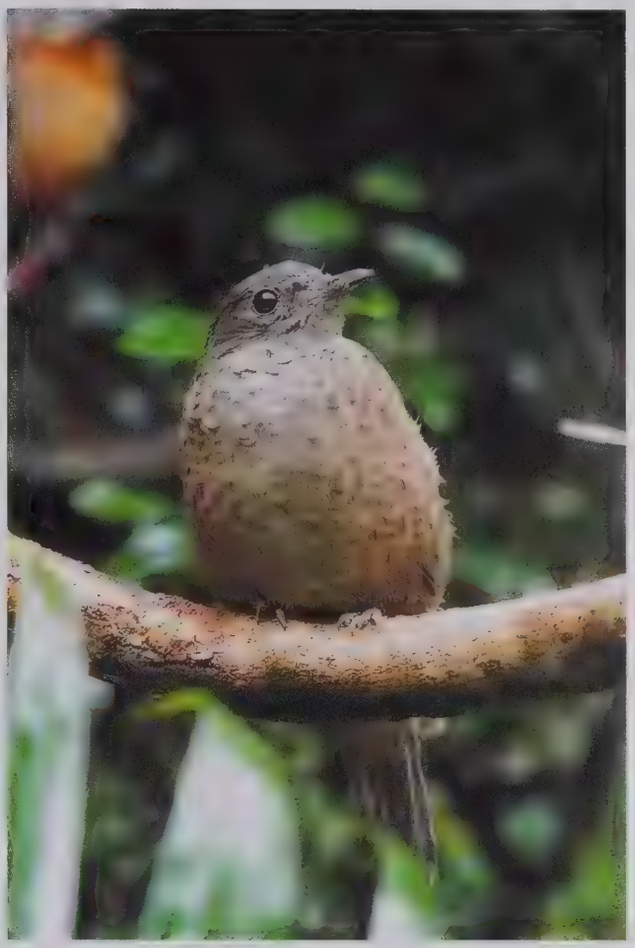
The extreme diversity of the cotingas has already been stressed (see Systematics). They have the widest size range of all passerine families, the largest species being about 80 times as heavy as the smallest and about six times as large, as measured by both wing length and total length. Thus, the diminutive Kinglet Calyptura, no bigger than 8 cm and, as its vernacular name implies, reminiscent in size and plumage of a kinglet of the mainly Holarctic genus *Regulus*, is dwarfed by the male Amazonian Umbrellabird (*Cephalopterus ornatus*), which, at about 50 cm in length and probably half a kilogram in weight, is the largest Neotropical passerine. The cotingas also vary greatly in body proportions and in bill size and structure, although none has the typical wide, flat bill, with well-developed rictal bristles, that is the main type of bill among the related tyrant-flycatchers. Finally, they vary spectacularly in plumage colour and ornamentation.

Structurally, bill size and shape are most conspicuously diverse. Leaving aside the Sharpbill and the plantcutters, the bills of which are of unique form, three main bill types can be distinguished. Small to medium-sized cotingas, with a main diet of small fruits, tend to have a short bill, moderately hooked at the tip and with a slightly arched culmen; examples are the berryeaters and fruiteaters of the genera *Carpornis* and *Pipreola*. Some of the larger and more specialized frugivores, adapted to feeding on relatively large fruits which, as with all cotingas, they swallow whole, have a short bill, very wide at the gape, as seen in extreme form in the bellbirds (*Procnias*) and in less extreme form in the white-winged cotingas (*Xipholena*). In contrast, the very large cotingas, with diets consisting mainly of large fruits and large insects, have a long, strong, crow-like bill, from which they have long been known as fruitcrows.

The Sharpbill is named after its highly distinctive bill. This is very sharply pointed, with a broader base, and is used as a wedge to pry open rolled leaves in order to extract concealed prey and, similarly, to open dehiscing fruit so as to extract seeds. At the opposite extreme, the plantcutters possess a short, stout,



Previously called the Shrike-like Cotinga, the ***Elegant Mourner*** *looks nothing like a shrike, and is quite possibly not a cotinga. Genetic analysis is inconclusive, but suggests links with genera currently treated as piprid, such as* Schiffornis, *or tyrannid, for example* Laniocera. *It is retained in its traditional position, pending further review. Regardless of ancestry, it provides a good example of fluctuations in species-level taxonomy, and the impact this has on conservation priorities. Some authors consider the nominate race to be a separate species, in which case it is classed as Vulnerable, and thus qualifies for conservation funding. If lumped with the Andean races, however, as here, the entire complex is not reckoned to require red-listing at present.*



[*Laniisoma elegans buckleyi*,

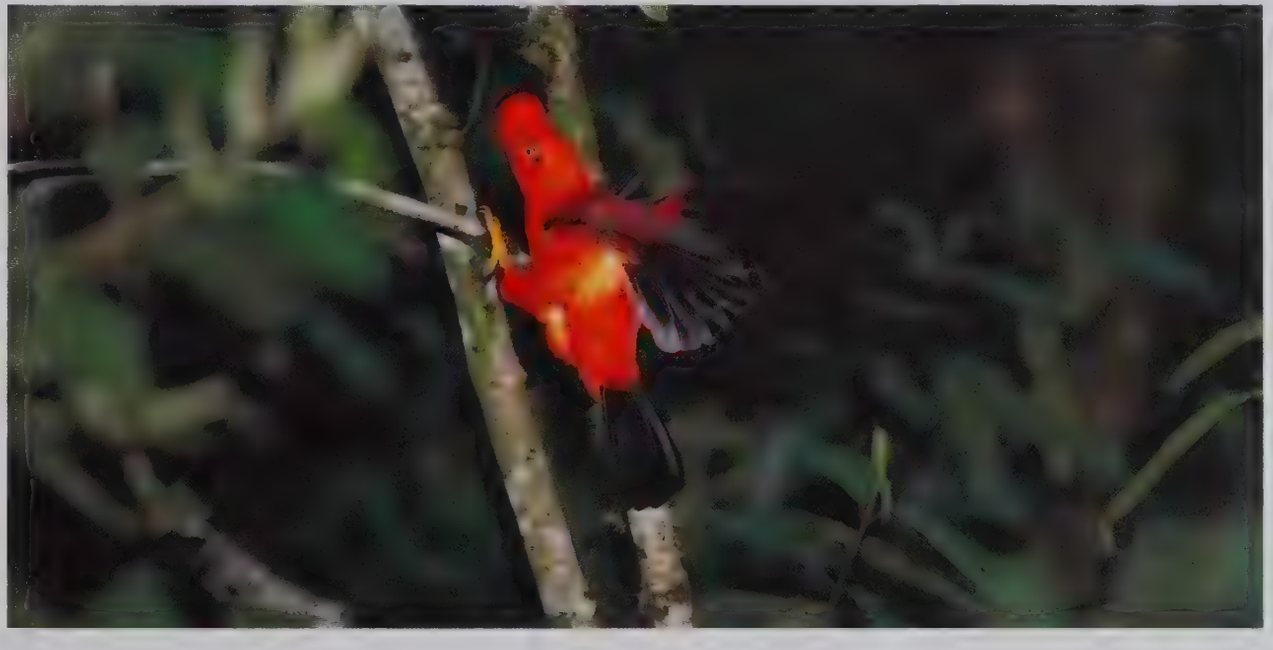
Until the early 1990s, the ***Chestnut-bellied Cotinga*** *went unnoticed in the highlands of Ecuador, where it is quite widespread but very thinly and patchily distributed. It is a member of a trio of genera, including* Zaratornis *and* Ampelion, *restricted to cloudforest or* Polylepis *forests in the high Andes. There are distinct differences between these genera, but also overlaps in voice, morphology and behaviour. Further research might lead to a merger into a single genus.*

[*Doliornis remseni*,
Ecuador.
Photo: Mark Robbins/
VIREO]



It is difficult to make any sweeping statements about cotingid morphology, so variable are the different genera. Their bills are comparatively diverse, in size and shape, ranging from very short and wide to long, powerful and crow-like. Strong sexual dimorphism is a common theme in many genera, as demonstrated by these ***Spangled Cotingas****, medium-sized members of the family, with rather short, moderately wide bills. Males tend to be flamboyantly colourful, while females are often dull, sometimes with a scaled effect. In cotingids, and passerines in general, the males are usually the larger sex, but in a few species, for reasons as yet unknown, females are slightly larger.*

conical bill with finely serrated edges, well suited to their herbivorous diet.

There is a good deal of variation in wing and tail lengths in relation to overall size, in most cases clearly associated with general mode of life and feeding method. Thus, the three purpletufts (*Iodopleura*), which feed largely, and for cotingids atypically, by hawking for flying insects from treetops, are very long-winged for their weight. The Purple-throated Fruitcrow (*Querula purpurata*), too, has relatively long wings, but they are also broad. Its conspicuous agility in flight, doubtless dependent on these wing proportions, appears to be an important adaptive character in its unique social organization (see Breeding). Of the species that are relatively short-winged, the two red cotingas (*Phoenicircus*) and the Scaled Fruiteater (*Ampelioides tschudii*) stand out: the former are rather manakin-like in their courtship behaviour and in keeping to the lower forest strata; and the latter is unusual in that it forages by working along more or less horizontal tree branches, rather than by the normal cotingid technique of taking fruit and insects in aerial sallies (see Food and Feeding). The only cotinga with a very long, forked tail, the Swallow-tailed Cotinga, is, like the purpletufts, unusual in its habit of hawking for flying insects, and it is also the most aerial of all the members of the family in its general behaviour.

Cotingas have short legs and, in common with other passerines, their toes are arranged three forwards, one back. This design allows bulky birds, such as the ***Andean Cock-of-the-rock****, a strong grip on a variety of perches. In many species the flight-feathers are curiously modified. The Andean Cock-of-the-rock's slender outer primary is visible in this photograph.*

Elegem]

*The **Plum-throated Cotinga** belongs to the genus* Cotinga*, from which the family draws its common and scientific names. This is a group of treetop species, which generally keep to the forest canopy. They are usually termed the "blue cotingas", for obvious reasons! The vivid cast of the male's plumage is famous, but his modified primaries are less well known. In this species, the inner webs of the outermost primaries (7-10) are sinuated, and the eighth primary is very slender. In ordinary flight these feathers produce a strange tittering or rattling sound, which is accentuated during display.*

[*Cotinga maynana*, River Napo, Ecuador. Photo: Hans D. Dossenbach]

Curious and striking specializations in the structure of the flight-feathers are a feature of several cotingid genera. In all cases they are fully developed only in adult males, being less pronounced or absent in females and young birds; hence, they almost certainly have some function in male courtship display, but the details of this are still little understood. In the seven species of *Cotinga*, the blue cotingas, adult males in flight make a rattling or tittering sound, undoubtedly produced by the modified outer primaries, but the modifications are conspicuously and puzzlingly different in each species, involving variation in length of the feathers, attenuation to various degrees of the feather tips, and narrowing of the central part of the vane. For example, the adult male Turquoise Cotinga (*Cotinga ridgwayi*) has primaries 9 and 10 thin and short, P9 especially so, and somewhat incurved at the tip, and the outer webs of both P8 and P9 are sinuated near the base; in the male Plum-throated Cotinga (*Cotinga maynana*), however, it is the inner webs of primaries 7-10 that are sinuated, and P8 is very slender. The adult male Spangled Cotinga (*Cotinga cayana*) has primaries 9 and 10 thin and tapering, and slightly recurved, while the outer webs of primaries 6 and 7 have non-interlocking barbs which form a fringe; in addition, the inner secondaries are very long. The two most curious modifications are found in the *Phoenicircus* red cotingas and in the Scimitar-winged Piha. In the former, primary 7 is uniquely modified, being very short and twisted, while in the latter all primaries except the innermost are outwardly curved, pointed, and shortened to different degrees, with P5-8 each progressively shorter than the preceding one, and P9 and P10 much longer. Other genera in which the males exhibit modifications of the flight-feathers to a greater or lesser extent include *Oxyruncus*, *Laniisoma*, *Xipholena*, *Procnias* and *Rupicola*.

The genus Xipholena *is related to* Cotinga*, and likewise contains a set of richly coloured medium-sized canopy species (this **Pompadour Cotinga** has been photographed outside its normal habitat). The dominant colour in the plumage of males is purple, and the group is often referred to as the "purple cotingas". In two species of the trio, the lengthened covert plumes drape luxuriously, offset by the whiteness of the wings. The latter feature is especially conspicuous in flight or during displays. The Pompadour Cotinga is a widespread bird in Amazonia, but it is somewhat tied to lower-stature woodland, especially where this is on sandy soil.*

[*Xipholena punicea*, Venezuela. Photo: Roland Seitre]

Sexual size dimorphism among the cotingas is much as that found in other passerine families. Males are somewhat larger than females, the latter's wing length averaging 93-99% of that of males. Considerably greater differences exist among the umbrellabirds and the bellbirds, the females of which have average wing lengths that are, respectively, 84-89% and 85-89% of those of the males. These are birds with highly developed male ornamentation associated with striking courtship displays (see Breeding); probably in all of them, dominant males defend traditional display and mating perches against other males, so that there may be a strong selective advantage in large size.

In a few genera and species of cotinga, females are slightly larger than males. This is the case with at least one of the blue cotingas, with the Purple-throated Cotinga (*Porphyrolaema porphyrolaema*) and, probably, with the red cotingas. No plausible explanation for this can be suggested, except in the case of

The fruiteaters (Pipreola) *make up the most species-rich genus in the family. Of 11 species, 10 are morphologically homogeneous Andean birds, and one is a divergent form restricted to the tepuis of southern Venezuela. Distinctively, the bills are red or reddish. In terms of plumage, green and yellow are the dominant colours, although males often have black on the head and chest, and red or orange on the throat or breast. Females are much duller. The* ***Green-and-black Fruiteater*** *is the most widespread and numerous member of the genus. It is fairly common in the understorey and subcanopy of moderate-altitude Andean forests from Venezuela to Peru.*

[*Pipreola riefferii occidentalis*, La Planada, Colombia. Photo: Luis Mazariegos]

the red cotingas, whose courtship display is reminiscent of that of some of the manakins, with males engaging in very active and agile flight manoeuvres in the lower forest strata. The blue cotingas are especially puzzling. Females of the Plum-throated Cotinga are on average larger than the males in all measurements, and those of the Turquoise Cotinga exceed the males in most measurements and are considerably heavier; in the Purple-breasted Cotinga (*Cotinga cotinga*) and the Banded Cotinga (*Cotinga maculata*), on the other hand, males are distinctly larger than females. In the three other species of blue cotinga, the males are slightly the larger sex.

Many cotingas exhibit striking differences between the sexes in adult plumage, the males being conspicuously brighter in coloration or having remarkable adornments. Indeed, among passerine birds, only the birds-of-paradise (Paradisaeidae) exceed them in the brilliance and extravagance of the males' plumage. In some cotingids, on the other hand, male and female plumages differ only slightly or not at all. As described later (see Breeding), the male ornamentation is associated with conspicuous, and in many instances quite amazing, displays. In several cases, however, what seem to be equally striking displays are performed by males of species with almost no sexual dimorphism, the Screaming Piha, the Capuchinbird (*Perissocephalus tricolor*) and the Red-ruffed Fruitcrow (*Pyroderus scutatus*) being three such examples.

In the *Cephalopterus* umbrellabirds and the *Procnias* bellbirds, two genera of large or medium-large cotingids, the adult males have the head or neck adorned with wattles or brightly coloured bare skin. The wattles are conspicuously exhibited in display, in two radically different ways. In the case of the umbrellabirds, they are inflated with air. In the White Bellbird (*Procnias albus*), the only one of the three wattle-bearing species of *Procnias* that has so far been studied anatomically, the single wattle is richly vascularized; during display it is extended, rather slowly, apparently by engorgement of the blood vessels, and contracted, more rapidly, probably by emptying of the blood vessels and contraction of longitudinal muscle fibres.

Brilliant plumage is a feature of the adult males of many cotingas. As with the great majority of other birds, carotenoid pigments are responsible for red, orange and yellow colours, while blue is produced by structural modification of the feathers, greens being produced by a combination of pigment and structure. Although birds cannot synthesize carotenoid pigments but, rather, are dependent for them on their diet, fruit in the cotingas' case, they can modify the chemical structure of the pigments once these have been assimilated. In the white-winged cotingas in the genus *Xipholena*, the production of very intense, glossy reds and purples is due to a dark form of red carotenoid pigment combined with structural blue, and modification of the feather structure, the barbs being flattened and lacking barbules.

Habitat

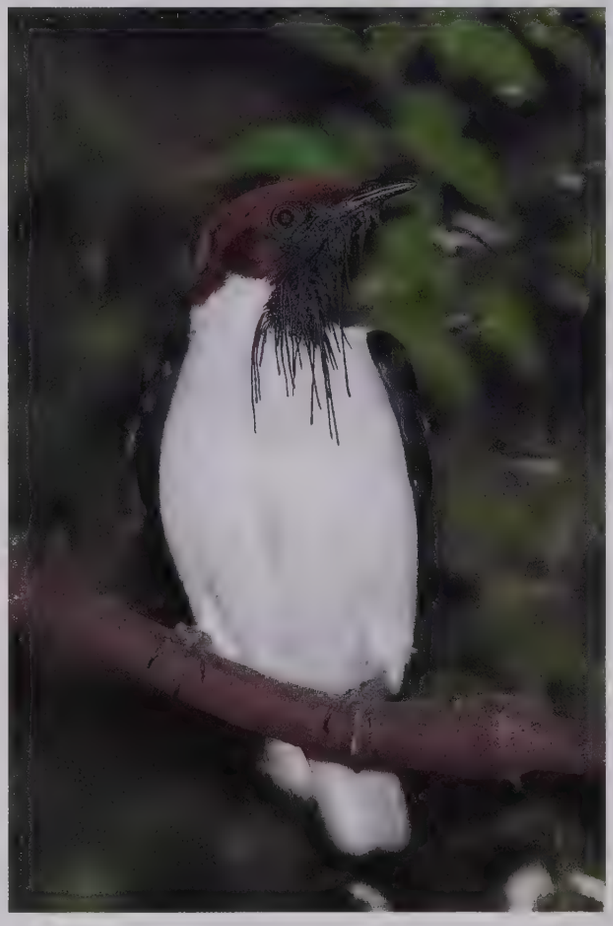
"Humid forest" is a very broad, but accurate, description of the habitat of nearly all members of the family. The species vary greatly, however, in the altitudinal range which they occupy, from tropical lowland forest to high-altitude temperate forest, and in the strata of the forest which they mainly inhabit and utilize for their different activities. Most cotingids occur in lowland forest, and smaller numbers at higher elevations. Thus, up to nine or ten different species may live together in the same general area in Amazonian forest, and up to five or six species may do so in subtropical Andean forest. A few species, in the related genera *Ampelion*, *Doliornis* and *Zaratornis*, live even higher in the Andes, culminating in the very local White-cheeked Cotinga (*Zaratornis stresemanni*), a globally threatened cotingid which

The genus Lipaugus *contains seven species, all of them rather modest in pattern and colour. As a rule, they perch lethargically in the middle storey and would be difficult to find were it not for their loud vocalizations. Two montane taxa were recently removed from* Lipaugus, *and placed in a new genus,* Snowornis. *Interestingly, the Screaming Piha* (Lipaugus vociferans) *of Amazonia is grey, as are two Amazonian mourners of the genera* Laniocera *and* Rhytipterna. *On the other side of the Andes, all three representatives of these genera are rufous, including the* ***Rufous Piha****. Some form of mimicry may be in operation, but how or why remains mysterious.*

[*Lipaugus unirufus castaneotinctus*, Ecuador.
Photo: Doug Wechsler/ VIREO]

is restricted to stunted tree-line forest at up to 4250 m in a small area of Peru. The only species which do not, on a broad definition, qualify as forest birds are the plantcutters, which inhabit open scrub and open woodland, including farmland, and the Swallow-tailed Cotinga of eastern Brazil, which frequents forest edges, semi-open country, and even gardens. Perhaps the most divergent is the Peruvian Plantcutter (*Phytotoma raimondii*), an Endangered species of coastal north-west Peru, which is found in sparse desert scrub and barren coastal dunes, with openly dispersed large bushes, from sea-level up to 550 m.

A few species are found, at least in some areas, mainly or entirely in certain types of lowland forest. Most notably, the Amazonian Umbrellabird, over much of its range, is rather strictly associated with forested river islands and swampy areas along the banks of the larger rivers, although in the far west of the Amazon Basin it occurs in hilly forest along the base of the Andes. The Bare-necked Fruitcrow (*Gymnoderus foetidus*) is also found mainly along the forested shores of rivers and lakes, while the very local Black-faced Cotinga (*Conioptilon mcilhennyi*), known only from a limited area of east Peru and adjacent west Brazil and Bolivia, favours swampy and seasonally inundated forest. In Central America, the Yellow-billed Cotinga (*Carpodectes antoniae*) occurs mainly in coastal mangroves, but also in adjacent mixed forest. It seems likely that, in such cases, habitat choice is at least in part dictated by the availability of certain preferred fruits, but this aspect has not been adequately studied.



Food and foraging habits, courtship behaviour and, in a few instances, nesting requirements clearly influence habitat choice on a local scale and preferences for different forest strata. Male Bearded Bellbirds (*Procnias averano*), for example, favour high calling posts situated on ridges or slight promontories on the sides of valleys, from which the surrounding slopes can be overlooked, while the forest immediately below a calling post must contain small trees suitable for the later stages of courtship (see Breeding). The two *Rupicola* species have the habit, unique within the family, of attaching the nest to a rock face, and this is the major influence on their choice of habitat. Thus, the Andean Cock-of-the-rock (*Rupicola peruvianus*) is confined to forest along or close to rocky gorges of mountain rivers and streams, and the Guianan Cock-of-the-rock (*Rupicola rupicola*) is restricted to forest in the vicinity of weathered rocky outcrops and caves.

With the exception of those of the cocks-of-the-rock, few cotingid nests have been found. The small number that have been located (see Breeding) indicate that the nests are often sited in isolated trees in more or less open areas adjacent to forest, rather than within closed forest, or, if within forest, in trees standing clear of the surrounding vegetation. This was so, for instance, for the only recorded nests of the Turquoise Cotinga and the Lovely Cotinga (*Cotinga amabilis*), and for all recorded nests of the Bearded Bellbird. For these and probably other cotinga species, therefore, the nesting habitat, on a local scale, is different from the main foraging habitat. Any explanation for this must be tentative, as facts are few, but it seems likely that the choice of isolated trees for nest-sites is an adaptation designed to reduce the risk of predation by arboreal mammals. In the only detailed study of the nesting of the Purple-throated Fruitcrow, it was noted that, when a troupe of capuchin monkeys (*Cebus capucinus*) passed through trees close to the nest, they did not disturb the nest tree, which was in a rather open area of forest and not in contact with the surrounding trees.

An unusual, if minor, aspect of the habitat of the Guianan Cock-of-the-rock is that, locally, the birds themselves may to some extent create their own habitat. Thus, a study of the vegetation of a lek area (see Breeding) in French Guiana showed that the majority of the trees had probably grown from seeds regurgitated or defecated over the years by the displaying males.

General Habits

Thirty-five years ago, A. F. Skutch, at that time by far the most experienced observer of Neotropical birds, wrote of the cotingas as follows. "The cotingas known to me are all birds of the tree-tops.... Some of the species which inhabit the lofty rain forest stay so consistently in the high upper regions inaccessible to man, that one may hear their cries day after day yet hardly ever glimpse the birds themselves. No other family of birds of the Western Hemisphere presents such great obstacles to study; in no other are nests

The bellbirds form a well defined quartet of large, canopy-dwelling cotingas. They are characterized by wholly or largely white plumage, loud chiming or clanging vocalizations and marked sexual dimorphism. They have very wide gapes designed for swallowing large fruit. In particular, they are famed for the bizarre adornments on the heads of the males. The male ***Bearded Bellbird****, for example, has a throat entirely covered in fine wattles. Like his congeners, in the breeding season he calls incessantly from a high, treetop perch. When a female has been attracted, he descends to a low perch in the understorey for the next stage in his pre-mating display.*

[*Procnias averano*, Brazil.
Photo: Roland Seitre]

There is some disagreement as to the correct taxonomic placement of the purpletufts. According to one analysis of morphological features, they belong to an assemblage made up of Laniisoma, Schiffornis, Pachyramphus, Laniocera *and* Xenopsaris *–a motley combination of supposedly tyrannid, piprid and cotingid genera. As no conclusive evidence is forthcoming,* Iodopleura *is retained for the time being in Cotingidae. The purpletufts are the smallest members of the family, and they have by far the longest wings for their weight. Their long primary feathers, easily visible on this* ***Buff-throated Purpletuft****, are directly related to an aerial foraging strategy. They sally for flying insects above the canopy, like miniature Swallow-winged Puffbirds* (Chelidoptera tenebrosa). *Consequently, purpletufts are best found by scanning bare branches protruding from the canopy, or by looking for pairs or small family groups perched high in dead trees. They are by no means solely insectivorous; they also pluck berries from trees, creepers and saplings, often descending to lower growth at forest edges. Their English name derives from the silky tuft at the bend of the wing. Often invisible, this feature is flared prominently during display.*

[*Iodopleura pipra leucopygia*, Boa Nova, Bahia, Brazil. Photo: Edson Endrigo]

Few birds are decked out more strangely than umbrellabirds. The largest passerines in the Americas, they wear a preposterous dangling appendage from the chest, and the bill is shaded by a parasol. When perched and not displaying, the wattle is short, the crest withdrawn, and they look like quiffed crows. On the wing they seem more like giant stumpy woodpeckers with heavy, undulating flight. But when they display, there can be few more eerie or impressive sights than ***Long-wattled Umbrellabirds*** *in heavily forested hills of the Chocó. Silhouetted, with wattles inflated and vastly extended, small groups of males gather on mossy boughs, booming like fog-horns in the misty woods.*

[*Cephalopterus penduliger*, Ecuador.
Photo: Roland Seitre]

more difficult to find, or so hard to reach if they have been located. Yet no family of birds, not even excluding the birds-of-paradise, so excites the wonder and curiosity of the naturalist, so challenges him to pry into the well-guarded secrets of their lives."

Since Skutch wrote those words, in 1969, much more has been discovered with regard to the small number of species that have proved most amenable to study, but a great deal still remains unknown. Little or nothing is known about the behaviour and social organization of many of the Cotingidae. The obvious diversity of their social behaviour has stimulated some detailed research, but this has been mainly confined to the small number of species that perform spectacular courtship displays in groups, generally known as leks (see Breeding).

Few generalizations can be made, but one that seems valid for the family as a whole is that cotingas tend to remain inactive for long periods, almost certainly as a consequence of their predominantly frugivorous diet, which usually allows them to devote a very small part of the day to foraging. Adult males that hold a display area will be present at it for the greater part of the daylight hours. Thus, a male Bearded Bellbird, watched continu-

The genus Ampelion *contains two species, both adapted to life in Andean cloudforests. Both have bright red eyes, and a conspicuous nuchal crest, which can be flared during aggressive interactions or displays. Their "song" is a strange nasal reeling or buzzing note, reminiscent of that of plantcutters* (Phytotoma). *By far the commoner of this duo is the* ***Red-crested Cotinga****, captured here in characteristic pose, perching prominently above cloudforest trees and shrubs.*

[*Ampelion rubrocristatus*, San Miguel, Cochabamba, Bolivia.
Photo: Johannes Ferdinand]

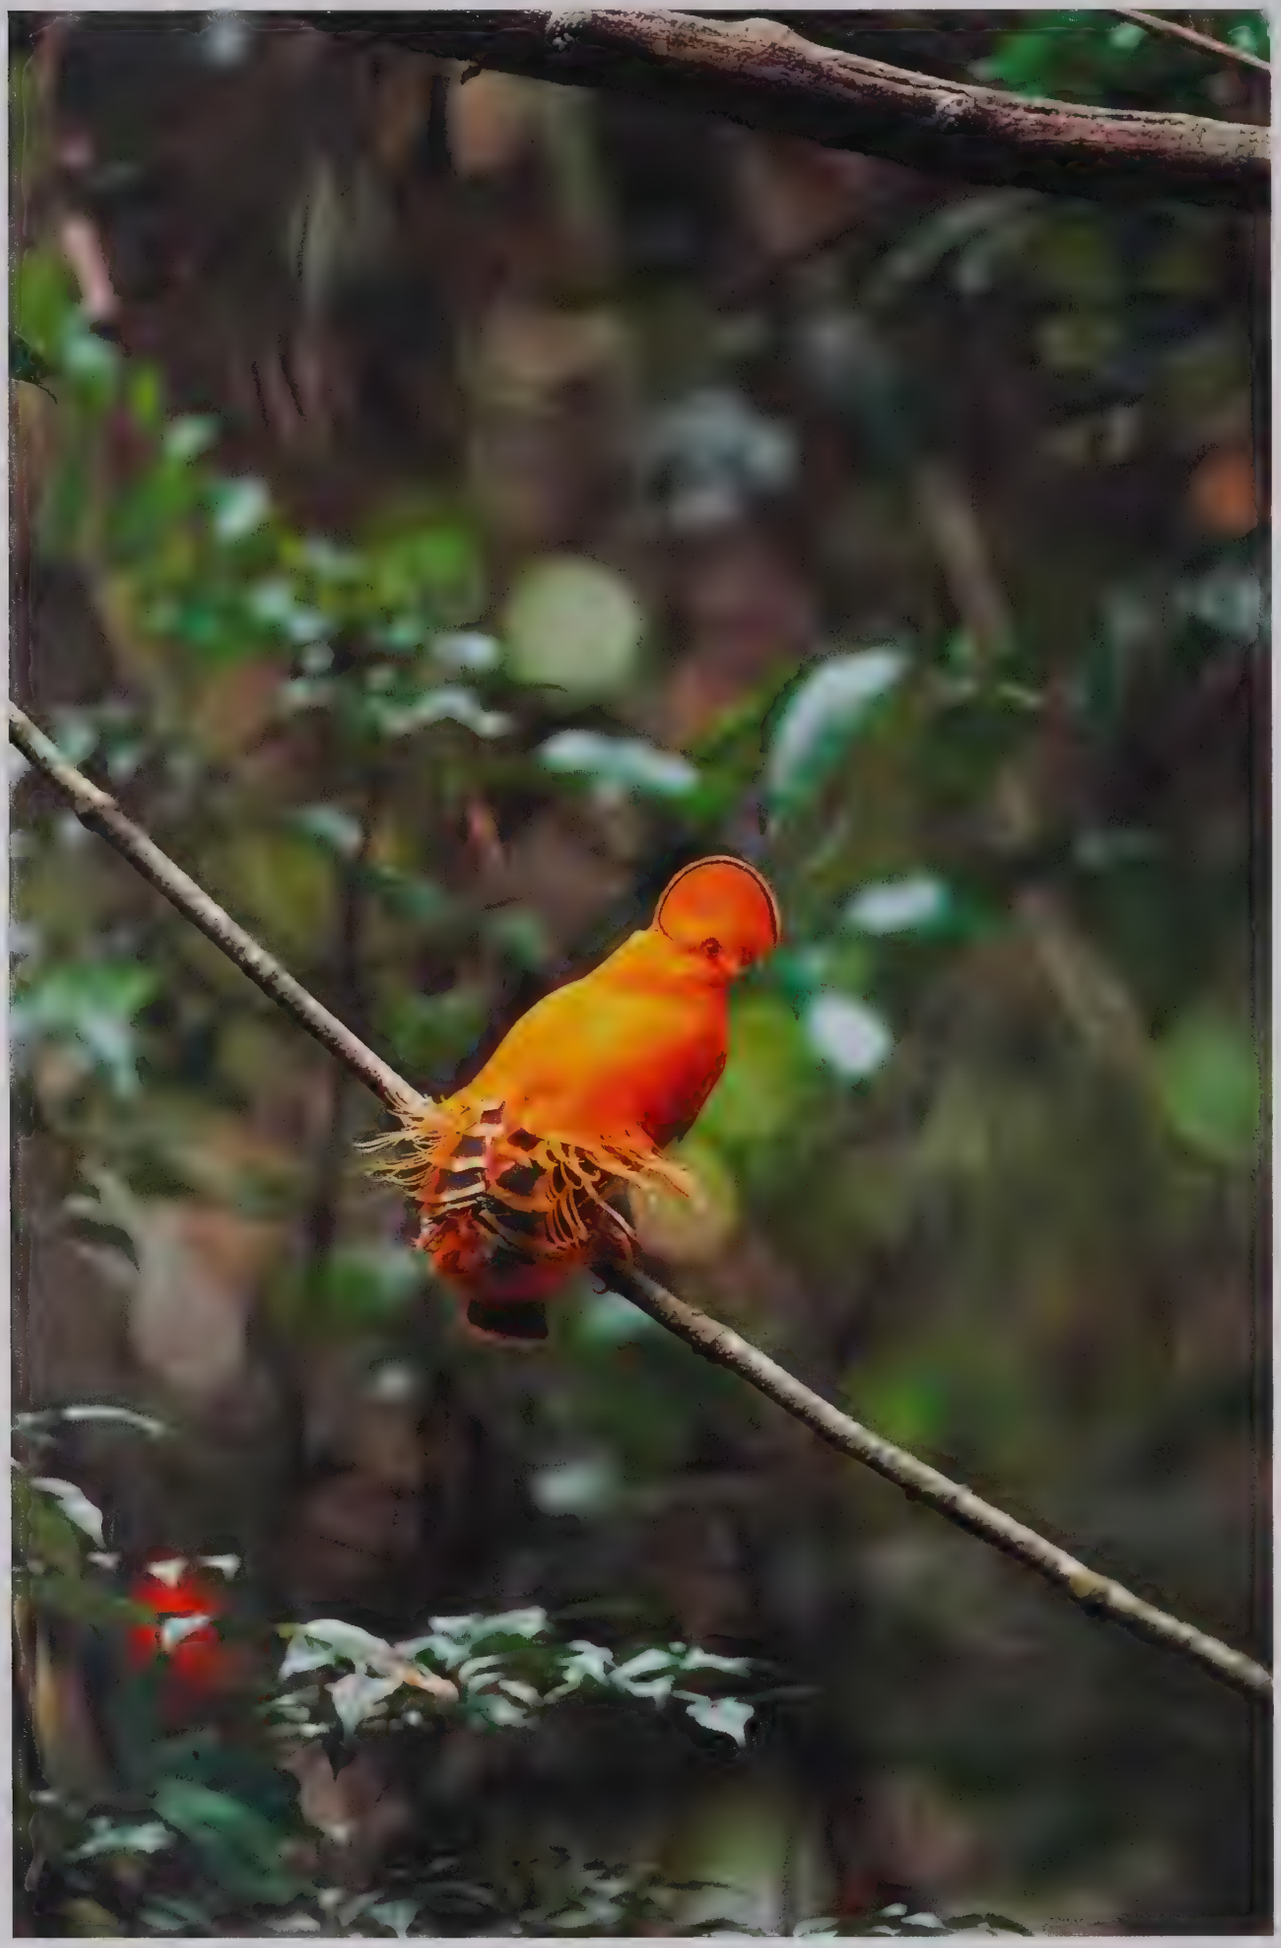
Two strikingly patterned species endemic to the Atlantic Forest of south-east Brazil are known as berryeaters (Carpornis). *The* ***Hooded Berryeater*** *is the commoner, especially at medium elevations in the Serra do Mar. Both species are black on the head, and otherwise mainly olive or yellow. In the colour and pattern of their plumage they are reminiscent of Old World orioles (Oriolidae) or overgrown finches, but their shape and behaviour is distinctly cotingid. Both produce powerful and distinctive songs at regular intervals. They are generally inconspicuous, and were it not for these vocalizations they would be difficult to find.*

[*Carpornis cucullata*, São Miguel Arcanjo, São Paulo, Brazil. Photo: Edson Endrigo]

ously from dawn to dusk, was present in his calling territory for 87% of that period, mainly inactive but calling for 74% of the time during which he was present. The tendency of many cotingids to remain inactive for long periods, whether calling or not, in treetops has made them very difficult to study, as Skutch mentioned, but in recent years observation from canopy-level towers has provided new opportunities for observing some aspects of their behaviour, including spectacular displays never before witnessed by ornithologists. One further generalization that may be made is that, with very few exceptions, notably the Bare-necked Fruitcrow and the plantcutters, cotingids do not form flocks, although several species gather temporarily in small groups at fruiting trees. Individuals of some of the Andean species, however, regularly accompany mixed-species foraging groups.

According to the limited knowledge currently available, the social organization of the cotingids is diverse. Adults of a few species apparently live in conventional pairs, and both sexes attend the nest. This is the case with, in particular, the fruiteaters in the largely Andean genus *Pipreola*, the *Iodopleura* purpletufts, the Black-faced Cotinga and the plantcutters. Some members of the family do not form pairs; the males are polygamous and do not attend the nest. For many others, the mating system is still unknown. The Purple-throated Fruitcrow, however, has a social organization that is quite different from that known for any other cotingid, and reminiscent rather of that of some New World jays (Corvidae). It is highly social, living in small groups of 3-8 individuals which not only move around, forage and roost together, but also jointly attend a single nest. The Purple-throated Fruitcrow is fairly large and, for a cotinga, long-winged and highly agile in flight, and the whole group takes part in defence of the nest.

Various studies and observations have shed light on the displays of some of the Cotingidae, which in many cases exhibit a number of intriguing and, occasionally, unique features. These are discussed later (see Breeding).



Voice

In voice, as in other respects, Cotingidae is a family of extremes. Male bellbirds make what are probably the loudest of all bird calls, whereas some other species seem to be completely voiceless as they have never been heard to utter any calls. In common with those of the other families of the suboscine passerines, the vocalizations of cotingids are comparatively simple, lacking the complex structure and generally without the musical quality of the songs of the oscines, or "true" songbirds. Most of their calls, and all of the loudest and most striking ones, are associated with the males' displays (see Breeding).

Despite the vernacular name of the genus, only one of the bellbirds, the White Bellbird, has a call that is bell-like. The vocalizations of the other three species are more akin to the sound of a hammer striking an anvil or a hard wooden block. So far-carrying are their calls, across the forested hills and valleys where they have their display grounds, that the birds are heard much more often than they are seen. Each of the species has a distinct repertoire, consisting of a single very loud "bock" or, in the case of the White Bellbird, a double "ding ding", and a succession of one or more kinds of less loud calls. It is worth mentioning a few of the curious or interesting points connected with these birds' extraordinary voices.

A young male Bearded Bellbird, colour-ringed as a nestling, began to practise its calls when it was about 15 months old. Initially, and as with other young bellbirds that have been watched, it was able to make only harsh squawks. After five months of practice the harsh squawk had developed into the adult "bock", but after seven months of further practice the bellbird still had not perfected the repeated call, a less loud "tonk-tonk-tonk...". Similarly, a young male Bare-throated Bellbird (*Procnias nudicollis*), housed in a zoo next to an adult male that called regularly, had not perfected its repeated call after ten months of practice. This long learning process may help to explain the fact that different populations of the same species of bellbird may have very different repertoires. This is especially true of the Three-wattled Bellbird (*Procnias tricarunculatus*), which makes vertical migrations from lowland forest up to montane forest areas physically well separated from one another (see Movements).

The White Bellbird's double "ding ding" is unusual in another way. It may be uttered with the head and body held still, or, in its loudest form, with a swing from right to left. In the latter instance, one "ding" is given as the bird leans to the right and the

On account of their remarkable morphology and their habit of nesting on rocks rather than trees, the cocks-of-the-rock were previously granted their own family. Their vibrant orange plumage, strange fan-like crests and conspicuous leks call to mind some birds-of-paradise (Paradisaeidae) from the island of New Guinea. Although in colour, crest-shape and nesting behaviour they are unique amongst South American birds, they also possess various features typical of cotingas and as such they are now usually subsumed within the Cotingidae.
The Andean Cock-of-the-rock (Rupicola peruvianus) *is widespread in the Andean chain from Venezuela to Bolivia, while the* ***Guianan Cock-of-the-rock*** *occurs in the continent's north-eastern region, in forests of the Guianan Shield. Both of these species inhabit the lower and middle strata of forests, where they are often quite shy away from leks. As might be expected, their gaudy plumes have attracted attention for centuries, appearing in the ornaments and apparel of tribespeople and aristocracy alike. Along with the great macaws,* Ara *and* Anodorhynchus, *and the Toco Toucan (*Ramphastos toco*), they are the most famous of Neotropical birds, emblematic of the South American avifauna in all its richness and idiosyncrasy.*

[*Rupicola rupicola*, French Guiana. Photo: Cyril Ruoso/Bios]

On the basis of several features, the genus Phoenicircus *seems to form a link between two sister-families, Cotingidae and Pipridae. In their short wings and tail, intense carotenoid-rich plumage, and foot structure, red cotingas look like giant manakins. Similarly, their displays involve acrobatic flights and dual sound production, both mechanical and vocal. They resemble manakins in their ecology, eating berries and forming leks in the lower strata, but differ from them in being very thinly spread in apparently ideal habitat. Searching for the* ***Black-necked Red Cotinga*** *in Amazonia can be a time-consuming process, but the prize of a male in adult plumage is well worth the effort!*

[*Phoenicircus nigricollis*, River Amazon, Peru. Photo: Michael & Patricia Fogden]

second one is delivered with a rapid swing of the head and body to the left. The wattle, greatly elongated during calling and display, typically hangs on the right-hand side of the bill when the call is made with a swing, so that it flies out behind the widely opened bill as the head swings to the left. Occasionally, the wattle gets to the "wrong" side; when this happens, the bird manoeuvres it back to the right side before making the call. In southern Guyana, where B. K. Snow carried out the only careful study yet made of the White Bellbird, several individuals were watched, and all were "right-wattled". It is worth noting, however, a series of photographs that show that the recently discovered population of the Serra dos Carajás, in south-east Pará, may be "left-wattled", at any rate to some extent.

A final point relating to the bellbirds' explosively loud calls concerns the way in which they are produced. It has been known since the eighteenth century that the production of sound by a bird's vocal organ, the syrinx, depends on air pressure in the interclavicular air-sacs that surround that organ, and more recent research has demonstrated that loud calls, with energy distributed over a wide frequency range, as is the case with the bellbird's calls, must be associated with high pressure in the surrounding air-sacs. It is therefore of interest that a bellbird's loudest calls are preceded by sudden inhalations of air, as vividly described by J. J. Quelch in an early account of a captive White Bellbird.

> "When the appendage [the wattle] is fully elongated, the bird suddenly inflates its lungs, right and left, by inhaling – almost by a swallowing action – two great draughts of air; but the method by which this is done depends upon which of its two characteristic notes it intends to utter. When the notes 'Kong-Kay' [here transcribed as 'ding ding'] are uttered, the action of inflation has been performed by two distinct inhalations of air, one with the head turned to the right and the other immediately after to the left. At the moment of utterance of the notes, the head is turned to the right for the 'Kong', and then suddenly – so suddenly that it almost startles the observer – the head is swung round to the left for the 'Kay', which is issued with a strikingly loud, piercing and metallic ring or clang – so loud and shrill indeed that, if the observer is close by, the ears are actually deafened for the moment by the sharpness of the sound."

It should be noted that the captive individual described by Quelch, in the late nineteenth century, was "right-wattled", just as virtually all of those more recently observed.

Among other very striking cotinga calls are the booming notes of the umbrellabirds and the Red-ruffed Fruitcrow. All observations indicate that these vocalizations are preceded by inflation of the air-sacs in the anterior part of the body. This involves the conspicuous inflation of the bare red-skinned wattle of the Bare-necked Umbrellabird (*Cephalopterus glabricollis*) and the puffing-out of the Red-ruffed Fruitcrow's feathered throat into a red balloon, and it seems that the calls produced acquire their resonant booming quality from the air in these sacs and, probably, in the buccal cavity. In sharp distinction from the bellbirds, which give their loudest calls with the bill held open to its fullest extent, these fruitcrows keep the bill closed.

"Thus, also in the forest," wrote E. F. im Thurm in 1883, in *Among the Indians of Guiana*, "is heard an extraordinarily deep sound, like the lowing of an ox, and it is long before the traveller realizes the fact that it is made by the 'quow' or 'calf-bird'." This strange call, which male Capuchinbirds utter at their leks (see Breeding), is very different in quality from the umbrellabirds' boom. It begins gradually and is long drawn-out, and it is evidently more conventionally produced. There is no visible inflation of air-sacs, and the call is given with the bill open.

Probably the best-known cotinga call, heard by millions as it is frequently used as a background sound in television programmes and films dealing with South American natural history and travel, is the piercing "pi pi y-o" of the Screaming Piha.

*The **Scaled Fruiteater** is an odd bird with short wings, scalloped plumage and a raptor-like song. The female, pictured here, is more strikingly patterned below than the male, whose underparts are scalloped olive, not black. The male, however, has a much more striking head pattern, including a glossy black crown. This individual has been feasting on palm fruit, but the species often moves along horizontal boughs in the middle storey, snatching large insects and other food items, sometimes during short aerial sallies to adjacent branches and foliage. Perhaps rather oddly, it also eats arboreal snails, beating them against branches to remove part of the shell.*

[*Ampelioides tschudii*, Ecuador. Photo: Greg Dean]

This is uttered by the dull-plumaged males while they are perched inconspicuously in loose groups in the middle storey of the forest, so that the callers themselves can often be difficult to detect. The call is preceded by two much less loud notes, somewhat like those of a dove (Columbidae), "groo, groo", which are probably accompanied by inhalation of air; the bird then suddenly jerks its head back, so that it almost rests on its scapulars, and utters the first syllable with the bill widely open, displaying the orange mouth; it then makes a second backward jerk for the second syllable, before relaxing forward and half-closing the bill for the final "y-o". The quite violent and ritualized movements accompanying the vocalization give the impression of being physically essential to its production, but they are probably really a visual display, as the bird occasionally makes another equally loud call without any movement of the head or body.

Limitations of space prevent a comprehensive treatment, but no account of cotinga voices can omit the remarkable chorus of the Black-and-gold Cotinga. This species' call is an extremely pure whistle lasting about 3 seconds, and the interval between successive calls is approximately 2 seconds. Groups of males call in chorus, timing their calls in such a way that even just two males vocalizing together can produce continuous sound. The pure whistling, sometimes continuous for minutes on end, is an unforgettable sound of the steep wooded mountains in this cotinga's very limited range in south-east Brazil.

The song of the male Sharpbill is exceptionally distinctive. It is an extremely firm sharp whistle, lasting 1-3 seconds. The whistle starts at a frequency of about 3 kHz and descends over a wide interval, from a fourth to as much as a full octave; it has been likened to the sound made by a falling bomb, but without the terminal "boom". While singing, the male stretches his neck forwards and fluffs out the neck feathers, but does not expose his red crest. This contrasts with the mechanical-sounding rasp emitted by the plantcutters, which is similar to the sound produced by the winding of an old-fashioned alarm clock.

Some cotingids are so silent that it has been supposed that they are voiceless. This is so for nearly all of the blue cotingas and also for the Bare-necked Fruitcrow, and few or no vocalizations have been recorded for a number of others. In some genera in which the males are conspicuously vocal, the females seem to be voiceless; the best-authenticated case is that of the Bearded Bellbird. Caution is needed, however, for any species if its nesting behaviour has not been studied. For example, Skutch recorded that a female Lovely Cotinga, hitherto thought to be voiceless, uttered loud screaming calls when mobbing a toucanet (Ramphastidae) that perched near her nest, and later, when he was searching for a nestling which had fallen from the nest, she constantly uttered a low "ic, ic, ic". On the other hand, a female Bearded Bellbird remained quite silent, perched nearby, when a

*The **Crimson Fruitcrow** is a large canopy-dwelling cotinga for which a separate genus is required. It shares some features with the white-winged cotingas of the genus* Xipholena, *but its taxonomic relationships are unclear. The male is mostly glossy crimson, with a heavy reddish bill. In females, like this individual, the bill is blacker, the head and underparts rosy, and the plumage otherwise dusky brown. Flight is heavy and undulating, like an umbrellabird* (Cephalopterus), *but the male performs a unique display. He climbs 30 m above the canopy then parachutes down to a tree-top perch, sometimes spiralling, with feathers puffed out and wing and tail fanned.*

[*Haematoderus militaris*, San Diego Zoo, USA. Photo: Josep del Hoyo/ Lynx Edicions]

*Another bizarre species is the **Bare-necked Fruitcrow**. Within the context of the cotingas, the wrinkled facial skin is unique, and large powder-down patches on the flanks almost so. Although this species is numerous around Amazonian wetlands and rivers, little is known about its social organization except that it regularly forms flocks. Parties of individuals are most likely to be seen in sustained flight, high above the canopy, as they pass from one food source to another, at least one of which is liable to be a* Cecropia *tree full of ripe fruit. These "catkins" (pictured here) are a favourite food of a variety of cotingids, as well as of other frugivores.*

[*Gymnoderus foetidus*, Amazonas, Brazil. Photo: Luiz Claudio Marigo]

chick was periodically taken from the nest, examined and photographed. The single nestling, too, was silent throughout its time in the nest, and it seems likely that this is the case for at least some other cotingas, the entire nesting strategy of which is based on the need to be inconspicuous.

As mentioned above (see Morphological Aspects), the males of several cotingid species produce mechanical wing noises in flight, mainly in the course of courtship display. In the case of the Black-necked Red (*Phoenicircus nigricollis*) and the Guianan Red Cotingas (*Phoenicircus carnifex*), this noise is combined with a vocal call, a phenomenon apparently unique within the family; as the displaying birds fly between perches, they produce a two-part mechanical whistling sound, apparently with the highly modified 7th primary (see Morphological Aspects), followed immediately by a vocal whistle. The two red cotingas are very little known, and only the Guianan species has been occasionally heard also to make a loud, two-part buzzing sound during a short upward flight. The wing noises made in flight by male blue cotingas in the genus *Cotinga* are better known, but their significance is still uncertain. They are usually described as rattling, whirring or whistling sounds, and they apparently differ among the various species in the genus, as do the modifications of the outer primaries. The sound is made in normal flight, but more loudly in display, as is typified by the Plum-throated Cotinga.

The most remarkable of the mechanical wing noises made by a cotinga is that recently described for the hitherto poorly known Dusky Piha of the Andes. The male takes off from a high tree perch and descends steeply towards the ground, making a series of loud, low-frequency sounds as it momentarily opens the wings, umbrella-like, as if trying to slow its fall, and then closes them again, performing this wing action up to twelve times. It then flies up to another perch in an adjacent tree. The sound, described as "almost deafening" at a distance of 10 m, is produced during the sudden opening of the wings. The sequence of sounds resembles that made by the flight-feathers of the much larger and better-known Sickle-winged Guan (*Chamaepetes goudotii*), and was identified as such by local people. It is remarkable that the structural modification responsible for the sound is restricted to the middle part of the outer webs of three primaries, the barbs of which are elongated, stiffened and non-interlocking.

*The cotinga family contains more than its fair share of large and spectacular species. The **Red-ruffed Fruitcrow**, which certainly fits this category, seems most closely related to the umbrellabirds, but unlike them it rarely flies across wide clearings. Males gather in typical leks (rarely found), where they produce deep booming calls and puff out their throats into bright red balloons. This species is quite rare throughout much of its range, except in the Atlantic Forest of south-east Brazil, where the nominate race is relatively common. It seems likely that its population is denser in this particular forest block because of a lack of direct competitors.*

[*Pyroderus scutatus occidentalis*, near Otún-Quimbaya Fauna and Flora Sanctuary, Risaralda, Colombia. Photo: Otto Pfister]

Food and Feeding

Except for the atypical plantcutters, which are adapted for leaf-eating and bud-eating, the cotingas feed mainly on fruit, some apparently exclusively so. In the Neotropical forests, the large cotingids, together with the toucans (Ramphastidae), are the main

*The **Handsome Fruiteater** is virtually restricted to humid forest, and in this respect is typical of almost all members of the family. It ranges from the middle storey to the subcanopy, looking for the fruits on which it mainly subsists, sometimes joining mixed-species flocks. This cotinga is common in the coastal ranges of Venezuela where it occurs between 800 m and 2200 m.*

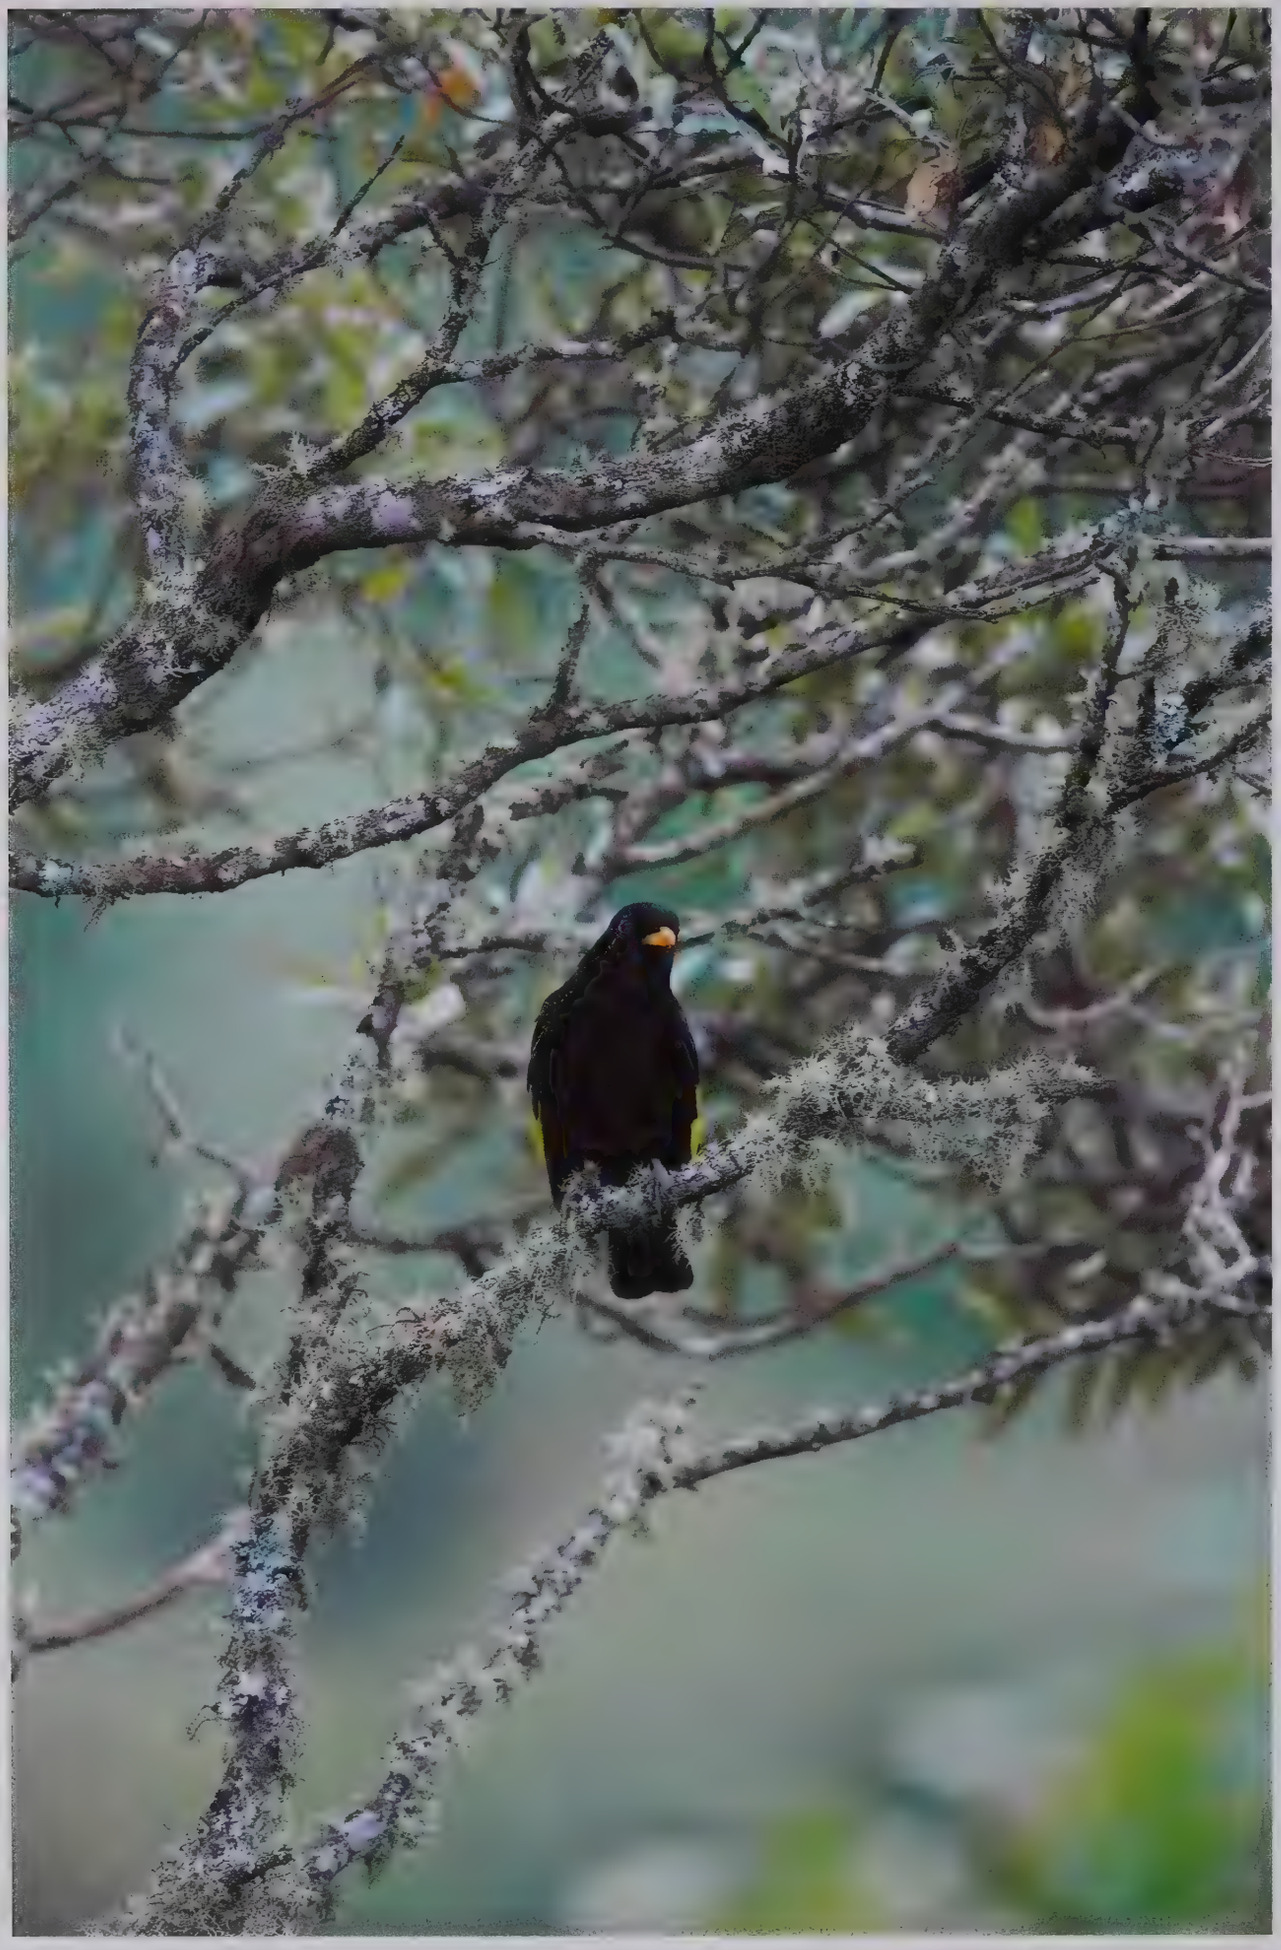
[*Pipreola formosa*, Venezuela.
Photo: Neil Bowman/FLPA]

avian dispersers of the seeds of large trees bearing fleshy fruits; they digest the fruit pulp, thereafter regurgitating large seeds and defecating small ones. This distinguishes them from the other important family of large frugivores, the parrots (Psittacidae), which digest the seeds, usually rejecting the pulp, and thus play a very different ecological role, that of seed-predators rather than seed-dispersers.

The exception to this general rule is the three plantcutters. Although they do consume fruits, they feed primarily on buds, shoots and leaves, as well as on grasses and flowers. The Rufous-tailed Plantcutter (*Phytotoma rara*) is known also to take insects to a minor degree, and the same probably applies to the other two species.

Two plant families are very important in that their abundant and easily accessible fruits are eaten by almost all frugivores, both large and small. These are the Cecropiaceae, containing the genus *Cecropia* (formerly placed in Moraceae), and the Araliaceae, especially the species *Didymopanax morototoni*. Apart from these, the recorded spectrum of fruits eaten by cotingas varies according to the size of the bird, and reveals that some cotingids have marked preferences for particular kinds of fruit.

The more thorough studies that have been carried out show that each species, even within limited areas, exploits a wide range of fruits, a small number of which are of greatest importance. For example, a detailed study of the Guianan Cock-of-the-rock at one locality during a period of just one month revealed that the birds took at least 65 species of fruit belonging to 31 plant families; of these, however, the Annonaceae, palms (Arecaceae), the incense family (Burseraceae) and the laurel family (Lauraceae) were clearly the most important. A study of the Bearded Bellbird in a small area in Trinidad showed that the species ate at least 41 different kinds of fruit from 20 different plant families, of which the Lauraceae was by far the most significant, followed by the Burseraceae and the Melastomataceae. Other studies, focused on the two cock-of-the-rock species and on the large fruitcrows, confirm the importance of the palm, incense and laurel families, and in addition the nutmeg family (Myristicaceae), all of which have very nutritious pulp or arils, rich in proteins and fats.



Knowledge of the diets of the medium-sized blue, white-winged and white cotingas is much more fragmentary. This is because these are highly mobile birds, and they have no traditional display perches below which regurgitated or defecated seeds can be collected. For the blue cotingas, it seems that, in some areas, figs (*Ficus*) are an important component in the diet, as also are the fruits of small palms (especially *Euterpe*), laurels and mistletoes (Loranthaceae). On the upper Amazon, Plum-throated and Spangled Cotingas have been recorded as flying daily for considerable distances in order to feed on the large fruits of a *Psittacanthus* mistletoe growing on an isolated tree. Just able to swallow these fruits, which were 25 mm long and 16 mm in diameter, they regurgitated the single sticky seeds, wiping them off on the branches on which they perched and leaving them hanging there. The birds' behaviour was no doubt responsible for this particular tree being loaded with mistletoe plants, while other trees in the neighbourhood had none.

Smaller mistletoe berries are an important component of the diets of the purpletufts and the high-Andean cotingas. Indeed, one of the most striking cases of mutual dependence between bird and plant is that of the White-cheeked Cotinga and two mistletoe species in the Peruvian Andes. In the few areas where they have been carefully studied, in scattered *Polylepis* woodland above 3000 m, these cotingas of very restricted range fed only on fruits of the two mistletoes, of the genera *Tristerix* and *Ligaria*, which were the only fruit-producing plants present at this altitude. After feeding, they would fly to another perch in a *Polylepis* tree and regurgitate the seeds, wiping them off on to the surface of a limb. Examination of the trees revealed many seeds, a few in various stages of germination. Even more re-

Like most other cotingids, cocks-of-the-rock occur in humid forests, but their distribution is constrained by specialized nesting habits. They are reliant on cliff faces and other sheer walls of rock for their nest-sites, and thus the ***Andean Cock-of-the-rock*** *tends to occur in gulleys and ravines in mountainous regions, wherever bare outcrops of rock can be found. Despite their striking plumage, they tend to be quite retiring. In normal circumstances they are most commonly noticed when a ball of glowing orange or red slips through the forest out of sight, or swoops across a gap such as a road, or a river. At some localities they are common birds, even where forest is fragmented. In such places, they can be seen at forest borders, even perching on fence posts and in isolated trees.*

[*Rupicola peruvianus saturatus*, Peru. Photo: Patricio Robles Gil/ Sierra Madre]

A beautiful black and yellow bird lives high in the Serras of south-east Brazil, where it is easy to hear, but difficult to see. In colour and pattern it is reminiscent of a cacique (Cacicus)*, but its bill and behaviour are distinctly cotingid. The* ***Black-and-gold Cotinga*** *lives in the canopy of cloudforest, often concealed in the dense crowns of stunted trees, but at other times emerging to perch prominently on bare boughs. Its true abundance is only revealed by the distinctive song of males, one of the characteristic sounds of montane forest in the states of São Paulo and Rio de Janeiro. Two or more males regularly perch and emit their pure-tone whistles concurrently. Each bird pauses for a couple of seconds between songs, but when two or more males sing at once the pauses of one bird are typically overlain by the songs of another. The effect is a strange meandering ventriloquial note, a bit like the singing of old-fashioned kettles. The affinities of* Tijuca *are unclear. Analysis of feather proteins suggests a link with* Lipaugus*, but the two genera should probably be kept separate on account of their quite different plumage and voice.*

[*Tijuca atra*,
Pico dos Marins,
São Paulo, Brazil.
Photo: Edson Endrigo]

The only non-forest members of the family are the plantcutters (Phytotoma). *All three members of this genus are birds of relatively open habitats, such as low-stature dry forests and bushy country. The* ***Rufous-tailed Plantcutter****, for example, lives in farmland, hedgerows, gardens, and patches of thorny scrub. It is seen here in Los Glaciares National Park, with the famed parapet of Cerro Torre in the background. It ranges far further south than any other cotingid, even occurring on Tierra del Fuego.*

[*Phytotoma rara*, Los Glaciares National Park, Santa Cruz, Argentina. Photo: José & Adriana Calo]

markably, members of a mated pair were seen to engage in mutual display, facing and close to one another, in the course of which both partners regurgitated mistletoe seeds on to the surface of the *Polylepis* branch. It is of interest that a White-cheeked Cotinga, watched recently in the Cordillera Blanca, in the north of the species' range, was seen to eat the buds of a shrub identified as *Berberis lutea*; further study is required in order to establish whether this is a regular habit.

An important point, but one that is difficult to settle, is the question of whether any of the Cotingidae are exclusively frugivorous. Perhaps the best candidates are the bellbirds. Systematic observations of adult bellbirds indicate that they feed entirely on fruit, and at the only successful nest that has been recorded the nestling was also fed solely on fruit. There is, however, an old record of snails being found in the stomach of a Bare-throated Bellbird, and it may be that egg-laying females supplement in this way what might otherwise be a calcium-poor diet; unfortunately, the sex of the individual concerned was not recorded. In this context, the Scaled Fruiteater has recently been observed to eat arboreal snails of the genus *Plekokeilas*, apparently regularly, in north-west Ecuador, but in this case, most interestingly, both sexes consumed the molluscs, which they beat against a branch in order to remove the outer lip of the aperture, and then swallowed whole. A male was seen to capture a snail by plucking it from the underside of a tree branch in an upward sally from a lower perch. The *Phoenicircus* red cotingas and the Andean fruiteaters of the genus *Pipreola* appear, so far as records go, to be entirely frugivorous, but the possibility remains that, as with so many cotingas and other birds, they occasionally exploit the aerial swarms of winged termites (Isoptera) or ants (Hymenoptera). This has recently been documented for Spangled Cotingas and Pompadour Cotingas (*Xipholena punicea*), both of which were previously thought to be exclusively frugivorous.

Apart from the above-mentioned examples of snail-eating, it seems that insects and, in the case of some of the large cotingid species, small vertebrates form the non-fruit part of the diets of the family. Insects are usually taken in short aerial sallies or plucked in flight from foliage or branches. An exception is the Scaled Fruiteater, a short-winged species, which has been described as hopping along horizontal branches in search of insects. Likewise, the Sharpbill, when catching arthropods, may hop along high branches, probing into tufts of moss or epiphytes; it can also move with great agility among the leaves of the outermost twigs of the canopy, often hanging upside-down and making rapid pecks into the bases of leaf clusters.

The fruitcrows, to judge from the small number of nests observed, feed their young mainly with insects, supplemented by an increasing amount of fruit in the later stages and, in the case of the Capuchinbird, an occasional small lizard. The two cocks-of-the-rock, although of fruitcrow size, differ from them in that they feed their nestlings not only with fruit, but also with significant quantities of small vertebrates, mainly lizards and frogs; at some nests, the young may be fed almost entirely with vertebrates. In addition, there is a single record of a Screaming Piha eating an *Anolis* lizard, and one of a Capuchinbird taking a small bat (Chiroptera) from thick foliage and, after battering it against a liana, flying off with it, presumably to feed it to its young.

A final point, of theoretical interest, concerns the question whether, or to what extent, the cotingids and their fruit plants have co-evolved. Some of those cotingas with a short bill and a very wide gape, of which the bellbirds are the most extreme, are clearly adapted to feeding on fruits that are very large in relation to their own body size. They are also able to get rid of large seeds, which are, from the birds' point of view, useless "ballast", by regurgitation after only a few minutes. The most important plant families which they exploit, especially the laurel, palm and incense families, have fruits with pulp rich in fats and proteins, as well as carbohydrates, and seeds which do not adhere to the surrounding pulp, thus facilitating rapid regurgitation; in most cases, they also present their fruits in a manner that makes them accessible to a sallying bird. These and other facts all suggest a long process of co-evolution between plants and avian frugivores. Nevertheless, apart from the above-mentioned example of White-cheeked Cotingas and two mistletoe species in an extreme, marginal environment, there is no known case of a cotingid being dependent on one, or even a few, plant species, or of a plant being dependent for its dispersal on a single cotinga species. Furthermore, the evidence from paleobotany indicates that plant evolution has been much slower than avian evolution, and that fruits very similar to those observed today were in existence long before the evolution of recent bird species. It seems probable, therefore, that the cotingas have become adapted to fruits the characters of which are the result of a very long process of selection by successive avifaunas.

Although the great majority of cotingids appear to forage solitarily or in pairs, the plantcutters often feed in small groups or, occasionally, in large flocks. Indeed, flocks of White-tipped Plantcutters (*Phytotoma rutila*) containing up to 100 individuals have been recorded. The plantcutters differ further from the majority of the other members of the family in that they do not make

Due to their frugivory, cotingids spend a relatively small proportion of their time foraging: it is much easier to fill up on static fruit than to hunt mobile insects. Given an abundance of spare time, they spend hours on end singing during the reproductive period, or loafing and preening at other seasons. This ***Bare-throated Bellbird*** *is taking advantage of an easy schedule by arranging the feathers on its chest. Allopreening has not been reported in the family, and the same goes for "sun-bathing". Nonetheless, this latter behavioural trait might well take place on top of the canopy, where cotingas are especially difficult to observe.*

[*Procnias nudicollis*, Misiones, Argentina. Photo: José & Adriana Calo]

aerial sallies to obtain their food; instead, they feed while perched in shrubs and trees, and they also forage at times on the ground. Bearing in mind the largely herbivorous diet of the plantcutters, these differences are hardly surprising.

Breeding

Knowledge of the breeding of the Cotingidae is still fragmentary. The nests of eight of the genera, and of 33 of the 71 species, are unknown. No quantitative data are available for any species except, to a limited extent, the Guianan Cock-of-the-rock, the unusual nest-site of which makes its nests comparatively easy to find and reach.

Indirect evidence of breeding seasons is more easily obtained by examining the dates of museum specimens which are undergoing a full moult, including that of the flight-feathers and tail feathers. Even so, although the full moult of adult birds generally takes place immediately after the end of a breeding season, the males of some of the highly dimorphic cotingas begin the moult well in advance of the females, so that only the latter sex can be used to indicate the breeding season. Moreover, the information so gained does not reveal when breeding began. With these caveats borne in mind, the moult data combined with available nesting data indicate that, north of about 8° N, the main breeding season of cotingids, as that of most other Neotropical landbirds, is from about March to June, with a peak in April or May, while that in lowland areas south of about 15° S is generally from about September to December; in intermediate lowland areas, and over a wider latitudinal extent in the Andes, breeding shows no clear seasonal pattern. From the little evidence available, the Buff-throated Purpletuft (*Iodopleura pipra*) in south-east Brazil is a notable exception. This globally threatened species breeds in the middle of the austral winter, with egg-laying recorded in July, although a singing male has also been observed in December.

Adults of a few cotingid species, in particular the *Pipreola* fruiteaters, the purpletufts, the Black-faced Cotinga and the plantcutters, apparently live in pairs, and both sexes attend the nest. Those of some others do not form pairs, and the males are polygamous, either actually or potentially, depending on their social status; they display in groups and, for the few species studied, one or a small number of dominant males perform all matings. In these cases, females alone attend the nest. For many other cotingids, although there is often at least some evidence that only the female attends the nest, the mating system remains unknown. This is the case for the treetop-inhabiting blue cotingas in the genus *Cotinga*, the white-winged cotingas in *Xipholena* and the white cotingas in *Carpodectes*. One major exception is provided by the Purple-throated Fruitcrow, the males and females of which live together in small, tightly knit social groups containing up to eight individuals. Thus, the diversity of social organization within the Cotingidae is great, and the following paragraphs are necessarily selective, rather than being a comprehensive account of what is known.

The Guianan Cock-of-the-rock is unique among the family in that groups of males display on the ground and are often highly conspicuous. For this reason, in addition to the fact that its nests are comparatively easy to find, far more is known about this species than about any other member of the family, thanks mainly to a lengthy study by P. W. Trail in Surinam. Up to 50 or more adult males, aged three years or older, may be established at a lek, the site of which may remain unchanged for years. Each male has its own "court" on the forest floor, but spends much of its time in the low branches of trees just above, defending the surrounding perches up to a height of 1-2 m, and engaging in regular bouts of aggressive display with its neighbours, accompanied by much raucous crowing. On the arrival of a female, or females, in the trees above, all males present at once fly down to their courts, where they land with a bounce and flutter, which effectively blows away all debris and keeps the courts clear and smooth; they then crouch motionless and silent, with the upper plumage spread to form a patch of brilliant orange fringed with the silky filaments of the rump feathers and secondaries. The drab-coloured females move down to low perches in the trees above, inspecting the displaying males. A female that is ready to mate eventually descends to a court, landing behind the male. She may rest her head on the "pillow" of his rump feathers, or nibble at the fringes of his rump and wing feathers, until eventually the male hops around and mounts her. At the large lek most intensively studied for several years, in Surinam, 51-61

During the breeding season, males of many species vocalize from prominent perches. This ***Black-and-gold Cotinga*** *is taking a break from long bouts of singing, and indulging in some preening and wing-stretching. Like* Tijuca, *the four bellbirds often sing from high bare branches, though with very different songs. A male Bearded Bellbird* (Procnias averano) *watched from dawn to dusk spent 87% of his time on one favoured perch, 74% of it singing! Of course, the best males will be able to afford more time singing, thus providing a measure by which female cotingas may be able to choose high-quality mates.*

[*Tijuca atra*, Pico dos Marins, São Paulo, Brazil. Photo: Edson Endrigo]

Of the many and varied calls produced by cotingids the best known is that of the ***Screaming Piha****. So loud and diagnostic, and so often used as a backing track to documentaries on natural history, it has virtually assumed the status of a "signature tune" for Amazonia. Living in the dim middle storey, male pihas have forgone bright coloration, and invested everything into their vocal signal. They perch in loose gatherings, or "exploded leks", and sing for much of the day. First, they give a series of cooing notes, rising in pitch. Then they unleash the piercing "pi pi y-o". This finale is produced with what looks like a good deal of effort, and it is astonishingly loud. Standing in the midst of a busy lek is an unforgettable experience, although the birds themselves can be frustratingly difficult to see.*

[*Lipaugus vociferans*, Descobrimento National Park, Bahia, Brazil. Photo: Johannes Ferdinand]

males were present each year, and the courts were densely crowded, some as little as 1-2 m apart. Nearly all matings were performed by a small number of males that occupied central courts. Females clearly made some choice; before mating, they visited the courts of a number of males over a period of several days, usually mating with only one of them. Occasionally, violent and prolonged conflicts took place between males disputing ownership of a court. Other leks of this species at which observations have been made were smaller, with fewer males.

Less is known of the behaviour of the Andean Cock-of-the-rock. The most striking difference between the two congeners is that males of the Andean species display not on the ground, but 4-6 m above it on low perches, which the birds keep almost devoid of leaves by plucking them, using both the bill and the claws. A further difference, at least at the only two leks studied in detail, one in Colombia and a larger one in Venezuela, is that the males are in pairs, the members of each of which regularly perform ritualized bowing displays towards one another. At the smaller of the leks studied, consisting only of three pairs occupying a display area 20-25 m across, one male was dominant and performed all the observed matings. Much larger leks, containing some dozens of males, have been reported elsewhere, however, and it seems unlikely that such a simple dominance hierarchy could be maintained at leks of this size.

The lek organization and displays of the bellbirds are very different. Only the Bearded Bellbird has received detailed, sustained study, by B. K. Snow in Trinidad, but less complete observations of the three other species suggest that they follow the same pattern. Groups of males are much smaller, those studied consisting each of three or four individuals, and the birds are spaced 100 m or more apart. They advertise themselves by uttering amazingly loud hammer-like or bell-like calls (see Voice) from exposed treetop perches, but the females are not courted on these high perches. When a female has been attracted, the male flies steeply down to a special small understorey tree in the forest below. If the female follows him down and is receptive, mating eventually takes place on one particular horizontal side branch of the tree, following an elaborately ritualized series of calls and jumps by the male, culminating in a final explosive "bock" as it leaps on to the female's back. One of the movements involved in the male's preliminary display consists of ritualized preening under the wing, accompanied by prominent display of a patch of bare pinkish skin on the side of the thigh.

At the Bearded Bellbird lek most intensively studied, there were three calling territories, one of which was most favoured. Competition for this territory was intense. When the owner was trapped for ringing, no doubt a traumatic experience for him, he disappeared and his place was at once disputed by the other two males, one fully adult and the other still with a few juvenile

A group of cotingids that owe their common name to the sound of their voice are the bellbirds. Male bellbirds make what are probably the loudest and most far-carrying of all passerine calls. The White Bellbird (Procnias albus) *sounds like the chiming of a bell, but the* ***Bare-throated Bellbird*** *makes more of a tuneless clang, like a hammer hitting an anvil. Information from captive birds suggests that it takes a year for a young bellbird to perfect his call, even when housed with an adult male. In terms of voice, Cotingidae is a family of extremes. Some species rarely fall silent, while others have rarely, if ever, been heard to call.*

[*Procnias nudicollis*, Brazil. Photo: Nick Gordon/ Nature Picture Library]

Most cotingas rely on fruiting trees for much of the year. In general, they favour the fruit of the palm (Arecaceae), laurel (Lauraceae), incense (Burseraceae) and nutmeg (Myristicaceae) families. These trees often bear fruit with nutritious pulp and arils, rich in proteins and fats.
This ***Purple-throated Fruitcrow*** *has been picking individual fruit while perched, but when food items are less accessible they are plucked during short fluttering sallies.*
An aberrant member of the family, this fruitcrow's closest relatives are uncertain. Within Cotingidae, it is remarkable as being a social species, usually found in noisy groups of 3-8 birds, even when nesting. Indeed, it is the only member of the family known to indulge in co-operative breeding.

[*Querula purpurata*, Panama.
Photo: Marie Read]

feathers; the fully adult bird succeeded in taking it. Similarly, during the annual moult, when the territory-owners were absent, their calling perches were temporarily taken by other males, mostly subadults. The general picture was of continual competition by a group of males, of varying ages, for a small number of traditional display territories, one of which was strongly favoured over the others.

Lek displays by males are a feature of several other cotingid species, including the umbrellabirds, the Red-ruffed Fruitcrow, the Capuchinbird and the Screaming Piha. As indicated earlier (see Voice), the umbrellabirds and the Red-ruffed Fruitcrow advertise with booming calls, the Capuchinbird with the extraordinary mooing call from which it gets its alternative name of Calfbird, and the Screaming Piha with a piercingly loud "pi pi yo", which has become almost the "signature tune" of the Amazonian forest, being used as a prominent background sound in many films and television programmes. Of these species, only the Capuchinbird has been studied in detail, by B. K. Snow in Guyana and, for a longer period, by Trail in Surinam. Apart from its bizarre appearance, displays and voice, it is of particular interest as an example of the significant minority of lekking bird species, nearly 25%, which are essentially monomorphic, the sexes being the same in plumage and not very different in size.

The Capuchinbird's lek behaviour exhibits some unusual features. Each season, a single dominant male performs all matings, but the site of the lek, unlike those of other species, changes from year to year; as a result, the dominant male has to establish his dominance afresh each season, without reliance on his previous possession of an established perch. The other males call and display on the surrounding perches, but do not constantly occupy and defend any particular one; in addition, they continually attempt to occupy the dominant male's perch. They also engage in paired displays with other subordinate males, perching side by side and calling alternately, avoiding any overlap in their calls. Such display partnerships, between the same two individuals, last for at least one complete breeding season. Females regularly visit the lek in groups, and while there they are highly aggressive towards one another. Furthermore, subordinate males regularly adopt female-like behaviour, which may allow them to approach, and even land on, the dominant male's perch, and females, conversely, sometimes adopt male display postures, apparently allowing them to supplant other females from the dominant male's perch. In these ways, the lek behaviour of Capuchinbirds differs strikingly from that of the highly dimorphic Guianan Cock-of-the-rock. Most interestingly, in the wake of these studies, Trail has suggested that plumage monomorphism among lekking species has evolved as a result of social competition affecting both sexes, rather than competition between males alone; this bare summary, however, does no justice to the complexity of the case and of the theoretical considerations that are involved.

*In its pointed tip, the beak of the **Sharpbill** differs from those of all other cotingids. This feature seems to owe its form to a suite of unusual foraging techniques. It is used as a tool to unroll curled leaves, and to probe inside leaf clusters, allowing the Sharpbill to reach insect larvae and spiders' nests. It can be poked into tufts of moss and epiphytes, from which other morsels can be extracted. And it comes in handy at dehiscing fruit, when it can be used to pluck ripe seeds from tough husks, as shown here. The Sharpbill is also unusual in that it joins mixed-species flocks, readily foraging in the outermost twigs of branches, and habitually hanging upside-down.*

[*Oxyruncus cristatus cristatus*, Itatiaia National Park, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

Although the breeding habits of the Sharpbill are very poorly understood, it is possible that this species uses an "exploded" lek system. This is suggested by the fact that the males are present for the greater part of the breeding season on their song territories, which tend to be arranged in clusters, with individuals in hearing distance of one another. It is not known, however, whether a female may visit several different males. Within his territory, each male appears to have some three to five singing perches, all within a radius of 100 m, that are used regularly. He gives about four songs from a perch, at the rate of two per minute, before moving to the next perch. Altogether, a male can spend as much as 80% of his time on song perches.

Among a number of cotingas with brilliantly or conspicuously coloured males, at least a part of the repertoire of courtship displays is aerial, taking place above the forest treetops. Not surprisingly, these have been little studied, and nothing is known

*In contrst to parrots (Psittacidae), which are seed-predators that digest the seed itself and defecate only pulp, cotingids are amongst the most important seed-dispersal agents in Neotropical forests. Like the toucans (Ramphastidae) they habitually eat fleshy fruit, as this **Bare-throated Bellbird** illustrates. They digest the pulp, defecate small seeds, and regurgitate large seeds, often far from the source tree. Many cotingas eat the berries of mistletoes (Loranthaceae) and other epiphytes. These have large sticky seeds, so that they attach to branches wherever they are wiped by cotingas. For a parasitic arboreal plant, this proves to be a perfect dispersal mechanism.*

[*Procnias nudicollis*, São Paulo, Brazil. Photo: Edson Endrigo]

One of the strangest displays in the family is performed by one of its most peculiar members, the ***Capuchinbird****. Placed in the monotypic genus* Perissocephalus, *the Capuchinbird seems most closely related to* Pyroderus *and* Cephalopterus. *Males in all these genera produce low mooing or booming noises, but the Capuchinbird sounds especially cow-like, whence the alternative name of Calfbird. Its leks are found by listening for the unlikely sound of lowing cattle high in the trees. At these leks, the dominant male defends a key perch, and subordinate males display nearby. They stand upright with bald heads gleaming, the curved orange undertail-coverts standing out like "tail-lights", and they moo. In trying to ascend the hierarchy, subordinate males will form alliances that last the entire breeding season. Allied males stand shoulder-to-shoulder, calling alternately, as can be seen in the upper photograph. The lek is visited by groups of females, often leading to chaos. Females resort to aggression, or mimicry of males, in an attempt to supplant their rivals. Meanwhile, subordinate males copy the behaviour of females and sneak towards the key perch in search of opportunistic matings. Thus, females compete with females, and males compete with males, a factor which goes some way to explaining their monomorphism, a rare characteristic in lekking species. Capuchinbird leks are situated in the upper canopy of tall rainforest, where only a lucky few have been able to watch them; but in hill forest in the Guianas, leks may be much lower down, only 9-11 m above the ground. The codes of conduct at these leks have only been partially deciphered, and the stratagems employed by both sexes are poorly understood.*

[*Perissocephalus tricolor*, Brazil.
Photos: Nick Gordon/ Nature Picture Library]

During display, the single wattle of the ***White Bellbird*** *is slowly extended, apparently by engorgement of blood vessels. It usually hangs on the right-hand side of the bill, and the double chime of the male ("ding-ding") is accompanied by a swing of the head to the left, which causes the wattle to stream out to the right, clear of the widely opened bill. If it happens to be hanging on the left-hand side, the bird flips it back to the right before making the double chime. All males studied thus far have been "right-wattled", but this bird, of a newly discovered race from the Serra dos Carajás, is "left-wattled"; the photographs are not inverted. Further research is merited.*

[*Procnias albus wallacei*, Serra dos Carajás, Pará, Brazil. Photos: Luiz Claudio Marigo]

about the social organization of the species concerned. The male Plum-throated Cotinga, when displaying, has been described by one ornithologist as leaving a high perch, flying slightly downwards, and then straight out over open space, often water, for about 40 m, there braking suddenly, with a loud whistling "whirr", and returning to its perch. Males of the *Xipholena* species make upward flights of several metres from a treetop perch, perform a half-turn at the top point, and descend steeply to the same perch while holding the wings and tail conspicuously spread; in the case of the White-winged Cotinga (*Xipholena atropurpurea*), the most closely studied of the three species, the descent is accompanied by a loud wing noise. The all-white male Yellow-billed Cotinga undertakes conspicuous display-flights between bare topmost branches of a tall forest tree, or longer flights from one treetop to another. The most spectacular of such flights, however, must surely be that of the Crimson Fruitcrow (*Haematoderus militaris*), which has been seen to fly steeply upwards from a treetop to a height of about 30 m, and then descend slowly with the wings held open, the tail fanned, and the crown, back and breast feathers all puffed out, making the bird appear "rather like a great crimson rugby ball".

Finally, the Purple-throated Fruitcrow has a social organization which is very different from that of any other member of the family, and not unlike that of some of the New World jays. It lives in small groups containing 3-8 individuals, all of which jointly attend a single nest, as well as foraging and roosting together as a unit. All group-members take part in defence of the nest, constantly mobbing intruders and effectively deterring almost all other bird species, including potential nest-predators such as large toucans, from approaching close to it. The fruitcrows are aided in this by the fact that they are not only fairly large, but also relatively long-winged and highly agile in flight. The nest itself, unlike those of most other cotingas, is not particularly inconspicuous, and the obvious presence of the black adults around it further draws attention to it. The whole nesting strategy is thus very different from that of the rest of the family. Nothing is known of the relationships between members of a group.

With the exception of the cocks-of-the-rock, which build large bracket-shaped nests of mud and vegetable material on rock walls, probably using saliva as cement, all cotingids for which relevant information is available build open nests on or among branches of trees or shrubs. These are of very diverse kinds. A few species, breeding at high altitudes in the Andes, construct substantial, well-insulated cup-nests, whereas the known nests of lowland-forest cotingas are nearly all small or very small, but not all of the same type. A nest of the Sharpbill, located at an elevation of 900 m in the south-east Brazilian state of Rio de Janeiro, consisted of petioles covered with mosses, liverworts and spider web, the whole cemented with saliva, and was placed just 1 m beneath the top of the 30-m canopy of the forest. The plantcutters, which live in more open habitats, build a shallow cup-shaped nest from thin dry twigs, lining it with root fibres and other softer material. This rather loose structure, 6-9 cm in height and with a diameter of 10-18 cm, is often placed up to 3 m above the ground inside a thick thorny shrub, but sometimes higher up in the fork of a tree.

Among the most striking, at least to the few ornithologists who have found them, are the relatively tiny nests of some of the fruitcrows, pihas and other medium-sized cotingids. Such nests, placed on a fork of a slender horizontal branch, or between adjacent twigs, consist of a number of interlacing twigs, vegetable fibres or tendrils, forming a small shallow saucer or tiny cup. In several cases, the observer has thought at first that the bird was simply crouching on its perch, no nest being visible. Thus, Skutch, in his account of the first Rufous Piha (*Lipaugus unirufus*) nest that he found, some 6 m up in a small tree in Costa Rica, wrote:

> "Support was provided by two, slender, parallel, horizontal twigs, each about a quarter of an inch [0·6 cm] in diameter. Between these twigs the piha had built a nearly flat pad about three inches [7·5 cm] in diameter and somewhat less than an inch [2·5 cm] in thickness. It was composed almost wholly of wiry tendrils, many of which were coiled.... The whole fabric was light brown in color and so loose and open that I could read a printed page through the middle of it. Green foliage had formed a canopy close above it."

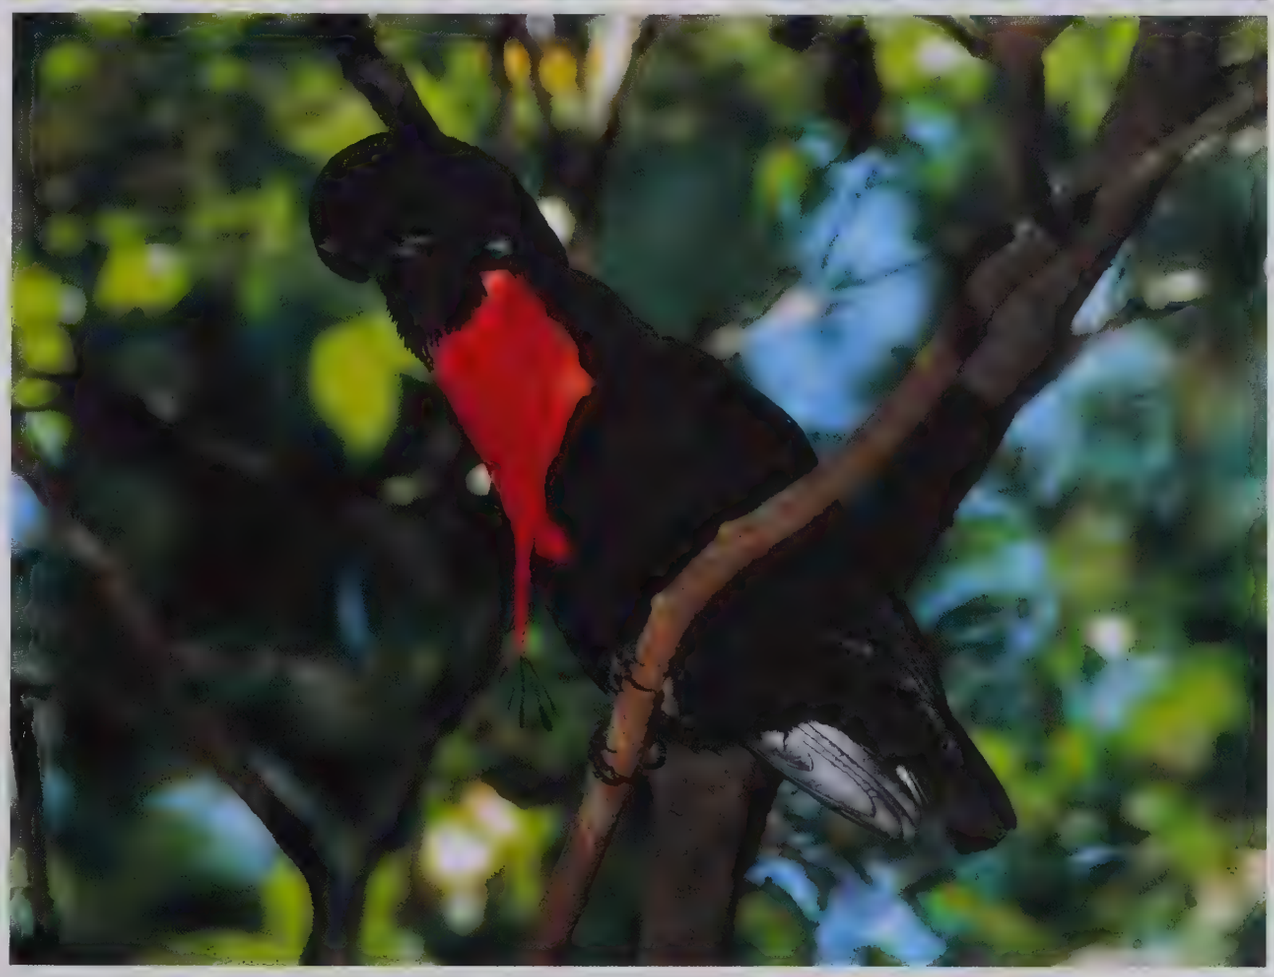
The nests of this kind that have been examined have consisted of materials which, although scanty, are well suited to forming a coherent structure, and are obviously very carefully selected. Nests of the Bearded Bellbird in Trinidad, for example, had a base consisting mostly of a small number of bifurcating twigs with club-shaped ends, very suitable for interlocking, of a tall forest tree, *Terminalia obovata*, with a shallow cup, remarkably tough and durable, consisting entirely of the very fine bifurcating, slightly curved and springy twigs of a smaller tree, *Maprounea guianensis*.

The only bellbird studied in detail is the Bearded Bellbird (Procnias averano)*, but behaviour is probably similar throughout the genus. Males call from high bare branches, either alone or at scattered leks. Females visit a series of males before selecting a mate. Then, at least in the* ***Three-wattled Bellbird,*** *she visits him repeatedly, often perching alongside for prolonged periods, as in the case seen here. Once a male has attracted a female with his songs and triple-pronged facial appendages, he drops to an understorey perch. If she follows, he performs a ritualized display on a horizontal branch, upon which mating eventually takes place.*

[*Procnias tricarunculatus*, Monteverde Forest Reserve, Costa Rica. Photo: Michael & Patricia Fogden]

The only recorded nest of the Pompadour Cotinga was a minute but deep open-work cup, composed of a few woody tendrils, into which the single egg fitted neatly. Similarly, only one Bare-necked Fruitcrow nest has been documented in detail, a very small saucer-shaped structure, not more than 10 cm in diameter, consisting entirely of lichens and fine tendrils of a climbing plant, and placed on a thick horizontal branch, the nest bottom being formed by the branch itself; it could not possibly have held more than a single chick of this rather large cotinga. Finally, to complete the range of very small cotingid nests that have been described in detail, the purpletufts build a tiny cup-shaped nest, very like that of a hummingbird (Trochilidae), fixed by spider web to a thin horizontal branch in a treetop, and again too small to hold more than a single egg. It is very probable that other members of the family construct nests that are equally tiny in relation to the size of the bird, but these have as yet not been adequately described.

These very small nests seem to be adapted primarily to be as inconspicuous as possible, a most important requirement in tropical forest, where rates of nest predation are very high. A light, open-work structure may also be important in preventing the nests from becoming sodden in heavy rainfall. The extreme reduction of clutch size, to a single egg, is therefore, it seems, a consequence of nest size, and not of the inability of the parent bird to feed more than one young. In the absence of evidence, this theory must remain speculative, but it should be noted that the only medium-sized or large cotingas that lay two-egg clutches are the two cocks-of-the-rock, their massive nests being comparatively safely located and often conspicuous. A puzzling possible exception, however, is the Purple-throated Fruitcrow, which lives in small social groups all members of which join together in defending a comparatively large and conspicuous nest. Several adults may feed the young, sometimes "queuing up" at the nest to do so. Evidence on this species' clutch size is conflicting, but the only certain record is of a single egg.



Cotinga eggs are typically buff, khaki or olive in ground colour, with spots or blotches of darker browns, sepia, ashy violet and similar colours, these often concentrated more thickly around the broad end. Almost certainly, the colour scheme is cryptic. The cocks-of-the-rock, the rock nests of which are often in semi-darkness, have eggs similar to those of other cotingids but with a paler ground colour. The eggs are unusually large for passerine birds; no obvious reason for this can be suggested, but it may be that the large egg size is related to the long incubation period, enabling the young bird to complete as much as possible of its growth in the egg. As already intimated, the clutch of almost all medium-sized and large cotingas consists of a single egg. The exception is the cocks-of-the-rock, which lay two eggs, as do the Andean fruiteaters. The Swallow-tailed Cotinga and, so far as they are known, the high-Andean *Ampelion* cotingas and related genera lay two or three eggs, whereas the clutch size of the plantcutters is 2-4 eggs. An old report claiming that the Rufous-tailed Plantcutter lays as many as five or six eggs appears unsubstantiated, and is deemed hardly likely to be true.

For all cotingid species for which the nesting habits are known, with the possible exception of the Swallow-tailed Cotinga, only the female incubates. Knowledge of the incubation and fledging periods is very incomplete. Compared with those of oscine passerines, the incubation periods of most cotingids are very long: 26-28 days for the Capuchinbird and the cocks-of-the-rock, 25-26 days for the Rufous Piha, 25 days for the Purple-throated Fruitcrow, 23 days for the Bearded Bellbird, and 17-20 days for two of the Andean fruiteaters breeding in captivity. The few fledging periods accurately documented are also comparatively protracted. Young of the two cocks-of-the-rock remain in the nest for up to 48 days, the corresponding period for the Purple-throated and Red-ruffed Fruitcrows and the Bearded Bellbird being 30-33 days, and for the Rufous Piha 28 or 29 days. At the single nest of the Sharpbill studied, the two chicks fledged after 25-30 days. The plantcutters have a more "normal" strategy, with incubation lasting for about two weeks and the chicks fledging after 17 days or so.

In the case of the fruiteaters and the high-Andean cotingas, the Swallow-tailed Cotinga and the group-nesting Purple-throated Fruitcrow, both male and female feed the nestlings. Similarly, the male Rufous-tailed Plantcutter also assists his partner in the rearing of the chicks. For all other cotingids for which the breeding habits are known, the female alone feeds and cares for the young.

Cotingid nestlings, like the adults, are unusually diverse in appearance. Except for the cocks-of-the-rock, in which the nest-

*Between March and June, this male **Bare-necked Umbrellabird** attends a lek in the highlands of Costa Rica. The top photograph shows him installed on a branch in the middle storey, resting between bouts of calling. From this perch, every minute or so, he gives a deep double-barrelled boom. In preparation for this vocal activity, he inflates the air-sacs housed in his throat, and his bare red-skinned wattle expands. Then he leans forward and extends the frontal crest even further forward so that it entirely covers the bill. When standing in this position, he expels air from his lungs, as shown in the lower photograph. This produces a deep booming noise, which is given extra resonance by the air-filled sacs. In addition, the booms of males are often accompanied by dry hacking sounds. Females visit these leks singly to copulate with the dominant male.*

[*Cephalopterus glabricollis*, Costa Rica. Photos: Michael & Patricia Fogden]

*Some male birds have no parental input other than sperm. When a female invests so much in nesting, incubation, provisioning and post-fledging care, it pays her to choose the father of her offspring very carefully. In some species, such as the **Andean Cock-of-the-rock**, this has led to the evolution of leks. Leks are permanent display arenas at traditional sites, where groups of males compete amongst each other for central positions. Young males start at the edge of the lek, and gradually move inward as they climb the hierarchy. By mating with the central male, the female saves a lot of time assessing prospective partners, and ensures that the genes passed on to her offspring are of the highest quality.*

[*Rupicola peruvianus saturatus*, Peru. Photo: Jean Paul Chatagnon/Bios]

ling's down feathers are long but sparse, they are thickly covered with down. Although it is not possible to give a comprehensive account, it seems that some, at least, of their diversity involves camouflage, thus varying according to the circumstances of the nest-site. The nestling of the Elegant Mourner is one of the most remarkable, being apparently camouflaged to resemble moss covered with fruiting bodies; its long filamentous down feathers are black or brown basally and conspicuously white-tipped. The nestling Bare-necked Fruitcrow bears an extraordinary resemblance to lichen, an appropriate camouflage as the nest is a small pad on a thick tree branch. B. K. Snow described the newly hatched nestling of a Bearded Bellbird as "thickly covered with grey-white hair-like down about 10 mm in length"; during the first twelve days, the chick, when disturbed or handled at the nest, "would roll up into a ball so that from above neither eyes, beak nor legs were visible, making it look more like a small mammal or hairy caterpillar than a nestling". Two striking cases of camouflage exhibited by the chicks of two globally threatened south-east Brazilian cotingas have been described by E. O. Willis and Y. Oniki. The nearly full-grown nestling of a Buff-throated Purpletuft, on its tiny exposed nest high in a bare treetop, grizzled grey above and barred with dusky on its pale chest, resembled both in colour and in the irregularity of its dorsal plumage "a scaly mass of bark or a bulky mass of debris on the flattened nest". In the second example, a small nestling Cinnamon-vented Piha, covered with orange down, lay "flat and fuzzy on the nest, seeming a hairy caterpillar or leaf, most of the day. The down was pale orange, and rather conspicuous in any sun-fleck, probably a mimic of hairy and urticating caterpillars." The thick down of these nestlings may also be associated with the fact that they are brooded by the parent very little after the first few days, so that efficient heat conservation may be especially important for them.

Everything that happens at the nests of these cotingas is silent, and movement is reduced to a minimum. When the female Bearded Bellbird comes to feed her nestling, she flies in swiftly and silently, lands on a perch near the nest, and remains motionless for a minute or so, evidently checking that no danger threatens, before hopping on to the nest. The parent Cinnamon-vented Piha makes an even more cautious approach to its nest, often stopping and perching motionless for minutes on end before going to it. The young chicks of both species beg for food merely by raising the head and gaping. It is very evident that the nest, the nestling, and the behaviour of parent and young are all highly adapted so as to avoid detection by nest-predators. In this connection, the behaviour of the parents at the recently discovered nest of the Black-faced Cotinga is somewhat puzzling. Both parents tended and fed the young in a tiny nest high in a treetop, and often vocalized loudly while doing so. It would be interesting to know whether Black-faced Cotingas can effectively defend their nests against potential predators, as do Purple-throated Fruitcrows.

A curious and unexplained habit is exhibited by some of the cotingas that build very small nests. This involves the dismantling and scattering of the materials of their empty nests shortly after the end of their use, such behaviour having been recorded for the Blue Cotinga (*Cotinga nattereri*), the Lovely Cotinga and the Rufous Piha. The material is not used for a new nest, and it seems most unlikely that such tiny nests would form a "search image" for potential predators and thereby endanger future nests built in the vicinity. The reason for this unusual behaviour remains a mystery.

So few cotinga nests have been studied that, with one exception, no reliable data exist on the breeding success of the members of the family; equally, nothing can be stated with regard to post-fledging parental care or the survival of young birds. The exception is the Guianan Cock-of-the-rock. In one year, only two of a total of 22 nests of this species produced fledged young, and only ten out of 31 did so in the next year, giving success rates of, respectively, 9·1% and 32·3%. The low success in the first year was thought to be perhaps atypical, being the result of unusual weather conditions. Otherwise, of five Bearded Bellbird nests in which eggs were laid, only one was successful; three of the losses were probably due to predation and one, in the most exposed site, to destruction of the nest by wind.

The age of sexual maturity is not known for any of the Cotingidae. In the case of males, it is not necessarily the same as the age of acquiring fully adult plumage or, in the lek-mating species, the age at which successful copulation is achieved. As already mentioned, it is usual that only one or a few dominant individuals succeed in mating. Males of the Guianan Cock-of-

*Plumage maturation in the male **Andean Cock-of-the-rock** is delayed. He retains brown or patchy plumage for three years, after which he is fully adult. Thenceforth, he holds a territory at the lek, and spends much of the day resting or displaying 2-6 m above the ground. He uses one perch, or a set of perches, keeping these bare by plucking leaves with the bill and claws. Displaying males are often loosely distributed in pairs, and greet one another in ritualized fashion. This involves much jumping, bowing, head-bobbing, wing-flapping, bill-snapping and the production of a strange nasal moaning call. The logic of the lek is founded on a winner-take-all philosophy: males in the middle get lots of matings, males at the edge get none. Not surprisingly, central positions are fiercely contested, and disputes over court ownership are often violent and prolonged.*

[*Rupicola peruvianus sanguinolentus*, west Andes of Ecuador. Photos: Günter Ziesler]

*The female **Andean Cock-of-the-rock** is a dowdy bird. She has dark legs, chocolate-coloured plumage, and a much reduced crest. Despite her sombre garb, the gathered contestants become animated when she approaches the lek. Confronted by an audience of gaudy and enthusiastic males, she always looks tremendously uninspired. The males redouble their efforts. They posture frantically, and produce a lot of noise. She tends to pass from court to court, focusing entirely on central positions, sizing up the occupants. Sometimes she passes through the lek for several days before choosing a particular male. When she perches beside him, he responds by bowing low and motionless, and by calling. Eventually, she signals her choice by nibbling at his feathers. Taking this as his cue, he hops onto her back, grabbing her wings for balance, and they copulate. Thus ends the male's involvement in family life: the female disappears into the forest to lay her eggs and raise her chicks alone.*

[*Rupicola peruvianus saturatus*.
Manu National Park and Biosphere Reserve, Peru.
Photos: Manfred Pfefferle]

*A few cotingids, including fruiteaters, purpletufts and plantcutters, are pair-living birds. Thus, unlike many of its lekking relatives, the male **Rufous-tailed Plantcutter** shares parental duties with his mate. He is seen here collecting nesting material, and he will later contribute to the feeding of nestlings. Most small cotingids build miniature nests out of pieces of lichen, or wiry bits of rootlet. They are never seen carrying anything bigger than fragments of vegetation. Plantcutters, as this male demonstrates, are fond of considerably bulkier material.*

[*Phytotoma rara*, Puerto Saavedra, Arauco, Chile. Photo: Andy & Gill Swash]

the-rock acquire fully adult plumage at the age of three years, and at that age begin to hold courts at the lek and so have the opportunity to mate.

Movements

Many cotinga species are, so far as is known, sedentary. There is undoubtedly some dispersal of young birds, but no detailed information is available. Only one of the typical cotingids, the Swallow-tailed Cotinga of east Brazil, is known to carry out seasonal north-south movements, being present in the extreme south of its range, in Rio Grande do Sul, only in the austral spring and summer, between late September and late March. Farther north, in the main part of its range, it breeds in the mountains and descends to lower levels in winter.

The Rufous-tailed and White-tipped Plantcutters, which breed farther south than any other members of the family, are generally resident, but the southernmost populations, as well as those breeding at higher elevations, are at least partially migratory. These wander outside the breeding season, and some probably move northwards. Indeed, it seems likely that most Rufous-tailed Plantcutters in the southern parts of Chile and Argentina migrate after breeding. Records of White-tipped Plantcutters in Brazil and Uruguay probably involve migrants.

Seasonal altitudinal movements are made by a number of other cotingas, including the Three-wattled Bellbird and the Bare-necked Umbrellabird in Central America, and the Bare-throated Bellbird in Paraguay and east Brazil. The Three-wattled Bellbird's movements are the most striking so far known. After breeding at elevations above 1200 m, it initially moves up to higher levels, before descending to sea-level, and has been recorded on islands off the south coast of Panama. A recent study, involving a programme of radio-tagging, has demonstrated that individuals from the highlands of north Costa Rica move first to lowlands in south-east Nicaragua, and then to Pacific coastal areas of south-west Costa Rica. Bare-necked Umbrellabirds breed locally in subtropical forest at 800-2000 m in Costa Rica and west Panama. A recent study of this species in the Monteverde Forest Reserve, in Costa Rica, revealed that the birds left the breeding areas in late July and August and moved down to the lowlands, returning to the breeding grounds in March; interestingly, the majority of males spent the non-breeding season at elevations of 100-500 m, whereas most females were found below 200 m at that time of the year. There is some evidence that the Bare-throated Bellbird may even be migratory, at least in part, in south-east Brazil and adjacent Paraguay, and records of the species from Argentina suggest that it may be only a transient visitor there.

From the little evidence available, the Buff-throated Purpletuft in south-east Brazil appears to be highly unusual in that it breeds in the coastal lowlands in the austral late winter and moves up into the highlands in the off-season. Breeding records of this species cover the period from July to October, and at other times of the year individuals have been observed at higher elevations.

Less regular movements are reported for a number of cotingids, and the nature of these is as yet unclear. It seems probable that some of the species inhabiting lowland forest of Amazonia and the Guianas may wander widely, presumably following the ripening of the fruits on which they depend (see Food and Feeding), and this may also be the reason for the apparently wide, unpredictable wandering of the white cotingas in Central America. Neither this factor nor juvenile dispersal, however, seems an adequate explanation for the occasional very long movements made by single White Bellbirds, including adult males, which have been recorded several hundred kilometres away from their normal range, north to Trinidad and south in Brazil to the middle and lower Rio Negro. The definite Trinidad

*The nests of plantcutters are simple, dish-like structures. They are usually placed low in dense, thorny cover, this concealment and inaccessibility offering some defence against predation. The nest of the **White-tipped Plantcutter** is surprisingly large for the size of the bird (4·5-10 cm high, 10-17 cm across), and is lined with softer material, such as root fibres.*

[*Phytotoma rutila rutlia*, Tucumán, Argentina. Photo: José & Adriana Calo]

*The only nest of the **Bare-necked Umbrellabird** ever to be reported was a large structure of twigs, leaves and moss, situated about five metres above the ground. It was far larger and bulkier than the nests of any other cotingid yet recorded. It contained a single egg which was incubated for at least 24 days. Umbrellabirds have the biggest nests amongst cotingids, while many other species in the family build miniature structures. Indeed, relative to their own size, some cotingas make the smallest nests of any passerine birds.*

[*Cephalopterus glabricollis*, Costa Rica. Photo: Michael & Patricia Fogden]

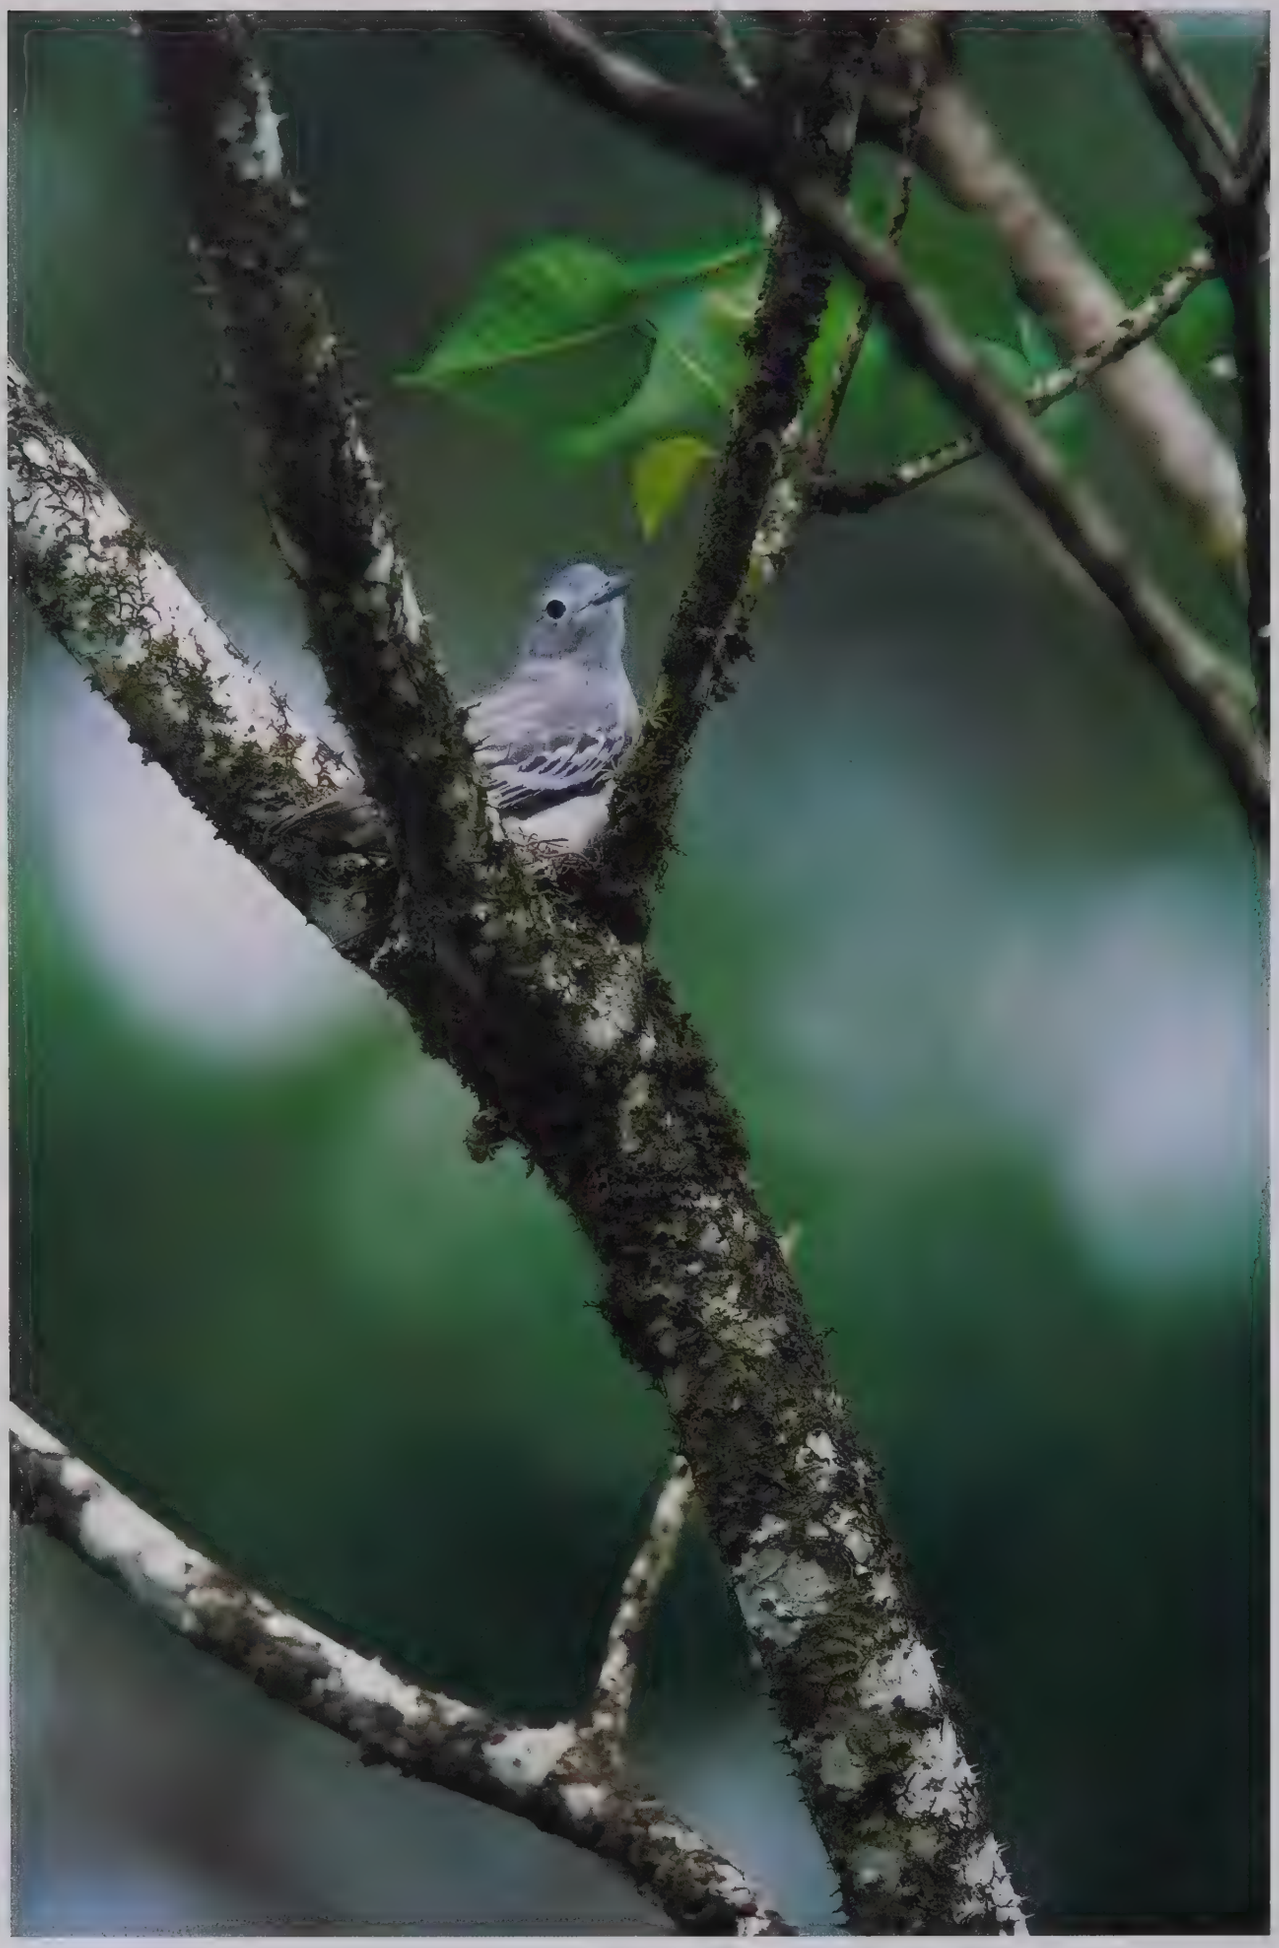
records, of which there are at least six, are all of males, but this is not surprising, as the inconspicuous females would be difficult both to detect and to distinguish from the resident Bearded Bellbird females. It may be that such birds are potential pioneers, and that a tendency to move long distances away from the established range is an important facet of the behaviour of bellbirds, and of other species with limited montane breeding areas, as a means of establishing new breeding populations. The recently discovered population of White Bellbirds in the Serra dos Carajás, in central Brazil, may be an example of such a successful pioneering movement in the fairly recent past. More speculatively, the Three-wattled Bellbird of Central America, the White Bellbird's closest relative, probably originated from long-distance dispersal of White Bellbird stock from the Guianan highlands in the more remote past. The small population of Swallow-tailed Cotingas in the foothills of the Bolivian Andes, some 1200 km from the species' main range, in south-east Brazil, may have a similar origin.

Relationship with Man

Before the era of scientific collecting, humans apparently took little notice of most of the cotingas. Only the brilliant male plumage of some of the species drew attention. H. Sick, for example, has recorded that the Emperor of Brazil had a mantle made of cock-of-the-rock feathers, and that various indigenous tribes used brilliant cotinga feathers in their costumes, those of the Plum-throated Cotinga being especially prized. Similarly, male Banded Cotingas were once collected by local Indians and Bahian nuns, who used the birds' feathers in order to make artificial flowers. Today, there is still limited collecting of spectacular male cotingas, which are roughly prepared, as flattened skins, for the tourist trade. This probably has relatively little impact on cotingid populations, but it could become a cause for concern in the case of species with low population levels or declining numbers, of which the Banded Cotinga is one example (see Status and Conservation).

Sick also noted that various species are considered by local people to be "gamebirds". Somewhat unexpectedly, in addition to the large Red-ruffed Fruitcrow, considerably smaller birds such as the Swallow-tailed Cotinga, the Black-and-gold Cotinga and the blue cotingas are all taken for food. Hunting would probably not be a great threat to the populations of these species, so long as they retain adequate extents of suitable habitat, but hunting for food is now considered to be one of the threats to the survival of the Long-wattled Umbrellabird (*Cephalopterus penduliger*), a Vulnerable cotingid already greatly reduced in numbers by the destruction of trans-Andean forests (see Status and Conservation).

In Brazil, the Bare-throated Bellbird is widely kept as a cagebird, and trapping must have some impact on the adult male population of this Near-threatened species (see Status and Conservation). Its social system, however, involving competition among males for mating perches (see Breeding), should enable it to withstand the removal of some males from the population. It seems rather surprising that this is the only cotingid that is widely kept as a pet. Visitors to Brazil must often wonder at the popularity of a bird that utters a succession of ear-splitting, unmusical hammer-like notes from a small cage hung near a house door.



Because of their wonderful plumage colours, many cotingids are popular as cagebirds in other parts of the world, such as Europe. As they are essentially frugivorous (see Food and Feeding), they are relatively easy to keep in captivity.

Instances of conflict between cotingids and human interests are rare. Indeed, in the case of most members of the family they are non-existent. Only the plantcutters have any adverse impact. Because they are primarily herbivorous, feeding on leaves, buds and shoots, plantcutters can present problems not only to private gardeners, but also to commercial crop-growers. In some parts of its range, therefore, the Rufous-tailed Plantcutter is often considered an agricultural pest. It appears to have a clear preference

The nominate race of the ***Swallow-tailed Cotinga*** *is a bird of cloudforest edges and patchily forested hillsides in south-east Brazil, although it has been found in tiny numbers in Argentina and Paraguay. Like many other canopy-dwelling cotingids, it builds a small, inconspicuous nest in a bare fork. It uses lichen for most of the structure, a material which adds greatly to the nest's camouflage on lichen-encrusted branches. Interestingly, it is the only member of the family for which male incubation has been reported (this photograph shows a female). It differs from most of its relatives in favouring scattered trees at forest margins, in clearings or even in gardens. Because of this preference for isolated trees, nests have proved relatively easy to find around hotels in Itatiaia National Park, and near the research station buildings in Intervales State Park. The Swallow-tailed Cotinga is highly distinctive in both morphology and behaviour. Its pale bill and strongly barred underparts are unusual, but its long forked tail is unique in the family, and may be an adaptation to its foraging technique of sallying after flying insects above the treetops. Given its relatively small population, and its dependence on shrinking montane forests, it is classed as Near-threatened. Recently, after an absence of almost 100 years, the population in north Bolivia was rediscovered. This isolated race,* boliviana, *differs from the nominate in a range of relatively minor morphological features, but it is suggested that it may deserve treatment as a separate species.*

[*Phibalura flavirostris flavirostris*, Intervales, São Paulo, Brazil. Photo: Edson Endrigo]

The smallest nests in the family are built by members of high-canopy genera, such as Cotinga, Xipholena, Conioptilon, Iodopleura *and* Carpodectes. *These groups build small shallow saucers, or tiny cup nests, in the forks of branches. The nests are usually loosely woven with a few wiry tendrils or narrow twigs, as can be seen in this photograph. As well as being incredibly inconspicuous by virtue of their tiny size, such small, loosely bound nests must be less susceptible to waterlogging in heavy rainfall. This female* ***Snowy Cotinga*** *hardly looks like she is incubating at all, and in precisely this manner she succeeds in drawing less attention to her egg or nestling. The nest is so small in this species, and many other canopy-nesting cotingids, that the clutch is limited to a single egg. The genus* Carpodectes *is allied to* Cotinga *and* Xipholena, *and like them its members range through the forest canopy eating fruit. The females of all three species are greyish and almost dove-like, but the males are brilliantly, almost luminously, white. The latter are visible from considerable range, as they perch atop dead snags over the canopy.*

[*Carpodectes nitidus*, La Selva Biological Reserve, Costa Rica. Photo: Marco Saborío]

*The **Guianan Cock-of-the-rock** differs from all other members of the family, apart from its sole congener, in having its nest fixed to a rock face rather than a tree. The nest itself is usually a bracket-shaped structure built from mud and vegetable matter, and most often placed in a dark crevice. In this case, the nest is not a bracket, but a platform built on top of a convenient ledge. Saliva is probably used to cement the nest material together, and to attach the structure to the rock. The female incubates the one or two eggs for about 28 days, which is a very long incubation period for a bird of this size.*

[*Rupicola rupicola*, Iwokrama Forest Reserve, Guyana. Photo: Pete Oxford/DRK]

for the young leaves of cereal crops, in addition to which it sometimes causes damage locally in gardens and fruit orchards.

Status and Conservation

Of the 71 species included in Cotingidae (see Systematics), as many as 16 are currently classified as globally threatened. In addition, the nominate race of the Elegant Mourner, often treated as a full species, distinct from the three Andean subspecies, is listed as globally threatened. Of this total of 17 threatened taxa, eight are from the Atlantic Forest of eastern South America, the destruction of which in the lowlands has long been a source of major concern to conservationists, and four are from Central American forests, which have suffered equally severe, if less extensive, destruction. Of the remaining five, two live in high-Andean temperate woodland, a habitat in danger of being destroyed by marginal farming activity, and another, the Scimitar-winged Piha, inhabits humid subtropical forest in the Bolivian Andes, where its fragmented habitat is subjected to continued clearance and degradation. Finally, the spectacular Long-wattled Umbrellabird is confined to the severely reduced trans-Andean forests of Colombia and Ecuador, and the Peruvian Plantcutter inhabits surviving areas of low woodland, riparian thickets and desert scrub in coastal north-west Peru.

One of these globally threatened species, the Kinglet Calyptura, is classed as Critical. Five others are Endangered, while ten species are listed as Vulnerable. The nominate subspecies of the Elegant Mourner is also placed in this last category.

All of the threatened cotingids have suffered from serious habitat loss and degradation, which continues to be a major problem for them; a few are under additional pressure from hunting and/or collecting for the cagebird trade. A further five species, having suffered similar habitat loss, are currently classified as Near-threatened. These are the Swallow-tailed Cotinga, the Black-and-gold Cotinga, the Hooded Berryeater (*Carpornis cucullata*), the Fiery-throated Fruiteater (*Pipreola chlorolepidota*) and the Bare-throated Bellbird. Four of these are from south-east Brazil, one of them, the Bare-throated Bellbird, also extending west into Paraguay. The fifth, the Fiery-throated Fruiteater, inhabits humid forest in the Andean foothills, ranging from south Colombia south to central Peru.

Thus, 21 members of the family, or 30%, either are already at risk or could soon become so, and one additional subspecies is threatened. Moreover, the rather distinctive Bolivian subspecies of the Swallow-tailed Cotinga, rediscovered in 2000, almost a century after its original discovery, is apparently confined to a restricted area of open forest and humid forest fragments around the town of Apolo, in central La Paz; part of the area, which may be as small as 50,000 ha, is within the Madidi National Park, providing some protection for the taxon. If *boliviana* is recognized as a distinct species, it should be considered globally threatened.

None of the cotingas of the lowland Amazonian and Guianan forests is at present considered threatened. This is due to their generally having extensive ranges, and to the fact that, despite the recent devastation in many areas, much forest remains.

Deforestation seems almost certainly to have been responsible for the disappearance of the Kinglet Calyptura. It had not been recorded for over a century, and was presumed by many ornithologists to be extinct. In October 1996, however, it was rediscovered by a remarkably keen-eyed observer, R. Parrini, at 550 m on the edge of the Serra dos Órgãos National Park, some 60 km north of the city of Rio de Janeiro. Two individuals were observed on several occasions during 27th-30th October, but, in spite of intense and repeated searching, no further sightings of this tiny, inconspicuous species have been made. The fact that there are about 50 specimens of this cotingid in museum collections, the last one dated around 1890, suggests that it was not uncommon 150 years ago. Since that time, virtually all forest below 1000 m in the area has been destroyed. It is to be hoped that intensive surveys will lead to the calyptura being refound. In any event, conservation of the remaining lowland forest in the vicinity of the 1996 sightings must surely be considered a priority measure.

Elsewhere in eastern Brazil, the Grey-winged Cotinga is also restricted to the Rio de Janeiro vicinity, where it is present in small numbers in Serra dos Órgãos National Park and the Tinguá Biological Reserve. In both areas disturbance and fires are potential threats, and the species is listed as Vulnerable. Two others placed in this threat category are the Black-headed Berryeater (*Carpornis melanocephala*) and the Cinnamon-vented Piha. The former, found primarily in 13 protected areas in Alagoas and from Bahia south to São Paulo and Paraná, is fairly common locally, but has declined significantly. The piha occurs from Bahia, Mi-

Very different from the tiny, exposed nest of the ***Bearded Bellbird*** *in Trinidad, this female of the slightly different race from north-east Brazil has built a comparatively bulky stick platform in dense cover. Unlike the spectacular male bellbirds, females are well camouflaged against a background of branches and foliage. This is an important adaptation as the total nesting cycle is very long for birds of this size. Incubation in the Bearded Bellbird lasts 23 days, and the nestling fledges some 30-33 days later. The chick is covered in dense, 10-mm-long grey-white down. It rolls up when disturbed so that bill, eyes and legs are invisible. It has been suggested that this plumage and behaviour has evolved to mimic urticating caterpillars, which most predators avoid. In addition, the chicks are rarely brooded after hatching, and thus the thick down probably functions as vital insulation. The provisioning process in this species, as with most in the family, is swift and silent, stealth being the key to minimizing predation. After landing near the nest, the female waits for a moment to check that all is clear, and then hops onto the nest, feeds her offspring, and flies off. The chick too is apparently silent throughout this sequence of events, so as not to attract attention.*

[*Procnias averano averano*, Maranhão, Brazil. Photos: Anita Studer]

Swallow-tailed Cotinga *nestlings are covered in dappled down. This aids against potential predation, as they look just like a small mat of lichen when they crouch still. Mimicry of lichen is prevalent in those canopy species that choose nest-sites in the fork of high branches. Most cotingas of this type lay one egg due to constraints of space, but the Swallow-tailed Cotinga nests in trees so rich in epiphytic bryophytes and lichens that it can afford to build a larger structure holding 2-3 eggs. As in high-Andean cotingids, and the Purple-throated Fruitcrow* (Querula purpurata)*, there is biparental care. Here a stunningly beautiful male feeds his offspring.*

[*Phibalura flavirostris flavirostris*, Intervales, São Paulo, Brazil. Photo: Edson Endrigo]

nas Gerais and Espírito Santo south to Santa Catarina, but has become rare, with recent records from perhaps a dozen or so sites; its population, now highly fragmented, seems to be strongest in the Augusto Ruschi Biological Reserve, in Espirito Santo, where a few thousands of individuals occur. Likewise, increasing deforestation and habitat fragmentation have led to a decline in the numbers of the nominate race of the Elegant Mourner, which is now rare; it occurs in more than ten reserves, but effective protection of these areas is rarely guaranteed.

Three cotingids in this region come under the high-risk category of Endangered. The Buff-throated Purpletuft is confined to very few sites in north-east Brazil and just a few more from Bahia south to São Paulo, and is clearly threatened in both parts of its range by loss of Atlantic Forest; the fact that it occurs in mainly lowland coastal forest renders it much more at risk than was previously thought, as this habitat is being rapidly cleared. Similarly, the White-winged Cotinga, with an estimated total population of the order of 12,000-13,000 individuals confined

Although this female ***Andean Cock-of-the-rock*** *is regurgitating a meal of berries, she often feeds her nestlings with insects and even small vertebrates, such as reptiles and amphibians. These are beaten against branches and offered head-first to the young. At some nests the chicks are fed almost entirely on insects and other animal prey, a diet which presumably provides the proteins necessary for growth. Despite this, the fledging period in cocks-of-the-rock is very long, lasting up to 48 days. Fledging success seems quite low, probably in the region of 10-30%, perhaps because nests are susceptible to discovery.*

[*Rupicola peruvianus*, Peru. Photo: Kevin Schafer]

Being so strictly tied to forests, most members of Cotingidae are affected by deforestation, the rampant environmental scourge of South and Central America. The diminutive ***Fiery-throated Fruiteater,*** *for example, lives in the Andean foothills from south Colombia to central Peru, a region where natural habitat is relentlessly being replaced by agricultural land, pasture, roads and settlements. There is still enough suitable forest to suggest that its population is too large to fit the criteria delimiting threatened-species categories. On the basis of habitat loss it is placed in a holding bay for species that might soon meet those criteria: the Near-threatened category. In part, its inclusion in this category is based on the fact that we know so very little about it. It is the smallest member of its genus, a bird of unobtrusive vocalizations and retiring habits in the dense lower and middle growth of forests. These features do not lend it to easy observation. Its numbers are possibly much higher than records suggest, but until this can be confirmed through detailed surveys and mist-netting at a range of sites it certainly merits close attention.*

[*Pipreola chlorolepidota*, San Diego Zoo, USA. Photo: Josep del Hoyo/ Lynx Edicions]

*Like all its congeners, the male **Turquoise Cotinga** is a stunning sight when seen at close range. This species is restricted to Costa Rica and Panama, where it lives in humid forest and secondary woodland from the lowlands up to 1850 m. Unfortunately, it is thought to be in steep decline due to the steady destruction and fragmentation of these habitats. This has led to its recent inclusion in the list of Threatened birds, with the category of Vulnerable. Despite a relatively healthy prognosis for conservation in Costa Rica, large swathes of humid forest have been removed in recent years, and many species are at risk until this loss of habitat can be stalled, and reversed.*

[*Cotinga ridgwayi*, Las Cruces, Costa Rica. Photo: Kevin Zimmer]

more or less to 13 protected areas along the coast from Paraíba south to Rio de Janeiro, has lost 60% or more of its Atlantic Forest habitat since 1980. As is so often the case, inadequate law enforcement in protected areas is a big problem facing many bird species, including this cotingid, and fires, as well as illegal logging and other activities, are a constant potential threat. Bearing this in mind, the situation of the Banded Cotinga is even more worrying. This species has a very small range, covering about 780 km² in south-east Bahia and north Espírito Santo, and a global population of fewer than 1000 individuals, almost all now confined to four nominally protected reserves. It was often collected for the cagebird market, but is now seen with far less frequency in this trade, no doubt because it has become very much rarer.

On the opposite side of South America, the population of the Peruvian Plantcutter has now been reduced to a similarly low level, so that it, too, is Endangered. In the past, small populations of this interesting species were known to occur at a minumum of 14 localities, covering most of coastal north-west Peru south to Lima, but its range has become very small and severely fragmented. Since the late 1990s, there are records from only eight locations, and the plantcutter is absent from much apparently suitable habitat. About 80% of its world population is found in the department of Piura, where an estimated 50,000 ha of habitat in the Talara region, from Quebrada Salada to Quebrada Ancha and south to Cerro Negro, holds between 500 and 1000 individuals. The Peruvian conservation organization *ProAvesPerú* is collaborating with the national petrol company *PetroPerú*, which owns most of the remaining habitat, and the National Audubon Society with the aim of declaring a 10,000-ha area as a reserve; in addition, it has initiated a public-awareness programme, with the cartoon character "Coco the Plantcutter" as the star figure. The remaining sites where the species survives are small forest fragments around Chiclayo, in Lambayeque department, each of which covers only a few hundred hectares and holds 20-40 individuals; more recent observations have been made near Trujillo, in La Libertad, and as far north as Mancora, in north-west Piura. It is of major concern that all forests in which the Peruvian Plantcutter has been found are threatened by burning, goat grazing, felling for timber, extraction for firewood and charcoal, and conversion to sugar-cane fields and other forms of cultivation, the same factors that presumably destroyed the historical sites. In Lambayeque, a considerable proportion of habitat close to Rafan is degraded, and parts of this area were converted to sugar production in the 1990s; Murales forest is an Archeological Reserved Zone and strict wardening has maintained the habitat, but land rights to part of the forest were sold for agricultural conversion in 1999, and government intervention was necessary to prevent further sales of land for agriculture. Given these numerous and immediate threats, which typify the problems facing conservationists in the modern world, the Peruvian Plantcutter should probably be returned to the threat category in which it was classified until the year 2000, that of Critical.

The Pacific slope of the Andes is also home to the Long-wattled Umbrellabird. This most striking of cotingids lives in humid forest in south-west Colombia and west Ecuador, where it has been recorded at elevations ranging from 140 m up to 1800 m. Since 1960, extensive areas of forest have been destroyed in this region, especially in the lowlands, and the species has become, for the most part, rare and local. Intensive agricultural development is considered a major threat. Road-building has opened up more and more previously remote areas, leading to further habitat destruction and facilitating the hunting of the umbrellabird, which is often killed for food. In addition, this species may suffer through being collected for the bird trade. As a result of these factors, its population is probably declining at a fast rate, and it is considered Vulnerable.

Higher up in the Andes, three restricted-range cotingids have suffered from clearance and degradation of their forest habitats to the point that they, too, are now placed in the category of Vulnerable. These are, from north to south, the Chestnut-bellied Cotinga (*Doliornis remseni*), occurring from Colombia south to extreme north Peru, the White-cheeked Cotinga, confined to the Peruvian Cordillera Occidental, and the Scimitar-winged Piha, which is found in the upper yungas of extreme south-east Peru and Bolivia. The first of these three was not discovered until 1989; it lives in dense thickets around the timber-line, at about 3100-3700 m, where it has been recorded from a handful of localities. The White-cheeked Cotinga is patchily distributed but locally common, although its global population, estimated at 1500-6000 individuals in 1992, is small; it inhabits mainly *Polylepis-Gynoxys* woodland at 2700-4250 m, where it apparently feeds on two species of mistletoe and is probably the main dispersal agent for them (see Food and Feeding). The third species, the Scimitar-winged Piha, has a very small total range, within which it has been found at only very

*The **Black-headed Berryeater** and the **Cinnamon-vented Piha** are restricted to the Atlantic Forest of Brazil. Neither species is on the verge of extinction, but they have both suffered huge losses due to deforestation in their restricted ranges, especially in the lowlands. Given this situation, they are treated as Vulnerable. The berryeater occurs from Alagoas to Paraná, and the piha occurs in a slightly smaller range, from Minas Gerais to Santa Catarina. Both have become scarce overall; they are susceptible to local extinction because they occur in forests at low or moderate elevations, and these are much more prone to clearance than are montane forests. The berryeater has its stronghold in two crucially important reserves: Sooretama and Linhares. These blocks of forest stand in a low-lying region otherwise almost wholly cleared of natural habitat. The piha is absent from these lowland sites, occurring at slightly higher altitude in the foothills and lower montane zone. Its stronghold probably lies in another protected area, the Augusto Ruschi Biological Reserve (Nova Lombardia), where a few thousand individuals are thought to survive. Effective protection of these three sites, all of which lie in the state of Espirito Santo, would help to ensure a safe future for these rare cotingids.*

[Above: *Carpornis melanocephala*, Juréia, São Paulo, Brazil.

Below: *Lipaugus lanioides*, Intervales, São Paulo, Brazil.

*The **Buff-throated Purpletuft** is classified as Endangered. It occurs at very few sites in north-east Brazil, and a few more further south, from Bahia to São Paulo. It breeds at low altitude and spends the summer at higher elevations, a reversal of the migratory pattern found in most of the region's birds. Because of these altitudinal movements, it needs more habitat than a sedentary species in order to survive. In particular, its predilection for lowland breeding habitat places it in danger of extinction, given the severe degradation and fragmentation of lowland forest in coastal Brazil.*

[*Iodopleura pipra ieucopygia*, Boa Nova, Bahia, Brazil. Photo: Edson Endrigo]

few localities, all in montane forest at 1800-2750 m; if it requires old-growth forest during at least part of the year, as has been suggested, this would render it more susceptible than other yungas species to the effects of selective and small-scale logging.

Of the four globally threatened cotingids of Central America, the one considered to be at greatest risk is the Yellow-billed Cotinga. This rather specialized member of the family survives in a few places on the Pacific coast of Costa Rica and extreme west Panama. It inhabits mangroves, a habitat that has been extensively destroyed on a global scale, and it also occurs in adjacent areas of lowland forest and scrub, most of which have likewise been eliminated. This cotinga, reduced to the brink of extinction in Panama and with a small and declining population remaining in Costa Rica, is now listed as Endangered. The Turquoise Cotinga is restricted to the same two countries, but lives in humid forest and secondary woodland at up to 1850 m; as a result of severe fragmentation of these habitats, this species is thought to be in rapid decline. Similarly, while the subtropical forest inhabited by the Bare-necked Umbrellabird in those countries remains sufficiently intact, much of the lowland forest in which this species spends the non-breeding season (see Movements) has been lost; in north Costa Rica, for example, 35% of the remaining lowland forest was removed in the period from 1986 to 1992, and the little habitat still left is under severe threat. This same factor has added to the pressures facing the Three-wattled Bellbird, which also moves down into the Central American lowlands after breeding. These last three cotingids are all classified as Vulnerable.

Particular mention must be made of one further cotingid, the Chestnut-capped Piha. The conservation status of this species has not been formally assessed, since it was not discovered until 1999 and was officially described two years later, in 2001. At that time, the piha appeared to be fairly common within a narrow belt of very humid premontane forest in the central range of the Colombian Andes, where it had been recorded at five localities. Continuing studies in 2002 led to the species being detected at a further 20 sites in the area, all within the elevational range of 1400-1900 m. Intensive observations by A. Cuervo revealed that, in small forest fragments, this newly discovered cotingid exhibited a high degree of morphological asymmetry, apparently related to lower survival rate, reduced fitness and poorer aerodynamics. This would indicate that it is one of the species most adversely affected by forest fragmention. In view of the current rate of forest clearance within the piha's exceptionally small known range, it is suggested that the species be given the conservation status of Endangered or, perhaps more fittingly, Critical. An important 320-ha forest block at the type locality, La Forzosa, which harbours populations of several other threatened bird species, has now been afforded formal protection, despite great adverse pressures. More complete investigation of the Chestnut-capped Piha's present range is desirable, and the establishment of additional protected areas in this ornithologically poorly known region is an urgent priority.

Finally, the role of protected areas in the conservation of threatened species needs to be considered. With the possible exception of the Kinglet Calyptura, all of the globally threatened cotingas have subpopulations, at least, occurring in reserves and other protected areas. While this should provide some reason for optimism, there is certainly no room for complacency. Protective legislation is all too frequently ignored, and illegal activities, including logging, burning and even large-scale clearance of vegetation, remain a widespread problem. As forest destruction continues at an increasingly alarming rate, the future survival of many threatened cotingas, as well as that of numerous other species, will depend on the effective maintenance of already existing forest reserves, together with the establishment of new ones of adequate size.

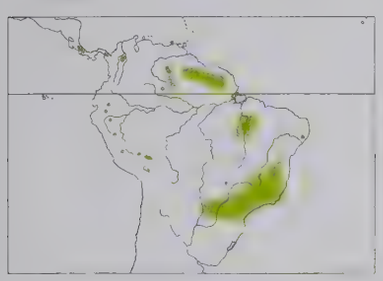
PLATE 1

inches 4
cm 10



Genus *OXYRUNCUS* Temminck, 1820

1. Sharpbill

Oxyruncus cristatus

French: Oxyrhynque huppé **German**: Flammenkopfkotinga **Spanish**: Picoagudo

Taxonomy. *Oxyrhyncus* [sic] *cristatus* Swainson, 1821, Brazil.
Often placed in a separate, monotypic family Oxyruncidae or, sometimes, in Tyrannidae, but DNA-DNA hybridization data indicate that it is related to other cotingids. Race *phelpsi* and *tocantinsi* possibly indistinguishable from *hypoglaucus*. Species' distribution extremely disjunct, perhaps relictual; individuals observed in NW Colombia, SE Ecuador, Peru, NW Bolivia and S & NE Brazil of uncertain racial identity, thought possibly to represent one or more undescribed races. Six subspecies recognized.
Subspecies and Distribution.
O. c. frater (P. L. Sclater & Salvin, 1868) - Costa Rica and W Panama (E to Veraguas).
O. c. brooksi Bangs & Barbour, 1922 - E Panama.
O. c. phelpsi Chapman 1939 - mountains of S & SE Venezuela (except Mt Roraima) and adjacent parts of Brazil and Guyana.
O. c. hypoglaucus (Salvin & Godman, 1883) - SE Venezuela (Mt Roraima), the Guianas and NE Brazil (Amapá).
O. c. tocantinsi Chapman 1939 - S Pará (from E side of lower R Tocantins SW to Serra dos Carajás, on W side), in Brazil.
O. c. cristatus Swainson, 1821 - SE Brazil (S Goiás, Minas Gerais and Espírito Santo S to Santa Catarina), E Paraguay and extreme NE Argentina (N Misiones).
Also occurs (subspecies undetermined) in NW Colombia (Serranía de San Lucas), SE Ecuador (Cordillera Cutucú, Cordillera del Condor), Peru (Junín, San Martín/Amazonas, Cordillera Azul, Cuzco, Puno), NW Bolivia (La Paz, R Tuichi) and S & NE Brazil (S Mato Grosso, Mato Grosso do Sul, Alagoas, S Bahia).

Descriptive notes. c. 17 cm; 42 g. Distinctive cotingid with sharply pointed bill and small head. Male nominate race has black crown mixed with olive, red erectile crest usually held flattened (thus concealed); upperparts olive-green, two indistinct pale yellow wingbars; outer primary with serrated leading edge; face and throat whitish with narrow black scaling; underparts yellow with heavy black spots, belly whiter; iris red; bill and legs greyish. Female differs from male in having crest reduced to narrow central line, iris orange, outer primary not serrated. Juvenile lacks red on crown. Races differ mainly in intensity of yellow wash below, also in slight variations in hue elsewhere: *frater* is paler yellow below than nominate; *brooksi* is yellowish-white below, the yellow paler and less extensive, reduced on breast and absent on foreneck, also lower back and rump slightly paler green than previous; *hypoglaucus* has throat and breast greyish-white, rest of underparts pale greenish-yellow, centre of belly cream-coloured; *phelpsi* resembles previous, mostly whitish below, little yellow cast; *tocantinsi* is very like last. VOICE. Male song exceptionally distinctive, an extremely firm, sharp whistle lasting 1-3 seconds, starts at frequency of c. 3 kHz and descends over wide interval (from a fourth to as much as a full octave), likened to sound of a falling bomb. Other described calls include weak "tet" and high tremulous "tsirrr", context in which given not known; also, weak descending chatter of 6-10 syllables heard during possible courtship.
Habitat. Humid tropical forest, usually at 400-1100 m, in Venezuela to 1200 m (Sierra de Lema); reported from lowlands, almost down to sea-level, in non-breeding season in Brazil (Pará).
Food and Feeding. Feeds on fruits, also invertebrates. Both large and small fruits eaten, include berries of various families (e.g. Ericaceae, Loranthaceae, Moraceae), also arillate fruits; in SE Brazil, fruits of 9 plant species (of 8 families) recorded as eaten. Invertebrates include caterpillars. When catching arthropods, may hop along high branches, probing into tufts of moss or epiphytes; also moves with great agility among leaves of outermost twigs of canopy, often hanging upside-down and making rapid pecks into bases of leaf clusters. Sharp, wide-based bill sometimes used as a wedge to pry open rolled leaves in order to extract concealed prey, similarly to open dehiscing fruit to extract seeds. Usually seen singly. Often associates with mixed-species flocks, particularly canopy flocks formed around tanagers (Thraupidae), and seems generally to join those that remain in same spot for lengthy period; reported also as following roving flocks, such behaviour presumably more likely outside breeding season.
Breeding. Singing period Feb-Jun in Costa Rica and Sept-Nov in SE Brazil, probably represents breeding season; nest found in Feb in Venezuela. Loose groups of 3-4 singing males, defending separate but adjoining territories each of c. 200 m in diameter, may represent "exploded" lek; singing male stretches neck forward and fluffs out neck feathers, but does not expose red crest. Nest a small open cup of petioles, covered with mosses, liverworts and spider web, the whole cemented with saliva, placed high in canopy. Clutch uncertain, probably 2 eggs; at one nest (SE Brazil), attended by only one adult, presumed female, incubation in shifts of c. 30 minutes, absences of c. 8 minutes, lasted 14-24 days, the two chicks fed by regurgitation, approximately one feed per hour early in nestling period, rising to two per hour in later stages, fledged after 25-30 days.
Movements. Minimal information. Probably sedentary; possibly some altitudinal movements, descending to lower levels outside breeding season.
Status and Conservation. Not globally threatened. Status difficult to determine, as species poorly known and very hard to observe. Appears to be fairly common, but often local; only few records from Argentina, all in Iguazú National Park. Distribution oddly fragmented, but no reason to suppose that this is other than natural. Racial affiliation of individuals recorded in humid upper tropical forest in E Peru (four sites), in Bolivia (SW of Apolo, in La Paz) and at isolated localities in Brazil (S Mato Grosso, Alagoas) requires investigation: in addition, discovered in 2001 in Colombia (Serranía de San Lucas, N end of C Andes); was also reported from S Ecuador (S Zamora-Chinchipe) in Jul 1993, but details lost. Because this species inhabits montane forest, it is less at risk of habitat loss than are those species occupying lowland forest and, although poorly known, it is not of immediate conservation concern; indeed, there is some evidence of range expansion in the mountains of SE Brazil.
Bibliography. Blake (1950), Brooke *et al.* (1983), Brooks *et al.* (1993), Chapman (1931, 1939), Chebez (1994), Chebez *et al.* (1999), Davis (1986), Dubs (1992), Eisenmann (1955), Finch, D.W. Genus *PHYTOTOMA* Molina, 1782

2. Peruvian Plantcutter

Phytotoma raimondii

French: Rara du Pérou **German**: Graubrust-Pflanzenmäher **Spanish**: Cortarramas Peruano

Taxonomy. *Phytotoma raimondii* Taczanowski, 1883, Tumbes, Peru.
Genus formerly treated as constituting a separate family of uncertain affinities or, sometimes, as a subfamily within Tyrannidae; more recent genetic data, however, indicate close relationship, possibly as sister-group, to a cotingid clade formed by the genera *Ampelion*, *Doliornis* and *Zaratornis*. Forms superspecies with *P. rutila*. Monotypic.
Distribution. Coastal NW Peru (Tumbes very locally S to La Libertad).

Descriptive notes. 18·5 cm; 36-44 g. Distinctive, with short but expressive crest, pale eyes, short, conical bill with finely serrated edges. Male has cinnamon-rufous spot above bill; rest of head and upperparts dull ash-grey, some striping on crown and back; wings blackish, whitish lesser and median wing-coverts, conspicuous whitish tips of greater coverts (wingbar), whitish fringes of tertials; tail dusky, feather tips white; chin to breast and flanks pale ashy grey, rest of underparts cinnamon-rufous, undertail dark grey with white tips; iris yellowish; bill dark grey; legs dark grey. Female is greyish-buff overall, buff-brown back broadly striped blackish, whitish underparts heavily striped blackish-brown, blackish-brown wings with two narrow white wingbars. Juvenile undescribed. VOICE. Call "errrrrrr", repeated several times, with notes shortening and falling in pitch, similar to call of *P. rutila* but more squeaky, less mechanical-sounding.
Habitat. Sparse desert scrub and mostly barren coastal dunes, with large bushes openly dispersed, from sea-level to 550 m. Preferred habitat sparse dry mist forest contains algarrobo (*Prosopis pallida*), *Acacia macrocantha* and *Cucurbita*, with dense and diverse layer of flowering shrubs including *Capparis scabrida*, *C. angulata*, *C. ovalifolia*, *Cercidium praecox*, *Cordia lutea*, *Galvezia limensis*, *G. fructicosa*, *Maytenus octogona* and *Psittacanthus chanduyensis* (some of which are very scarce and localized). Also occurs in riparian thickets and low dense or open woodlands, usually dominated by *Prosopis* trees, with some *Acacia*.
Food and Feeding. Herbivore; feeds on buds, shoots and leaves of *Prosopis* and other trees and shrubs, also some fruit. Forages in pairs or small groups.
Breeding. Specimens of two males with active gonads and of laying female in Mar, male with slightly enlarged testes in Apr, and three specimens with inactive gonads in Apr, Aug and Sept; in Aug, male atop a bush and holding twig in its bill seen to fly over to a female. Clutch probably 2-4 eggs; incubation and fledging periods not recorded.
Movements. Resident.
Status and Conservation. ENDANGERED. Restricted-range species: present in Tumbesian Region EBA. Range very small and severely fragmented, with records from only eight locations since late 1990s, and much apparently suitable habitat unoccupied. Formerly, small populations known from 14 localities covering most of coastal NW Peru, from Tumbes S to Lima. Currently, c. 80% of global population found in Talara region of Piura (from Quebrada Salada to Quebrada Ancha and S to Cerro Negro), where estimated 50,000 ha of habitat holding 500-1000 individuals; elsewhere, survives in small forest fragments around Chiclayo area of Lambayeque, including Reque, Rafan, Murales forest, Batan Grande, Chaparri Private Protection Area and Siete Techos, each of which only a few hundred hectares in size and each holding c. 20-40 individuals. More recent records extend as far N as Máncora (N Piura) and as far S as Virú, S of Trujillo (La Libertad). Most of remaining habitat in Talara area owned, and hitherto protected, by the national petrol company (PetroPerú), which is currently collaborating with Peruvian conservationists and the National Audubon Society with aim of establishing a 10,000-ha reserve; programme designed to raise public awareness in the region also initiated. In rest of species' range, all forests threatened by burning, grazing, cutting for timber, firewood and charcoal, and conversion to cultivation (especially sugar cane), the factors that presumably destroyed the historical sites; considerable proportion of habitat close to Rafan is degraded, and parts of this area were converted to sugar production in 1990s. Murales forest is protected as an Archeological Reserved Zone and strict wardening has maintained habitat, but land rights to part of Murales were sold for agricultural conversion in 1999, and government intervention was necessary to prevent further sales of land for agriculture. Until re-

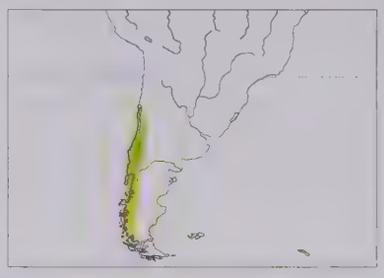
cently, this species was classed as Critical; in view of the numerous and immediate threats facing it, it should probably be returned to that category.
Bibliography. Anon. (2001a), Best & Kessler (1995), Bond (1956a), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cracraft (1985), Flanagan & Malo (2000), Flanagan & More (2003), Hellmayr (1929), Koepcke (1961, 1970), Meyer de Schauensee (1982), Parker *et al.* (1996), Plenge (1979), Ridgely & Tudor (1994), Schlatter (1985), Schönwetter & Meise (1969), Stattersfield & Capper (2000), Stotz *et al.* (1996), Taczanowski (1883), Traylor (1979a).

3. White-tipped Plantcutter

Phytotoma rutila

French: Rara du Paraguay **Spanish**: Cortarramas Argentino
German: Zweibinden-Pflanzenmäher
Other common names: Red-breasted/Reddish Plantcutter; Bolivian Plantcutter (*angustirostris*)

Taxonomy. *Phytotoma rutila* Vieillot, 1818, Paraguay.
Genus formerly treated as constituting a separate family of uncertain affinities or, sometimes, as a subfamily within Tyrannidae; more recent genetic data, however, indicate close relationship, possibly as sister-group, to a cotingid clade formed by the genera *Ampelion*, *Doliornis* and *Zaratornis*. Forms superspecies with *P. raimondii*. Two subspecies recognized.
Subspecies and Distribution.
P. r. angustirostris d'Orbigny & Lafresnaye, 1837 - highlands of C & S Bolivia (La Paz and Santa Cruz S to Tarija), and N Argentina (around Pichanal, in N Salta).
P. r. rutila Vieillot, 1818 - W Paraguay (E to near R Paraguay), N & E Argentina (S to Mendoza, La Pampa, Río Negro and CE Chubut) and W Uruguay.



Descriptive notes. 18-19·5 cm; 30-57 g. Distinctive, with short crest, conspicuous pale iris, short, stout, conical bill with finely serrated edges. Male has rufous forehead, dark grey crown and upperparts with sparse slaty streaks, dusky blackish wings and tail, two broad white wingbars (lower one sometimes lost through wear), conspicuous white tips of tail feathers (except central pair); chin and throat to ventral region rufous, except for grey-brown sides and flanks; whitish underwing-coverts, dark grey undertail with white tips; iris pale yellowish to hazel; bill dark grey to blackish; legs dark grey. Female has head and upperparts blackish-brown, white streaks on head, buffish-grey streaks on back, wings blackish-brown with 1-2 (depending on state of wear) narrow white wingbars, pale edges of tertials, outer web of outer tail feather edged white, underparts buffy to ochraceous with conspicuous blackish-brown streaks. Juvenile is grey-brown above, feathers faintly tipped brownish, upper wingbar broader, tail like female's, underparts uniformly buff-brown; immature male is obscurely streaked blackish-brown above, buffy grey-brown below, belly whitish, flanks rufous-buff, sometimes faint blackish-brown streaks on breast and upper belly; immature female resembles adult, but has vent more ochraceous. Race *angustirostris* differs from nominate in having stronger bill and broader white tail tip. VOICE. Usual call, by both sexes, a mechanical "errrrrrr", like sound made by winding old-fashioned alarm clock, sometimes repeated several times, and sometimes followed by lower and shorter "errrr"; also scratchy sounds during foraging.
Habitat. Chaco woodland, open woodland and woodland edge with dense undergrowth, also riparian thickets, *pampas*, arid lowland and montane scrub, semi-open groves with acacia (*Acacia*) and other thorny bushes (e.g. *Prosopis* and *Berberis* in Andes); also gardens, orchards, agricultural land in semi-arid regions. Sea-level to 1800 m in most of range; 600-3600 m in Andes.
Food and Feeding. Herbivore; feeds mainly on foliage (up to 90% of diet); some fruits and flowers also taken. Food items include buds, shoots and leaves of various species (e.g. *Lycium*, *Prosopis*, *Celtis tala*, *Schinus longifolius*, *Acacia*), and *Prosopis* seeds. Forages in pairs, family parties, small groups, or even flocks of up to 100 individuals; usually 3-4 m up in tree and shrub foliage, but sometimes on ground.
Breeding. Eggs in Jan-Feb and Sept-Dec; fledglings recorded in Dec and Jan, and juveniles in Dec, Feb, Mar and May; may raise two broods per year. Simple basket-shaped nest, diameter 10-17 cm, height 4·5-10 cm, made from small branches and lined with soft material, e.g. root fibres and sometimes grasses, often placed close to ground in thorny bush, also 1-4 m above ground in small tree or shrub. Clutch 2-4 eggs; incubation by female, period 14-15 days; chicks cared for by both parents, nestling period 17 days.
Movements. Resident and partial migrant. Some S populations move N after breeding, and those breeding at high elevations descend to lower levels in austral autumn; all records from Uruguay possibly involve migrants. One record from Brazil (Rio Grande do Sul).
Status and Conservation. Not globally threatened. Fairly common, even locally abundant seasonally. Not restricted to undisturbed habitats, as it occurs in agricultural lands and gardens. Nominate race occurs in several dozen protected areas in Argentina, Bolivia and Paraguay. N race *angustirostris* has declined as a result of widespread fragmentation and degradation of the natural bushy vegetation (e.g. *Prosopis* and *Berberis*) in Bolivian highlands, and is known to be present in only one protected area (Palmacito).

4. Rufous-tailed Plantcutter

Phytotoma rara

French: Rara à queue rousse **Spanish**: Cortarramas Chileno
German: Rotschwanz-Pflanzenmäher
Other common names: Chilean Plantcutter

Taxonomy. *Phytotoma rara* Molina, 1782, Chile.
Genus formerly treated as constituting a separate family of uncertain affinities or, sometimes, as a subfamily within Tyrannidae; more recent genetic data, however, indicate close relationship, possibly as sister-group, to a cotingid clade formed by the genera *Ampelion*, *Doliornis* and *Zaratornis*. Monotypic.
Distribution. C & S Chile (S fromVallenar, in S Atacama) and SW Argentina (S from Neuquen) S to Tierra del Fuego.

Descriptive notes. 18-20 cm; 38-44 g. Distinctive, with short crest, bright eye, short, stout, conical bill with finely serrated edges. Male has chestnut crown, blackish head side; hindneck and upperparts grey-brown, broadly streaked blackish-brown, wings blackish, broad white band on median wing-coverts and narrower one on greater coverts, tertials edged with buff; uppertail black, rufous inner webs; orange-rufous below, palest on belly, blackish underwing-coverts; dusky undertail with minute rufous-grey tips and broad rufous subterminal band on outer rectrices; iris reddish, rarely orange; bill blackish; legs dark grey. Female has head side and upperparts light grey-brown, broadly streaked blackish-brown, two narrow buffy wingbars and buff edges of tertials, buffy underparts with dark brown streaks, belly plainer. Juvenile is uniformly grey-brown with narrow buffy wingbars; immature male differs from adult in having black-brown streaks on crown, underparts streaked blackish-brown and buffy admixed with rufous. VOICE. Mechanical-sounding rasp, "e-e-e-e-e-e-e-e-e-e-errrrrrrr", initial notes accelerating and rising in volume and slightly in pitch, final "errrrrrrr" like sound made by the winding of an old-fashioned alarm clock. Contact call a mechanical "rara-rara".
Habitat. Open thorny scrub (e.g. with *Berberis* bushes), woodland edges, clearings in *Nothofagus* forest, and secondary forest; also farmland, hedgerows, orchards, vineyards, gardens. Sea-level to 2700 m.
Food and Feeding. Diet mainly grasses, buds, shoots and leaves, especially of legumes, also some fruits and berries; insects also taken. Clear preference for vegetative matter, especially young leaves of monocotyledons, e.g. wheat (*Triticum*) and oat (*Avena*). Berries taken include those of e.g. *Rubus ulmifolius*, *Aristotelia chilensis*, *Cestrum parqui* and *Myoporum tenuifolium*. Nestlings fed almost exclusively with insects. Forages in pairs in breeding season, in groups of 6-12 individuals at other times. Feeds both on ground and in foliage.
Breeding. Two seasons, in Oct-Nov and in Dec-Jan; eggs in Jan and Oct-Dec, nestlings in Nov. Shallow cup-shaped nest, diameter 14-18 cm, height 7-9 cm, loosely built from thin dry twigs and padded with root fibres, often placed 1-3 m above ground inside thick thorny shrub, also sometimes high in tree, usually in fork of horizontal branch. Clutch 2-4 eggs, old reports of 5-6 eggs considered unreliable; incubation lasts c. 2 weeks; nestling period not documented.
Movements. Resident in most of range. Those in far S migrate N after breeding; also, individuals breeding at higher altitudes wander to lower levels in austral winter. Accidental in Falkland Is.
Status and Conservation. Not globally threatened. Fairly common and widespread. Not restricted to undisturbed habitats, as it occurs in secondary forest, agricultural areas and even gardens. Occurs in many protected areas, e.g. La Campana Peñuelas Biosphere Reserve and Puyehué National Park, in Chile, and Nahuel Huapi and Los Glaciares National Parks, in Argentina. Considered an agricultural pest in some parts of range, owing to its habit of eating young leaves of commercial cereal crops; sometimes causes local damage in gardens and fruit orchards.

Genus *AMPELION* Tschudi, 1845

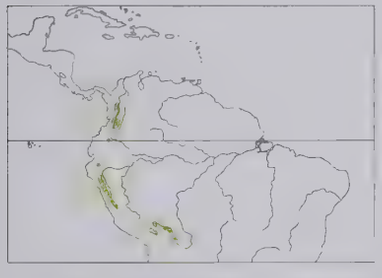
5. Red-crested Cotinga

Ampelion rubrocristatus

French: Cotinga à huppe rouge **German**: Rotschopfkotinga **Spanish**: Cotinga Crestirrojo

Taxonomy. *A[mpelis] rubro-cristata* d'Orbigny and Lafresnaye, 1837, Ayopayo, Cochabamba, Bolivia.
Genus appears to form a clade with *Doliornis* and *Zaratornis*; anatomical research and recent genetic data indicate close relationship to *Phytotoma*. Monotypic.
Distribution. N Colombia (Santa Marta Mts), also Sierra de Perijá (Colombia-W Venezuela border); and Andes from W Venezuela (S from NE Trujillo) and Colombia S to Bolivia (S to Santa Cruz).

Descriptive notes. 21-21·5 cm; male 51-80 g, female 47-67 g. Plain cotinga with long crest, which usually laid flat along nape, but may be conspicuously displayed, raised and spread transversely. Plumage is grey, darker on head and, especially, on wings and tail; nuchal crest chestnut-maroon; white streaking on tail-coverts both above and below, extending to variable degree across rump and vent; white subterminal bar on tail (visible from below or in flight); iris deep red; base of bill ivory-white or very pale grey, tip blackish-grey; legs black or dark grey. Sexes alike in plumage. Immature paler than adult, with extensive pale



feather fringes, diffuse rufous coloration mostly on head and neck; passes through succession of stages before gaining adult plumage. Voice. Commonest call a guttural, frog-like note, "rrrreh"; also, when disturbed, series of soft, nasal "eh-eh-eh...".
Habitat. Edges of cloudforest, patches of trees and bushes, locally hedgerows with trees bordering agricultural land. Mainly 2500-3900 m, exceptionally down to 2200 m.
Food and Feeding. Mainly fruits; occasionally insects. In E Andes of Colombia, fruits of 8 species (from 8 families) recorded, with *Schefflera bogotensis* (Araliaceae) and *Hieronyma huilensis* (Euphorbiaceae) numerically the most important. Fruits usually plucked during aerial sally, sometimes from perched position; flying insects taken in short sallies from exposed perches. Sometimes in small groups of up to six individuals.
Breeding. Laying recorded in Jan in Peru and Nov in Bolivia; records of moult, presumably post-breeding, suggest no clearly defined breeding season in any part of range. Raises and spreads crest, lifts tail and bows during courtship. Nest a large cup of mosses, lichens and twigs, sited 1·3-3 m above ground in bush or on low tree branch. Clutch size not recorded, but one nest contained single nestling, and brood of two recently fledged young observed; incubation and fledging periods not documented.
Movements. Presumably resident.
Status and Conservation. Not globally threatened. Common to fairly common. Very wide range and tolerance of variety of disturbed habitats should ensure its survival. Occurs in several protected areas throughout range, including Sierra Nevada National Park (Venezuela), Munchique National Park (Colombia) and Podocarpus National Park (Ecuador).
Bibliography. Arango (1990), Baez *et al.* (1997), Best & Clarke (1991), Best *et al.* (1997), Bloch *et al.* (1991), Butler (1979), Chapman (1921), Fjeldså & Krabbe (1990), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Koenen & Koenen (2000), Koepcke (1961, 1970), Meyer de Schauensee (1982), Ortiz & Carrión (1991), Parker *et al.* (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Vuilleumier (1969), Walker (2001), Williams & Tobias (1994).

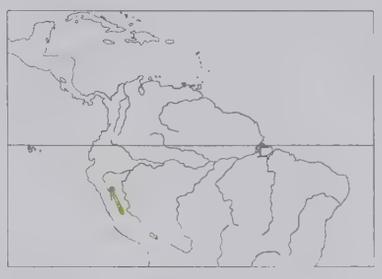
6. **Chestnut-crested Cotinga**

Ampelion rufaxilla

French: Cotinga à tête rousse **German**: Braunohrkotinga **Spanish**: Cotinga Cresticastaño

Taxonomy. *A[mpelis] rufaxilla* Tschudi, 1844, Vitoc Valley, Junín, Peru.
Genus appears to form a clade with *Doliornis* and *Zaratornis*; anatomical research and recent genetic data indicate close relationship to *Phytotoma*. Two subspecies recognized.
Subspecies and Distribution.
A. r. antioquiae (Chapman, 1924) - Andes of Colombia (W range in Valle and Cauca, and C range S to Huila) and probably extreme N Ecuador (W Sucumbíos).
A. r. rufaxilla (Tschudi, 1844) - Andes of extreme S Ecuador (S Zamora-Chinchipe), Peru, and Bolivia (La Paz, Cochabamba).

Descriptive notes. c. 21 cm; male 71-77 g, female 69-74 g. Long nuchal crest usually at least partly visible, sometimes conspicuously displayed. Nominate race has grey on face, becoming blackish on lores and forecrown; much of rear crown, including elongated feathers, bright chestnut; lower head to throat largely cinnamon; upperparts olive-grey with dusky streaks; wings and tail blackish, bright chestnut on shoulder; chest olive-grey, rest of underparts pale yellow, boldly streaked blackish; iris bright red; bill black, blue-grey base; legs dark grey or dark olive. Sexes alike in plumage. Immature unrecorded. Race *antioquiae* is somewhat larger than nominate, with wider and more numerous streaks below, chestnut areas darker. Voice. Long, guttural "ch-ch-ch-rrrrrreh", longer than that of *A. rubrocristatus*; also short "reh" notes.
Habitat. Montane forest; 1750-2740 m.
Food and Feeding. Fruits and insects, the latter regularly taken in flight sallies.
Breeding. Little known. Laying recorded in Dec in SE Peru, and female with enlarged ovary collected in Apr in S Colombia. Only one nest recorded, in SE Peru, an open, unlined cup made almost wholly of lichens, slender twigs woven into base, c. 12 m up in crown of evergreen tree. No further information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Uncommon to rare, and often rather local, throughout most of range. Very rare and local, and extremely few records, in Ecuador, where first recorded in 1984 in N and in 1987 in S; apparent absence from almost entire country difficult to explain. Occurs at lower elevations than *A. rubrocristatus*, and lacks that species' wide habitat tolerance.
Bibliography. Best *et al.* (1997), Chapman (1917c), Fjeldså & Krabbe (1990), Hellmayr (1929), Hilty (1985), Hilty & Brown (1986), Meyer de Schauensee (1982), Parker *et al.* (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg & Servat (2001), Schulenberg *et al.* (2001), Stotz *et al.* (1996), Walker (2001).



Genus *DOLIORNIS* Taczanowski, 1874

7. **Bay-vented Cotinga**

Doliornis sclateri

French: Cotinga de Sclater **German**: Braunbauchkotinga **Spanish**: Cotinga de Sclater

Taxonomy. *Doliornis sclateri* Taczanowski, 1874, Maraynioc, central Peru.
Genus sometimes merged with *Ampelion*, but differs in bill structure and juvenile plumage. Both genera, along with *Zaratornis*, appear to form a clade, which suggested by anatomical research and recent genetic data as being closely related to *Phytotoma*. Monotypic.
Distribution. E slopes of Andes in C Peru.
Descriptive notes. 21·5 cm; male 54-69 g, female 53-67 g. Male has black lores, forehead and crown, maroon-chestnut nuchal crest (usually concealed or semi-concealed); grey face, throat and

mantle, becoming dark greyish on rest of upperparts, browner on wings and tail; underparts brown, undertail-coverts brighter, reddish-brown; iris grey; upper mandible black, lower mandible blue-grey with black tip; legs dark grey. Distinguished from similar *D. remseni* by paler head, duller lower underparts. Female differs from male in having forehead and crown grey, only lores black. Juvenile has breast and belly clay-coloured with indistinct olive-brown streaks; immature unrecorded. Voice. Rasping "shhh", varying in length and intensity.
Habitat. Temperate-zone cloudforest, at or near tree-line; 2500-3600 m.
Food and Feeding. Mainly fruits; also insects.
Breeding. Occupied nest seen in Apr or May, c. 4 m above ground on fork of slender tree branch. No further details.
Movements. Resident; extremely sedentary, individuals often remain in same small patch of trees for weeks.
Status and Conservation. Not globally threatened. Restricted-range species: present in Northeast Peruvian Cordilleras EBA. Known range small, and apparently present in low numbers where found. These factors, combined with threat of habitat destruction, suggest need for monitoring.
Bibliography. Clements & Shany (2001), Cracraft (1985), Fjeldså & Krabbe (1990), Hellmayr (1929), Meyer de Schauensee (1982), Parker *et al.* (1982), Rasmussen *et al.* (1996), Ridgely & Tudor (1994), Robbins *et al.* (1994), Stotz *et al.* (1996), Zimmer (1936a).

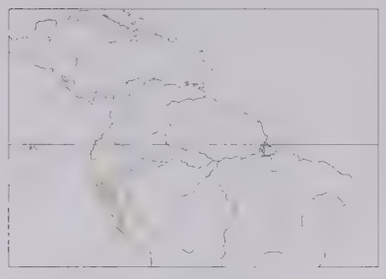
8. **Chestnut-bellied Cotinga**

Doliornis remseni

French: Cotinga de Remsen **German**: Kastanienbauchkotinga **Spanish**: Cotinga de Remsen

Taxonomy. *Doliornis remseni* Robbins *et al.*, 1994, Cerro Mongus, Carchi, Ecuador.
Genus sometimes merged with *Ampelion*, but differs in bill structure and juvenile plumage. Both genera, along with *Zaratornis*, appear to form a clade, which suggested by anatomical research and recent genetic data as being closely related to *Phytotoma*. Monotypic.
Distribution. C Andes of Colombia (Quindío) and locally in E Andes of Ecuador.

Descriptive notes. 21·5 cm; male 58·5-72 g, one female 64 g. Male has black top of head, dark orange-red nuchal crest (usually concealed or mostly so); rest of head dark grey, upperparts darker, blackish; breast dark greyish, rest of underparts rich rufous-chestnut; iris dark red-brown; bill slate-grey to black; legs dark grey to black. Distinguished from similar *D. sclateri* by darker head, rich rufous-chestnut lower underparts. Female differs from male in having extensive grey feather fringes on head. Immature is like adult. Voice. Not recorded.
Habitat. Stunted woodland at or near tree-line; 2900-3650 m, mostly above 3100 m.
Food and Feeding. Only recorded food items are fruit, including those of *Escallonia* and *Miconia chlorocarpa*.
Breeding. No information.
Movements. None recorded.
Status and Conservation. VULNERABLE. Restricted-range species: present in Central Andean Páramo EBA. First discovered in 1989; currently known from only six localities, one in Colombia and remaining five in Ecuador. Rare and extremely local, and total population probably small; in Colombia, 0·3 individuals/10 km in transect counts. Species' preferred habitat highly fragmented, as large areas of suitably dense thickets already destroyed. Habitat loss and degradation continuing, mainly through uncontrolled burning; grazing, firewood-gathering and cultivation are further threats. Occurs in Cañón del Quindío National Park, in Colombia, and Podocarpus National Park and Guandera Biological Reserve, in Ecuador, but other sites have no protection at all. Extensive further field investigation required in order to gain more accurate information on this species' precise distribution and status. Reported as occurring in extreme N Peru, in Cordillera Las Lagunillas, but that range is in extreme S Ecuador.
Bibliography. Anon. (1995a), Best *et al.* (1997), Bloch *et al.* (1991), Collar *et al.* (1994), Cresswell *et al.* (1999), Granizo *et al.* (1997), Guerrero (2002b), Rasmussen *et al.* (1996), Renjifo (1994), Ridgely & Greenfield (2001), Robbins *et al.* (1994), Stattersfield & Capper (2000), Stotz *et al.* (1996), Wege & Long (1995).



Genus *ZARATORNIS* Koepcke, 1954

9. **White-cheeked Cotinga**

Zaratornis stresemanni

French: Cotinga à joues blanches **German**: Weißohrkotinga **Spanish**: Cotinga Cariblanco

Taxonomy. *Zaratornis stresemanni* Koepcke, 1954, River Rímac, Lima, Peru.
Genus sometimes merged with *Ampelion*, but differs in details of skull structure and has distinct plumage. Both genera, along with *Doliornis*, appear to form a clade, which suggested by anatomical research and recent genetic data as being closely related to *Phytotoma*. Monotypic.
Distribution. Andes of W Peru (La Libertad S locally to Ayacucho).
Descriptive notes. 21 cm; male 46-57 g, female 47-55 g. Has black cap, white face, grey at rear auriculars; upperparts dark brown with brownish-buff streaks; median and lesser wing-coverts as back, greater coverts and remiges dusky with very narrow pale edges; tail mostly dusky; neck and

chin to upper breast brownish-grey; rest of underparts cinnamon-buff with bold blackish streaks, less marked in centre; iris red; bill lead-blue, paler towards tip; legs dark brown to blackish. Sexes alike. Immature undescribed. VOICE. Main call a loud, low-pitched series of notes, nasal in quality, "reh-reh-reh-reh-rrrrrrrrrr-re-re", speeding up to a roll towards middle, ending with 2-3 emphatic notes, lasting on average 4 seconds; drawn-out "raaa-aaah" when disturbed or alarmed.

Habitat. High-altitude woodland, mainly of *Polylepis-Gynoxys*, at 3250-4250 m; presumed non-breeders also recorded in mixed woodland down to 2000 m in dry season.

Food and Feeding. Primarily fruits of mistletoes (of genera *Tristerix*, *Ligaria*); an individual recently observed to eat the buds of a shrub subsequently identified as *Berberis lutea*. Seems almost wholly dependent on mistletoes, as few or no other fruit-producing plants occur in its main habitat. Plucks food items while perched.

Breeding. Laying in Apr-May. Nest a deep cup of mosses and lichens, with a few small twigs, lined with coarse grasses, well hidden within large clump of mistletoe (*Tristerix*) 4-7 m above ground on *Polylepis* tree. Clutch 3 eggs; incubation and fledging periods not recorded.

Movements. Probably resident in breeding habitat (*Polylepis* woodland), with some post-breeding dispersal to lower levels; in Aug-Nov dry season, presumed non-breeders recorded in mixed woodland at 2500-2900, irregularly down to 2000 m.

Status and Conservation. VULNERABLE. Restricted-range species: present in Peruvian High Andes EBA. Locally common but patchily distributed. Global population small, estimated at 1500-6000 individuals in 1992; largest known population at Pueblo Quichas, c. 500 individuals in 1987. *Polylepis* woodland, on which it is dependent, is patchily distributed and locally subject to felling, as well as cutting for firewood and charcoal; also, woodland regeneration often prevented by heavy grazing pressure and uncontrolled fires. Occurs in Huascarán National Park in N (Ancash) and Pampa Galeras National Reserve in S (Ayacucho), but protection of habitat inadequate in both. This species is probably the main dispersal agent for *Tristerix* and *Ligaria* mistletoes within its range.

Bibliography. Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fjeldså & Krabbe (1990), Koepcke (1954, 1955, 1970), Maynard & Waterton (1998), Meyer de Schauensee (1982), Parker (1981), Plenge (1979), Pulido (1991), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stotz *et al.* (1996).

Genus *LANIISOMA* Swainson, 1832

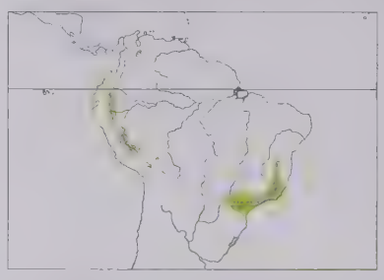
10. **Elegant Mourner**

Laniisoma elegans

French: Cotinga élégant **German**: Schwarzkappenkotinga **Spanish**: Cotinga Elegante
Other common names: Shrike/Shrike-like Cotinga; Buckley's Mourner, Andean Laniisoma (Andean races)

Taxonomy. *Ampelis elegans* Thunberg, 1823, mountains of Rio de Janeiro, Brazil.

Phylogenetic affinities uncertain. Traditionally included within present family, but recent analysis of morphology indicated possible relationship with genera currently placed in Pipridae (*Schiffornis*) and Tyrannidae (*Laniocera*, *Xenopsaris*, *Pachyramphus*), possibly also with cotingid genus *Iodopleura*; further research required. Andean races (*venezuelense*, *buckleyi*, *cadwaladeri*) often treated as a separate species, but no apparent vocal differences from nominate and plumage differences considered minor. Four subspecies recognized.



Subspecies and Distribution.

L. e. venezuelense Phelps, Sr & Gilliard, 1941 - foothills of E Andes in W Venezuela (Táchira, Barinas) and Colombia (Boyacá).

L. e. buckleyi (P. L. Sclater & Salvin, 1880) - foothills of Andes in Ecuador and Peru.

L. e. cadwaladeri Carriker, 1935 - foothills of Andes in NW Bolivia (La Paz).

L. e. elegans (Thunberg, 1823) - SE Brazil (S Bahia S to São Paulo and E Paraná).

Descriptive notes. 17·5-18 cm; male 41-46 g, two females 45·8 g and 51 g (*buckleyi*). Distinctive, with rather long bill with straight culmen ridge, abruptly hooked at tip, rictal bristles well developed; tarsus slender, outer toe partly united with middle toe. Male nominate race has black cap, olive-green upperparts, wing and tail; primary P7 attenuated distally and slightly recurved, projecting beyond P6 and P8; yellow below, some black spots on throat, becoming bars downwards; iris dark brown; upper mandible blackish, lower yellowish-horn; legs brownish to greyish-olive. Female is similar to male, but cap not solidly black, underparts more extensively barred, primaries not modified. Immature resembles female, but wing-coverts broadly tipped cinnamon. Races vary only slightly: *buckleyi* male is smaller than nominate, brighter, less extensively barred below, female has crown more or less concolorous with back, well-barred underparts; *cadwaladeri* resembles previous, male possibly even less barred below; *venezuelense* differs from last in slightly brighter upperparts, less heavily barred flanks. VOICE. Territorial call of male a very thin, high-pitched "psiiiiiiieeeee", regularly repeated.

Habitat. Humid forest and mature secondary woodland; often near streams in Andean foothills. Mainly 400-1800 m, but down to 200 m in Venezuela; in SE Brazil mostly to c. 900 m, and locally below 100 m in extreme S (Ilha do Cardoso).

Food and Feeding. Fruit and insects; few details, but berries of Melastomataceae recorded. Regularly clings to vertical perches, sometimes descending close to ground, but degree to which this associated with foraging uncertain. Occasionally joins mixed-species flocks; also observed together with *Phibalura flavirostris* in SE Brazil.

Breeding. No definite information available. Gonad data suggest breeding probably occurs in austral spring-summer in SE Brazil, but individuals also recorded in moult during this period. Two undated nestlings, collected in E Ecuador during 19th century, have long, filamentous white-tipped down feathers, suggesting cryptic adaptation (perhaps resembling fruiting moss) to an exposed nest.

Movements. In SE Brazil (nominate race), moves from interior forests to lowlands in austral winter; presumed passage migrants recorded São Paulo city in May (hitting house) and Oct (in city park). Apparently resident in Andes.

Status and Conservation. Not globally threatened. Nominate race classed as Vulnerable. Generally rare and local in both W & E parts of range; although easily overlooked and probably underrecorded, it seems to occur in very low densities in the relatively few places where known to be present. Rare in SE Brazil (nominate race), where increasingly substantial deforestation and habitat fragmentation have led to decline in numbers, and only few recent records; occurs in more than ten reserves, including three national parks (Itatiaia, Tijuca, Serra da Bocaína), but effective protection of these is rarely guaranteed. In Andes, rare in N part of range (*venezuelense*), with only six specimens from Venezuela (where no recent records) and one record from Colombia; thought to be almost certainly more widespread than is currently known. Farther S, race *buckleyi* is rare to very rare in Ecuador (classified as "Near-threatened" in that country), with records from no more than c. 12 localities, including single report from Podocarpus National Park; rare in Peru. Bolivian *cadwaladeri* very poorly known, with only two definite observations; one seen in Pilón Lajas Biosphere Reserve in Sept 1999. Andean races, if treated as a separate species, probably merit the conservation status of Vulnerable.

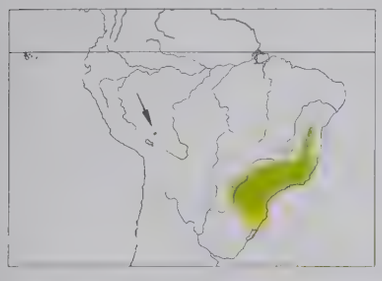
Bibliography. Anciães *et al.* (2001), Carriker (1933), Collar & Andrew (1988), Collar *et al.* (1992), Cracraft (1985), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Hinojosa *et al.* (1998), Lo (1994), Mallet-Rodrigues & Marinho (2003), Prum & Lanyon (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ruschi (1979), Sick (1993, 1997), Snow (1975b), Stattersfield & Capper (2000), Stotz *et al.* (1996), Thoresen (1974), Williams (2002b)

PLATE 2 ➤

PLATE 2

inches 4

cm 10



Genus *PHIBALURA* Vieillot, 1816

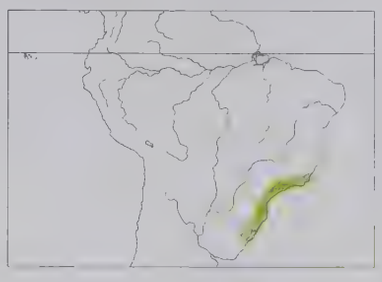
11. Swallow-tailed Cotinga

Phibalura flavirostris

French: Cotinga à queue fourchue **German**: Gabelschwanzkotinga **Spanish**: Cotinga Tijereta

Taxonomy. *Phibalura flavirostris* Vieillot, 1816, Rio de Janeiro, Brazil.
Geographically isolated race *boliviana* rather distinctive, may represent a separate species. Two subspecies recognized.
Subspecies and Distribution.
P. f. flavirostris Vieillot, 1816 - SE Brazil (from C Bahia, S Goiás, Minas Gerais and Espírito Santo S to Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).
P. f. boliviana Chapman, 1930 - foothills of Andes in W Bolivia (vicinity of Apolo, in La Paz).

Descriptive notes. 21·5-22 cm; one male 43·5 g, two females 44 g and 52 g. Highly distinctive cotingid with long and forked tail, outer rectrices progressively longer and more pointed, rather long and pointed wing, very short, broad-based bill, bristly feathers around base of upper mandible and a few at base of lower mandible; legs and feet slender. Male nominate race has top of head black, with grey on side of crown, some dark red on rear crown, black ear-coverts; upperparts spotted olive and black (looking barred), wings and tail mostly bluish-black; throat yellow (feathers with short shafts and long barbs, brush-like); neck and chest white with black bars and spots; rest of underparts white with ochraceous scaling, some black markings; iris dark chestnut-brown, orbital ring pink or reddish; bill pale straw-coloured to pale fleshy yellow; legs dull pink. Female is similar to male but duller, more olive on wings, more extensive black markings (bar-like) below. Immature is like adult, but black areas duller and browner, barring on underparts heavier, throat feathers black-spotted, wing and tail feathers green-edged. Race *boliviana* differs from nominate in having wider, unmarked white postauricular area, longer tail, less yellow on throat, less barring below, feet more orange-toned, also less sexually dimorphic. Voice. Generally silent; two calls recorded for nominate race are a high guttural whistle and, without further detail, a "tremolo"; for *boliviana* a succession of harsh but rather weak notes, at c. 1-second intervals.
Habitat. Forest borders, partially wooded areas, and open areas and gardens with trees, from near sea-level to 2000 m; often nests in gardens in Brazil. Bolivian race (*boliviana*) inhabits open humid forest and forest fragments at 1400-2000 m.
Food and Feeding. Mainly fruits, also insects. Fruits especially of various mistletoe species (Loranthaceae), also of Myrsinaceae and Rubiaceae, recorded for nominate race; those of *Didymopanax morototoni* (Araliaceae) recorded for *boliviana*. Insects usually taken in flight, often by hawking; is the most aerial member of the family. Forages in loose groups of 15-20 individuals outside breeding season; sometimes associates with *Laniisoma elegans* in SE Brazil.
Breeding. Laying in Oct-Jan and adult with juvenile in Dec in Brazil; laying in Sept-Oct in Bolivia. Male possibly helps female to build nest, a small shallow cup made mainly or entirely of lichens, placed either in fork or on thick horizontal branch of tree, 2-18 m above ground in Brazil, 1·4-1·8 m above ground in Bolivia. Clutch 2-3 eggs; incubation by female, possibly assisted by male, which said also to feed her on nest, period not documented; both sexes feed nestlings, fledging period not recorded.
Movements. Brazilian population partially migratory, present in extreme S (Rio Grande do Sul) only between late Sept and late Mar, moving N after breeding; farther N, in main part of range, makes post-breeding movement from mountains down to lower levels. Resident in Bolivia.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Generally rare, locally uncommon, nowhere very common. Nominate race is locally uncommon in Itatiaia National Park (Minas Gerais-Rio de Janeiro border) and in Intervales State Park (São Paulo), also in Caraça area of Minas Gerais, but apparently rare elsewhere, even in protected areas (e.g. Serra dos Órgãos National Park); records in S Goiás and in Chapada Diamantina National Park (Bahia) possibly involve non-breeding migrants from S; very rare in Argentina (Misiones) and no recent records from Paraguay. This race is believed to have declined, but reasons not clear; although extensive deforestation has occurred within its range, it is not dependent on primary forest and is able to use man-made habitats; indeed, it seems to prefer forest borders and lightly wooded areas, and often nests in gardens with scattered trees (a habit unique among cotingids), which should ensure future survival of, at least, Brazilian population. Reported, surprisingly, as sometimes hunted for food in Brazil. Bolivian race (*boliviana*), rediscovered as recently as 2000, 98 years after original discovery, is apparently confined to a restricted area (possibly of less than 50,000 ha) of open forest and humid forest fragments around city of Apolo; receives some protection, as part of area is within Madidi National Park. If recognized as a distinct species, it should be considered globally threatened.
Bibliography. Bromfield *et al.* (2004), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Collar & Andrew (1988), Cracraft (1985), Descourtilz (1983), Forrester (1993), Fraga & Narosky (1985), Goeldi (1894), Guix *et al.* (1992), Hayes (1995), Hellmayr (1929), Hennessey (2002), Krabbe (1984), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Parrini *et al.* (1999), de la Peña (1989), Ridgely & Tudor (1994), do Rosário (1996), Saibene *et al.* (1996), Sick (1993, 1997), Snow (1982), Stattersfield & Capper (2000), Stotz *et al.* (1996).



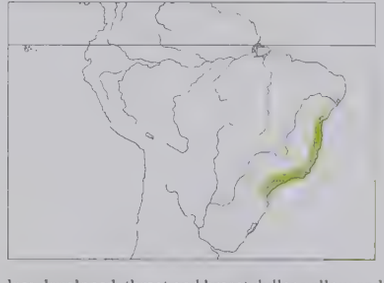
Genus *CARPORNIS* G. R. Gray, 1846

12. Hooded Berryeater

Carpornis cucullata

French: Cotinga coqueluchon **Spanish**: Cotinga Encapuchado
German: Braunmantel-Beerenfresser

Taxonomy. *Procnias cucullata* Swainson, 1821, Rio de Janeiro, Brazil.
Genus was in the past sometimes merged with *Ampelion*, but now considered distinct, and not even amongst closest relatives. Monotypic.
Distribution. SE Brazil, from Espírito Santo S to Rio Grande do Sul.



Descriptive notes. 22·5-23 cm; male 73·5-80 g, three females 67-84·4 g. Well-marked cotingid with rather long, square-cut tail. Male has black hood extending to hindneck and chest, narrow yellow hindcollar; back rather dark brown with chestnut tinge, rump and uppertail-coverts dull greenish-olive; wings and tail blackish with olive-green edgings, buffish-yellow tips of greater and median wing-coverts forming two wingbars; underparts from breast downwards yellow; iris dark brown, occasionally blue or fiery red; bill and legs mostly blue, grey-blue or violet-blue. Differs from *C. melanocephala* in upperpart colour, lack of barring below, also narrower and less dorso-ventrally compressed bill, relatively longer tail. Female is duller than male, head and body suffused or scaled with olive, more olive on wings and tail. Immature resembles female, but black on head even less developed, wing-coverts green (not blackish with green edges), throat and breast duller yellow and more barred. Voice. Male territorial call a stereotyped 4-syllable phrase, soft and mellow, "wo-op, wot-chuf"; both sexes make inward, grating notes.
Habitat. Humid lowland and montane forest, also palm groves; occurs at altitudinal range of 400-1600 m.
Food and Feeding. Mainly soft fruits; occasionally also large insects. Fruits on average of smaller size than those taken by *C. melanocephala*; in study at Intervales (São Paulo), fruits of 45 plant species (of 15 families) recorded in diet, average size 10·3 mm (range 4·2-22·3 mm). Usually solitary.
Breeding. No relevant information available. Data from moult, presumably post-breeding, suggest laying in Sept-Oct.
Movements. No information; probably sedentary.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Atlantic Forest Lowlands EBA. Poorly known species. Apparently rather uncommon throughout range, but this possibly due, at least in part, to its inconspicuous behaviour. In N of range, majority of suitable habitat in lowlands already destroyed, and species is now almost confined to montane forest. Occurs in several protected areas, including e.g. Serra dos Órgãos National Park, Augusto Ruschi Biological Reserve and Intervales and Serra do Mar State Parks. Main threats are continued agricultural expansion, human colonization and urbanization, and associated road-building.
Bibliography. Descourtilz (1983), Dinerstein *et al.* (1995), Forrester (1993), Gonzaga *et al.* (1995), Guix (1995), Guix *et al.* (1992), Hellmayr (1929), Mazar Barnett, Kirwan & Tobias (1998b), Meyer de Schauensee (1982), Parker *et al.* (1996), Pizo *et al.* (2002), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993), Venturini *et al.* (2001).

13. Black-headed Berryeater

Carpornis melanocephala

French: Cotinga à tête noire **German**: Olivmantel-Beerenfresser **Spanish**: Cotinga Cabecinegro

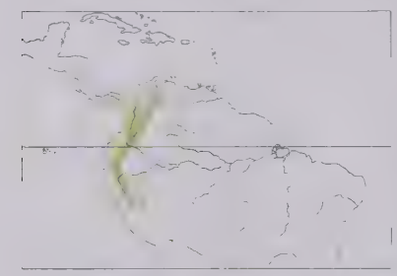
Taxonomy. *Procnias melanocephalus* Wied, 1820, Quartel das Barreiras, road from River Itapemirim to River Itabapoana, south Espírito Santo, Brazil.
Genus was in the past sometimes merged with *Ampelion*, but now considered distinct, and not even amongst closest relatives. Monotypic.
Distribution. E Brazil, locally in Alagoas (Murici) and from Bahia S along coast to NE Paraná.

Descriptive notes. 20·5-21 cm; two males 62·7 g and 66 g, 1 female 64 g. Male has black hood down to hindneck and lower throat, very thin yellow hindcollar; rather dull olive-green upperparts, wings and tail; underparts olive-yellow with weak and fine dark olive barring, plainer yellow on lower belly; iris fiery red or brick-red; bill blackish, plumbeous base of lower mandible; legs grey. Differs from *C. cucullata* in upperpart colour, barring below, also wider and more dorso-ventrally compressed bill, relatively shorter tail. Female is like male, some olive suffusion on head. Immature resembles female, but black on head less developed, throat and breast duller yellow and more barred. Voice. Male territorial call a loud, whistled "tuhweéo".
Habitat. Humid forest; occurs up to 500 m, and locally up to c. 700 m, but mostly found below 300 m. At one site in Espírito Santo (Linhares), found to favour dense vegetation, with many lianas and spiny palms, on dry sandy soil away from water; occurs also in tall *restinga* on Comprida I (São Paulo).
Food and Feeding. Predominantly fruits; a single record of a 7-cm stick-insect (Phasmida) being consumed. Fruits on average of larger size than those taken by *C. cucullata*; in observations at Intervales (São Paulo), fruits of 14 plant species (of 7 families), mainly those of Myrtaceae, recorded, with average width 14·8 mm (range 9·7-19·6 mm). The possibility that it plucks fruits while in flight more often than does *C. cucullata* is suggested by different bill shape and its lower wing-loading.
Breeding. No information. Vocal activity and gonad and moult condition of specimens indicate breeding probably in austral summer; moult data suggest more protracted season than that of *C. cucullata*.
Movements. No information.
Status and Conservation. VULNERABLE. Dependent on lowland forest, which has been extensively destroyed; total population probably low and clearly severely fragmented, and thought to have declined significantly. Currently confined almost exclusively to protected areas. Still locally fairly

On following page: 14. Green-and-black Fruiteater (*Pipreola riefferii*); 15. Band-tailed Fruiteater (*Pipreola intermedia*); 16. Barred Fruiteater (*Pipreola arcuata*).

common in a few places, particularly Murici Ecological Reserve (Alagoas), Linhares Natural Reserve (Espírito Santo) and Intervales State Park (São Paulo). Present also in two national parks (Monte Pascoal, Superagui), as well as three biological reserves and six other protected areas. Widespread clearance of forest remains a continuing problem in region, and harvesting of palmito palms (*Euterpe edulis*) may also be a threat; uncontrolled fires damage habitat, and forest at one site in Bahia was almost completely destroyed by fire in 1995. Official protection of forest at Murici a priority conservation target.

Bibliography. Aleixo & Galetti (1997), Anon. (1997c, 2002b), Collar & Andrew (1988), Collar *et al.* (1992), Cordeiro (2000), Cracraft (1985), Forrester (1993), Galetti & Aleixo (1998), Goerck (2001), Gonzaga *et al.* (1995), Guix (1995), Guix *et al.* (1992), Hellmayr (1929), Meyer de Schauensee (1982), Pizo *et al.* (2002), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Teixeira *et al.* (1988), Wege & Long (1995).



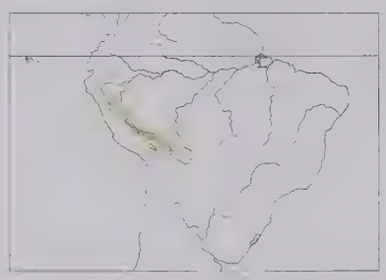
Genus *PIPREOLA* Swainson, 1838

14. Green-and-black Fruiteater

Pipreola riefferii

French: Cotinga vert et noir **German**: Goldbandkotinga **Spanish**: Frutero Verdinegro
Other common names: Black-headed/Huanuco/Tallmans' Fruiteater (*tallmanorum*)

Taxonomy. *Ampelis Riefferii* Boissonneau, 1840, "Bogotá", Colombia.
Closely related to *P. intermedia*, and has been treated as conspecific; in addition to differences in plumage (especially tail colour), however, the two overlap in range in C Peru and in some areas occur together, although they differ in altitudinal range. Distinctive race *tallmanorum*, from outlying mountains E of main Andean range, may merit species status. Race *confusa* possibly better merged with *chachapoyas*. Six subspecies recognized.
Subspecies and Distribution.
P. r. melanolaema P. L. Sclater, 1856 - mountains of NW & N Venezuela (S Lara S to C Táchira, and Aragua E to Miranda).
P. r. riefferii (Boissonneau, 1840) - Sierra de Perijá (on Colombia-Venezuela border), W Venezuela (W Táchira), and E & C Andes of Colombia.
P. r. occidentalis (Chapman, 1914) - W Andes (also extreme S end of C range) of Colombia and W slope in Ecuador.
P. r. confusa J. T. Zimmer, 1936 - E Andes of Ecuador and extreme N Peru (W Amazonas).
P. r. chachapoyas (Hellmayr, 1915) - N Peru E of R Marañón (in Amazonas and San Martín).
P. r. tallmanorum O'Neill & Parker, 1981 - Carpish Mts and Cerros de Sira, in Huánuco (Peru).



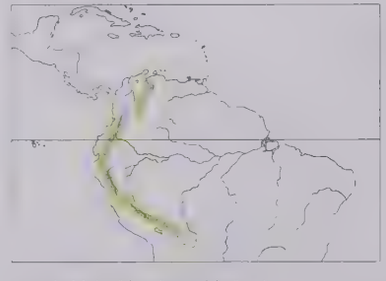
Descriptive notes. 17·5-20 cm; 46-61 g. Male nominate race has blackish-green hood down to chest, bordered by yellow collar (except on nape); green above, white tips of tertials; yellow below, with green streaks increasingly denser towards flanks; iris dark red-brown; bill bright red; legs red or orange-red. Distinguished from similar *P. intermedia* mainly by plainer tail, less patterned underparts. Female lacks hood and collar, has head and forebody to breast plain green. Juvenile is dark olive-green above, dull olive with yellow streaks below; adult plumage apparently acquired soon after fledging. Races differ mainly in size, and in shade of hood and amount of green markings on underparts of male: *melanolaema* has more contrasting wings, more solid yellow on central underparts, male hood glossy black (not greenish), female has ill-defined yellow collar; *occidentalis* male has throat and chest washed greenish, pale tertial tips less marked; *chachapoyas* is small, male hood black, underparts well marked with green streaks; *confusa* is like last, but male with more greenish upper breast and more strongly marked central underparts; *tallmanorum* is smallest, has brighter red eyes, male has glossiest black hood, unmarked yellow lower breast and belly, female lower underparts broadly streaked green. Voice. Very high-pitched, sibilant "ti-ti-ti-ti" for up to 5 seconds, dying away; call of *tallmanorum* distinct, "ti-ti-ti-seeee", last note very thin and high-pitched.
Habitat. Montane forest, forest borders and secondary woodland; mostly 1000-2900 m, locally higher, to 3050 m, exceptionally to 3300 m.
Food and Feeding. Apparently only fruit. In E Andes of Colombia, fruits of 16 plant species, from eight families, recorded, with those of Chloranthaceae, Ericaceae and Melastomataceae numerically most important. Plucks fruits while perched or during clumsy hover. Often accompanies mixed-species foraging flocks.
Breeding. Laying in Feb-Aug in W Colombia. Nest a substantial cup, almost entirely of moss, lined with black rootlets, placed 1-2 m above ground in bush or small tree. Clutch 2 eggs; no information on incubation and nestling periods.
Movements. None recorded.
Status and Conservation. Not globally threatened. Uncommon to fairly common or common. The most widespread and abundant of the Andean fruiteaters. Also, is ecologically the most tolerant. Occurs in several reserves and other protected areas.
Bibliography. Allen (1998), Arango (1990), Baez *et al.* (1997), Best *et al.* (1997), Bloch *et al.* (1991), Butler (1979), Chapman (1914), Chapman (1917c), Fjeldså & Krabbe (1990), Hilty (2003), Meyer de Schauensee (1982), Miller (1963), Moynihan (1979), O'Neill & Parker (1981), Parker (1997), Parker *et al.* (1985), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rutgers & Norris (1977), Schulenberg (2002), Schulenberg & Wust (1997), Stotz *et al.* (1996), Zimmer (1936a).

15. Band-tailed Fruiteater

Pipreola intermedia

French: Cotinga à queue rayée **German**: Schmuckbauchkotinga **Spanish**: Frutero Colifajado

Taxonomy. *Pipreola viridis intermedia* Taczanowski, 1884, Maraynioc, central Peru.
Closely related to *P. riefferii*, and has been treated as conspecific; in addition to differences in plumage (especially tail colour), however, the two overlap in range in C Peru and in some areas occur together, although they differ in altitudinal range. Two subspecies recognized.
Subspecies and Distribution.
P. i. intermedia Taczanowski, 1884 - E slope of Peruvian Andes, from La Libertad and San Martín S to Junín.
P. i. signata (Hellmayr, 1917) - E slope of Andes in SE Peru (Cuzco, Puno) and W Bolivia (La Paz, Cochabamba).



Descriptive notes. 19 cm; male 44-59 g, female 44-51 g. Male nominate race has blackish hood down to chest, obscure thin yellow collar (except on nape); green above, white tips of tertials, tail with black subterminal bar and white tip; yellow below, flanks green, with blackish markings giving scaled and spotted appearance; iris brown, sometimes grey; bill crimson, sometimes black culmen ridge; legs red or orange-red. Distinguished from similar *P. riefferii* mainly by tail pattern, more patterned underparts. Female lacks hood, has head and forebody to breast plain green, only faint hint of collar, also yellow eyering. Juvenile undescribed. Race *signata* male differs from nominate in having much more conspicuous yellow collar, central underparts bright yellow and almost unmarked. Voice. Very high-pitched trill, e.g. "tsi-tsi-tsi-tsiiii", 4-5 seconds long, similar to that of *P. riefferii*.
Habitat. Montane forest and forest borders; 2300-3100 m in Peru, 1100-2800 m in Bolivia.
Food and Feeding. Apparently only fruit.
Breeding. No information.
Movements. None recorded; individual recorded at lower elevation (1100 m) in Bolivia may indicate seasonal altitudinal movement.
Status and Conservation. Not globally threatened. Fairly common, but poorly known. Occurs in Madidi National Park, in Bolivia; in Peru, present in Machu Picchu Historical Sanctuary (Cuzco) and frequently observed at the Carpish Pass (Huánuco).
Bibliography. Clements & Shany (2001), Cracraft (1985), Fjeldså & Krabbe (1990), Hennessey, Herzog & Sagot (2003), Meyer de Schauensee (1982), Parker *et al.* (1982), Remsen & Traylor (1989), Ridgely & Tudor (1994), Stotz *et al.* (1996), Walker (2001), Zimmer (1936a).

16. Barred Fruiteater

Pipreola arcuata

French: Cotinga barré **German**: Bindenkotinga **Spanish**: Frutero Barrado

Taxonomy. *Ampelis arcuata* Lafresnaye, 1843, "Bogotá", Colombia.
Two subspecies recognized.
Subspecies and Distribution.
P. a. arcuata (Lafresnaye, 1843) - Sierra de Perijá (on Colombia-Venezuela border), and Andes of W Venezuela (E to SW Lara), Colombia, Ecuador and N & C Peru.
P. a. viridicauda Meyer de Schauensee, 1953 - Andes from C Peru (S from Junín) S to Bolivia (La Paz, Cochabamba).

Descriptive notes. 22-23 cm; 112-128 g. Distinctive, large fruiteater. Male has black hood down to chest; upperparts olive-green, large yellow spots on tertials and greater wing-coverts; tail with black subterminal bar, whitish tip; yellow with distinct black barring below; iris variably red, orange or yellow, in N Peru chestnut; bill crimson, sometimes black tip; legs scarlet. Female lacks black hood, and has head concolorous with back, entire underparts barred yellow and black. Juvenile undescribed. Race *viridicauda* differs from nominate in pale yellow to creamy white eyes, and considerably more green on outer tail feathers. Voice. Extremely high, thin, almost hissing "se-e-e-e-e-e-a-a-a-a", descending in pitch, lasting c. 2·5 seconds.
Habitat. Montane forest and forest borders; 1200-3350 m.
Food and Feeding. Apparently only fruit, taken while perched. Rarely joins mixed-species flocks.
Breeding. Fledglings in Jan in Bolivia and Jul in Ecuador. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Uncommon; much less numerous than *P. riefferii*, with which it overlaps extensively in range, altitudinal zone and habitat. Occurs in several protected areas, e.g. Sierra Nevada and Guaramacal National Parks, in Venezeula, Munchique National Park, in Colombia, and Podocarpus National Park, in Ecuador.
Bibliography. Baez *et al.* (1997), Best *et al.* (1997), Bloch *et al.* (1991), Butler (1979), Clements & Shany (2001), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Moynihan (1979), Ortiz & Carrión (1991), Parker (1997), Parker *et al.* (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Walker (2001), Williams & Tobias (1994).

17. Golden-breasted Fruiteater

Pipreola aureopectus

French: Cotinga à poitrine d'or **German**: Goldbrustkotinga **Spanish**: Frutero Pechidorado

Taxonomy. *Ampelis aureo-pectus* Lafresnaye, 1843, "Bogotá", Colombia.
Closely related to *P. jucunda*, *P. lubomirskii* and *P. pulchra*, and all sometimes treated as conspecific, but plumages distinct; geographical range overlap, but without intergradation, between present species and *P. jucunda* in SW Colombia (Nariño). Populations in S part of W Andes included in nominate, but possibly represent a separate, undescribed race. Three subspecies recognized.
Subspecies and Distribution.
P. a. decora Bangs, 1899 - Sierra Nevada de Santa Marta, in N Colombia.
P. a. aureopectus (Lafresnaye, 1843) - Andes of N & W Colombia and Venezuela (E to Lara), and Sierra de Perijá (on Colombia-Venezuela border).
P. a. festiva (Todd, 1912) - coastal range in N Venezuela (Carabobo E to Aragua).

Descriptive notes. 16·5-17·5 cm; one male 46 g, two females 46 g and 60 g. Male nominate race has dusky area on lores and chin, otherwise green above, tertials with small white tips; throat and central breast bright yellow, becoming lemon-yellow on central underparts, not sharply defined from green sides; iris orange-yellow; bill orange or orange-red; legs greenish-grey. Female is similar, but underparts green with yellow streaks. Juvenile undescribed. Race *decora* is smaller than nominate, has bright yellow band across side of neck; *festiva* male is more extensively yellow below. Voice. Main call a high, sibilant phrase up to 3 seconds long, rising and then slowly descending, before rising again at end, then short pause followed by two brief notes, described as "pseéééeeeeeeeeaaaeeeéét tic tic"; sometimes shorter version, as "seeeeeeéé".
Habitat. Humid montane and premontane forest; 800-3100 m.
Food and Feeding. Apparently only fruit. Often seen with mixed-species flocks.
Breeding. Eighteen birds from N Colombia in breeding condition in Jan-Jun, and one in Sept. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Fairly common but somewhat local across N part of range; apparently rare and decidedly local in Colombian Andes. Occurs in Henri Pittier National Park, in Venezuela, and Sierra Nevada de Santa Marta and Salamanca National Parks, in Colombia.
Bibliography. Cracraft (1985), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Rodner *et al.* (2000), Rutgers & Norris (1977), Stotz *et al.* (1996).

18. Orange-breasted Fruiteater

Pipreola jucunda

French: Cotinga jucunda **German**: Orangebrustkotinga **Spanish**: Frutero Pechinaranja

Taxonomy. *Pipreola jucunda* P. L. Sclater, 1860, Cachillacta, Pichincha, Ecuador.
Closely related to *P. aureopectus*, *P. lubomirskii* and *P. pulchra*, and all sometimes treated as conspecific, but plumages distinct; geographical range overlap, but without intergradation, between present species and *P. aureopectus* in SW Colombia (Nariño). Monotypic.
Distribution. W slope of W Andes in Colombia (S from S Chocó) and Ecuador (S to Guayas).

Descriptive notes. 18 cm. Male has glossy black hood, green upperparts, wings and tail; large fiery orange patch on chest extending narrowly to side of neck, bordered below by narrow black line at side; side of breast solid green, rest of underparts yellow, merging with green on flanks; iris light yellow to orange; bill orange to red; legs greenish-grey. Differs from *P. pulchra* in lacking green tinge on head, more fiery orange chest. Female is entirely green above and on chin and throat, rest of underparts streaked yellow and green. Juvenile undescribed. Voice. Extremely high-pitched, hissing "se-e-e-e-e-e-e-e", lasting 2-2·5 seconds; also loud high-pitched "eeest", repeated at short intervals.
Habitat. Occupies montane forest at 600-2300 m, mainly 1100-1300 m; favours very wet mossy forest.
Food and Feeding. Apparently only fruit, taken while perched or in clumsy hover. Occasionally in mixed-species flocks.
Breeding. One record of breeding in wild, in Colombia: female carrying food in Apr (laying probably in Mar), nest concealed within dense clump of vines. In captivity, clutch 2 eggs, incubation 16 or 17 days.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Chocó EBA. Uncommon to locally fairly common; most frequent in optimal habitat of mossy cloudforest in upper tropical zone. Occurs in La Planada Nature Reserve and Río Ñambí Natural Reserve, in Colombia.
Bibliography. Allen (1998), Best *et al.* (1997), Butler (1979), Chapman (1917c), Cracraft (1985), Hilty (1997), Hilty & Brown (1986), Lint & Dolan (1966), Meyer de Schauensee (1945, 1982), Ortiz & Carrión (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rutgers & Norris (1977), Salaman (1994), Samper (1992), Stotz *et al.* (1996), Strewe (2001).

19. Black-chested Fruiteater

Pipreola lubomirskii

French: Cotinga de Lubomirsk **German**: Schwarzkappenkotinga **Spanish**: Frutero Pechinegro

Taxonomy. *Pipreola lubomirskii* Taczanowski, 1879, Quebrada de Sance, 5800 feet [c. 1770 m], Tambillo, Peru.
Closely related to *P. aureopectus*, *P. jucunda* and *P. pulchra*, and all sometimes treated as conspecific, but plumages distinct, and no indication of intergradation. Monotypic.
Distribution. S Colombia (head of Magdalena Valley, and E slope of Andes) and E slope in Ecuador and Peru (S to N Cajamarca, including W slope in Zaña Valley).

Descriptive notes. 17-18 cm. Male has glossy black hood extending down to upper breast, green upperparts, wings and tail; side of breast solid green, rest of underparts yellow, merging with green on flanks; often, a broken black line from chest side to flank; iris yellow; bill orange-red to coral-red; legs greenish-grey to brownish-olive. Differs from *P. jucunda* in lacking orange chest patch; distinguished from similar *P. riefferii* by having no yellow collar, no white on wings, differently coloured iris and legs. Female is entirely green above and on chin to upper breast, rest of underparts streaked yellow and green, bill duller than male's, red to reddish-brown. Juvenile undescribed. Voice. High, very thin, protracted "pseeeeeeeét", stronger towards end; also shorter "pseeet".
Habitat. Montane forest at 1200-2300 m; 1500-2100 m in Ecuador.
Food and Feeding. Apparently only fruit; no details recorded.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Colombian Inter-Andean Slopes EBA and Ecuador-Peru East Andes EBA. Poorly known; apparently rare and local throughout range. Was formerly considered Near-threatened, implying need for further research; probably still merits inclusion in that conservation category. Until recently known only from E slope in N Peru, but during surveys in 1995-1997 found to be present also on W slope, at two sites in Zaña Valley (Cajamarca).
Bibliography. Barnes *et al.* (1997), Best *et al.* (1997), Butler (1979), Chapman (1917c), Cracraft (1985), Davies *et al.* (1994), Hilty & Brown (1986), Kirwan & Hornbuckle (1997c), Meyer de Schauensee (1945, 1982), Negret (2001), Parker *et al.* (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salinas *et al.* (2003), Stotz *et al.* (1996).

20. Masked Fruiteater

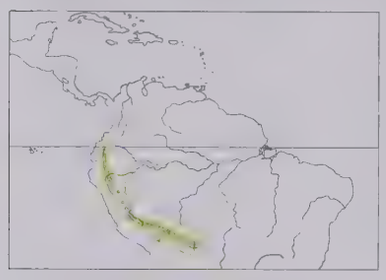
Pipreola pulchra

French: Cotinga masqué **German**: Gelbbrustkotinga **Spanish**: Frutero Enmascarado

Taxonomy. *Euchlornis pulchra* Hellmayr, 1917, Junín, Peru.
Closely related to *P. aureopectus*, *P. jucunda* and *P. lubomirskii*, and all sometimes treated as conspecific, but plumages distinct, and no indication of intergradation. Monotypic.
Distribution. E slope of Andes in Peru (Amazonas S to C Cuzco).

Descriptive notes. 18 cm; male 54-63 g, 2 females 42 g and 63g. Male has black hood tinged greenish (especially on nape), green upperparts, wings and tail; orange-yellow patch on chest extending narrowly to side of neck, bordered below by narrow black line; side of breast solid green, rest of underparts yellow, flanks broadly streaked green; iris yellow; bill red; legs greenish. Distinguished from very similar *P. jucunda* by green tinge on head, less fiery orange on chest. Female is entirely green above, streaked green and yellow below. Juvenile not described. Voice. High-pitched "psee-pseeee".
Habitat. Montane forest; 1500-2250 m.
Food and Feeding. Apparently only fruit; no details.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Ecuador-Peru East Andes EBA. Poorly known. Considered rare to uncommon; as with its congeners, however, it is lethargic and inconspicuous, and knowledge of its true status is very incomplete. Observed frequently at Machu Picchu Historical Sanctuary.
Bibliography. Clements & Shany (2001), Cracraft (1985), Meyer de Schauensee (1982), Parker *et al.* (1982), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1958), Walker (2001).

21. Scarlet-breasted Fruiteater



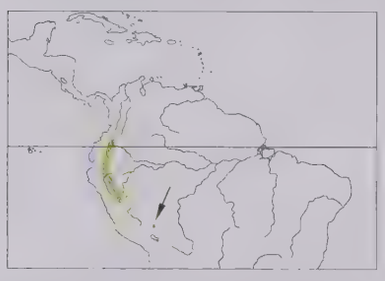
Pipreola frontalis

French: Cotinga chevalier **German**: Scharlachbrustkotinga **Spanish**: Frutero Pechirrojo
Other common names: Bluish-crowned/Bluish-fronted/Chapman's Fruiteater (*squamipectus*)

Taxonomy. *Euchlornis frontalis* P. L. Sclater, 1859, Samaipata, Santa Cruz, Bolivia.
Apparently closely related to *P. chlorolepidota*; speciation probably comparatively recent, but the two now exhibit extensive geographical overlap, although different altitudinal ranges. Race

On following pages: 22. Fiery-throated Fruiteater (*Pipreola chlorolepidota*); 23. Handsome Fruiteater (*Pipreola formosa*); 24. Red-banded Fruiteater (*Pipreola whitelyi*); 25. Scaled Fruiteater (*Ampelioides tschudii*).

squamipectus rather distinct, and separated from nominate by wide gap in N Peru; may perhaps merit full species status. Two subspecies recognized.
Subspecies and Distribution.
P. f. squamipectus (Chapman, 1925) - E slope of Andes from N Ecuador S to N Peru (S to San Martín).
P. f. frontalis (P. L. Sclater, 1859) - E slope from C Peru S to C Bolivia (W Santa Cruz).



Descriptive notes. 15·5-16·5 cm; 39·5-45·3 g (*squamipectus*). Male nominate race has green head, face darker bluish-green, green upperparts, wings and tail, tertials with yellowish tips; large red patch on throat and breast, otherwise largely yellow below, green on flanks; iris pale yellow, sometimes orange-brown; bill and legs orange or orange-red to scarlet. Differs from *P. chlorolepidota* chiefly in colour of underparts. Female differs from male in having green head with some yellow on forehead and throat, breast nearly unmarked green, rest of underparts with more extensive green, giving scaled appearance around belly; also, bill and legs usually duller. Juvenile undescribed. Race *squamipectus* differs from nominate in wider bill, male with darker head and less red on throat, female with entire underparts barred dark green. Voice. A very thin, short "psiii".
Habitat. Montane forest at 1000-2300 m, mainly to 1700 m; has been recorded down to 670 m.
Food and Feeding. Apparently only fruit; no details. Joins mixed-species flocks.
Breeding. Single record from Ecuador. Nest found in Jan, a bowl-shaped structure c. 18 cm in diameter, made externally of moss and lichen, c. 15 m up astride fork of horizontal branch in subcanopy at forest edge; female on nest, but apparently no eggs or young.
Movements. None recorded.
Status and Conservation. Not globally threatened. Poorly known. Considered uncommon to locally fairly common, but inconspicuous behaviour possibly obscures its true status. Occurs in Podocarpus National Park, in Ecuador.
Bibliography. Aversa & Vallely (1999), Best *et al.* (1997), Butler (1979), Cracraft (1985), Jácome (2002c), Mee *et al.* (2002), Meyer de Schauensee (1982), Parker (1997), Parker & Wust (1994), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg (2002), Schulenberg & Wust (1997), Schulenberg *et al.* (2001), Stotz *et al.* (1996).

22. **Fiery-throated Fruiteater**
Pipreola chlorolepidota

French: Cotinga à gorge rouge **German**: Orangekehlkotinga **Spanish**: Frutero Gorgirrojo

Taxonomy. *Pipreola chlorolepidota* Swainson, 1838, vicinity of Moyobamba, San Martín, Peru.
Apparently closely related to *P. frontalis*; speciation probably comparatively recent, but the two now exhibit extensive geographical overlap, although different altitudinal ranges. Monotypic.
Distribution. E slope of Andes from S Colombia (Cauca, W Caquetá) S to C & SE Peru (S to Pasco, also isolated record in extreme E Puno).

Descriptive notes. 12-13 cm; one male 28 g, one female 31 g. The smallest fruiteater. Male has green head, often some dusky on face, green upperparts, wings and tail, small white tips on remiges and rectrices, large and conspicuous white tips on tertials; yellow to orange bib, becoming red on chest; rest of underparts green, yellowish on central belly; iris cream or greyish-white; bill orange with black tip; legs orange. Female lacks orange bib, is barred green and yellow below, more yellow on throat and more green on breast, has duskier bill. Voice. Very short, high-pitched "tsi".
Habitat. Humid forest of Andean foothills; 600-1500 m, in small numbers down to 300 m.
Food and Feeding. Little known. Recorded at fruit trees; probably wholly or predominantly frugivorous, like congeners. Follows mixed-species flocks.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Poorly known. Rare in most of range, locally uncommon at a few sites; recorded in only three places in Colombia. Possibly less rare than it appears to be; very inconspicuous behaviour may obscure its true status. Foothill forests within its range are under severe pressure, and many already converted to agriculture and cattle pasture; logging and other commercial activities (e.g. mining, oil exploration) are further threats. Occurs in Sangay National Park, in Ecuador.
Bibliography. Balchin & Toyne (1998), Butler (1979), Canaday (2002b), Cracraft (1985), Hilty & Brown (1986), Mee *et al.* (2002), Meyer de Schauensee (1982), Parker *et al.* (1996), Pearman (1994a), Restrepo *et al.* (2002), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg & Servat (2001), Stattersfield & Capper (2000), Stotz *et al.* (1996), Zimmer (1930).

23. **Handsome Fruiteater**
Pipreola formosa

French: Cotinga magnifique **German**: Weißfleckenkotinga **Spanish**: Frutero Hermoso

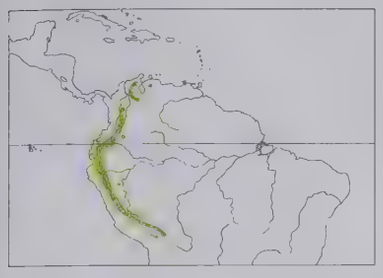
Taxonomy. *Ampelis formosa* Hartlaub, 1849, Caracas, Venezuela.
Three subspecies recognized.
Subspecies and Distribution.
P. f. formosa (Hartlaub, 1849) - mountains of N Venezuela from Falcón and Yaracuy E to Distrito Federal and Miranda.
P. f. rubidior (Chapman, 1925) - coastal mountains of N Venezuela in Anzoátegui, Sucre and Monagas.
P. f. pariae Phelps, Sr & Phelps, Jr, 1949 - mountains of Paria Peninsula, in NE Venezuela.
Descriptive notes. 16-18 cm; male 43-49 g, 2 females 41 g and 45 g. Rather distinctive, with prominent white on tertials. Male nominate race has black head and throat, green upperparts, wings and tail, contrasting large white tips of tertials; orange-red on chest becoming yellow downwards, flanks greenish; iris orange-yellow to brown; bill orange-red; legs greyish-olive. Female has head and throat green, distinct yellow crescent-shaped chest patch, rest of underparts finely barred green and yellow. Juvenile undescribed. Race *rubidior* has redder chest and smaller wing spots than nominate, female with dark-barred yellowish throat; *pariae* has even brighter and more extensive red on chest. Voice. A high, thin "pik" and "ti-ti-ti-ti-ti-ti..."; song a high "peeéé-eeeeeee-e-e-e-e", loudest near start, slowing at end.

Habitat. Humid to wet premontane and montane forest; 800-2200 m.
Food and Feeding. Mostly small fruits, taken either while perched or in short upward sally with momentary hover. Sometimes briefly joins mixed-species flocks.
Breeding. No direct information. Moult (presumably post-breeding) begins mainly May-Jul, indicating breeding in early months of year.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Caripe-Paria Region EBA and Cordillera de la Costa Central EBA. Fairly common to common, and the most numerous of the five Venezuelan fruiteaters; common in Paria Peninsula (race *pariae*). Occurs in Henri Pittier National Park. Often markedly tame, allowing close approach.
Bibliography. Bond *et al.* (1989), Cracraft (1985), Hilty (2003), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Rodner *et al.* (2000), Stotz *et al.* (1996), Visbal *et al.* (1996), Wetmore (1939).

24. **Red-banded Fruiteater**
Pipreola whitelyi

French: Cotinga cordon-rouge **German**: Brustbandkotinga **Spanish**: Frutero Degollado

Taxonomy. *Pipreola whitelyi* Salvin and Godman, 1884, Cerro Roraima, Venezuela.
Two subspecies recognized.
Subspecies and Distribution.
P. w. whitelyi Salvin & Godman, 1884 - extreme SE Venezuela and adjacent Guyana (on mountains Roraima, Twek-quay and Kowa).
P. w. kathleenae J. T. Zimmer & Phelps, Sr, 1944 - tepuis W of Cerro Roraima, in SE Venezuela.



Descriptive notes. 16·5-17 cm. The most distinctive species in genus. Male nominate race has tawny-buff to rufous lowermost forehead, supercilium and cheek; rather dark greyish-green above, wings and tail contrastingly rufous-brown; red crescent-shaped band across chest, becoming tawny on neck side; rest of underparts grey, undertail-coverts ochre; iris orange-red; bill and legs red. Female is duller above than male, underparts entirely yellowish-white with blackish streaks, has yellowish eyes, duller bill and legs. Juvenile is conspicuously spotted on upperparts. Race *kathleenae* differs from nominate in having more extensive yellowish on forehead, female with blacker stripes below. Voice. Drawn-out, very high and thin "pss-ee-ee-ee-ee-ee-ee", c. 2-3 seconds long, given at long intervals; also high, thin "ti" notes, often in short series, when excited.
Habitat. Montane forest; 1300-2250 m. Prefers mossy forest, also dense stunted secondary growth dominated by melastome (Melastomataceae) trees.
Food and Feeding. Apparently only fruit; no details. Sometimes joins mixed-species flocks.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Considered rare to uncommon, but is easily overlooked; in Venezuela, possibly most numerous on Cerro Ptari (race *kathleenae*). Much of its range is difficult of access, and not at present under threat. Occurs in Canaíma National Park, in Venezuela.
Bibliography. Barnett *et al.* (2002), Chapman (1931), Cracraft (1985), Hilty (2003), Mayr & Phelps (1967), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Prum (1988), Ridgely & Tudor (1994), Rodner *et al.* (2000), Snyder (1966), Stotz *et al.* (1996), Zimmer & Phelps (1944).

Genus *AMPELIOIDES* J. Verreaux, 1867

25. **Scaled Fruiteater**
Ampelioides tschudii

French: Cotinga écaillé **German**: Schuppenkotinga **Spanish**: Frutero Escamoso

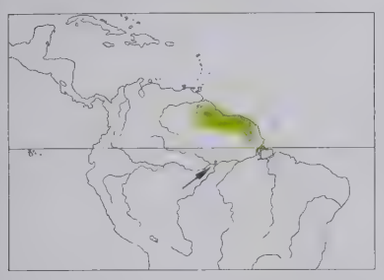
Taxonomy. *C[otinga] Tschudii* G. R. Gray, 1846, Pangos, east of Tarma, Junín, Peru.
Possibly most closely related to *Pipreola*. Monotypic.
Distribution. Sierra de Perijá (on Colombia-Venezuela border), and locally in Andes from Venezuela (Lara, SE Tachirá) and N Colombia S to NW Bolivia (La Paz, W Beni); also coastal ranges of Ecuador, in W Esmeraldas and Guayas (Loma Alta), in W Ecuador; also, locally, E of Andes in Colombia (Sierra de Macarena) and Peru (Cordillera Azul).
Descriptive notes. 19-20 cm; male 74-95 g, female 71·5-80 g. Distinctive cotingid, with bill broad at base, upper mandible somewhat swollen laterally, tarsus without scutellation along posterior surface. Male has glossy black cap to nape, auriculars and gape; lores whitish, moustachial stripe yellowish-white, joining pale yellow hindcollar; upperparts blackish, scaled olive, yellow tips on some uppertail-coverts; wings blackish, large olive tips of tertials, entirely olive greater

wing-coverts (conspicuous wide wingband), median and lesser coverts narrowly scaled olive, white outer edges of some outer primaries; short tail mostly olive, subterminal black bar, outer rectrices black, narrow creamy white tips; chin and throat whitish, weakly scaled, separated from moustachial area by ill-defined blackish streak; variable black band on lower neck side and chest side; rest of underparts pale yellow, broadly scaled with olive; iris amber-yellow to golden-yellow, sometimes with red inner ring; upper mandible mostly black, lower mandible pale olive to greyish; legs olive-grey or bluish-grey, dull yellow soles. Female has black of head replaced by olive, collar and face markings less bold, upperparts and wing-coverts less extensively blackish, thus more olivaceous appearance above, scaling below blackish, more contrasting, eyes duller, sometimes olive-green. Immature has feathers of upperparts extensively pale-tipped. Voice. Territorial song a series of rather loud, downward-inflected whistles, initially rising, somewhat like call of raptor (Accipitridae). Rattling wing noise in flight.

Habitat. Humid montane forest; mostly at 900-2700 m; 575-750 m in W Ecuador (Loma Alta).
Food and Feeding. Mainly fruit and insects; arboreal snails (*Plekokeilas*) also eaten, apparently regularly in an area in Ecuador. Fruits in stomach contents measured 10 × 10 mm; bill shape suggests that fruits taken are large in relation to bird's size; male seen to feed immature with orange-coloured fruit c. 2·5 cm in diameter, also to regurgitate black fruits half the size of its own bill. Searches for insects along horizontal epiphyte-covered branches. Arboreal snails taken from underside of tree branches in upward sally, beaten against branch to remove outer lip of aperture, then swallowed whole. Regularly accompanies mixed-species foraging flocks.
Breeding. Male feeding immature in mid-Nov in Bolivia. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Generally rare or uncommon; rather few records from Venezuela; locally more numerous in Ecuador. Although more active than *Pipreola* fruiteaters, is also more wary and hence difficult to see; likely to be similarly under-recorded. Occurs in several protected areas, including La Planada Nature Reserve and Río Ñambí Natural Reserve, in Colombia, and Madidi National Park, in Bolivia.
Bibliography. Allen (1998), Aveledo & Pons (1952), Becker & López (1997), Best *et al.* (1997), Butler (1979), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty (1997, 2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Parker *et al.* (1980), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ryan (2000), Salaman (1994), Schulenberg & Servat (2001), Schulenberg *et al.* (2001), Stotz *et al.* (1996), Strewe (2000b), Williams (2002a), Williams & Tobias (1994), Zimmer (1930).

PLATE 4

inches 4
cm 10



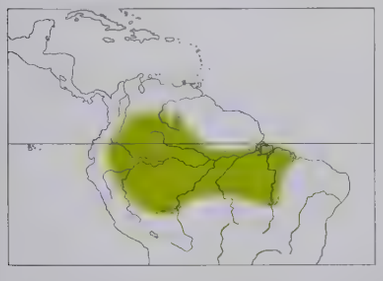
Genus *IODOPLEURA* Lesson, 1839

26. **Dusky Purpletuft**

Iodopleura fusca

French: Cotinga brun **German**: Braunkopf-Zwergkotinga **Spanish**: Cotinguita Oscuro
Other common names: Dusky Cotinga

Taxonomy. *Ampelis fusca* Vieillot, 1817, Cayenne.
Genus has been suggested, on basis of morphological analysis, as possibly belonging to an assemblage containing *Laniisoma* and genera currently placed in Pipridae (*Schiffornis*) and Tyrannidae (*Laniocera*, *Xenopsaris*, *Pachyramphus*); traditional placement within present family considered preferable, pending further study. Species is closely related to, and forming a superspecies with, *I. isabellae*; possibly conspecific, but differences comparable to those between other species pairs within family and treatment as separate species seems justified. Monotypic.
Distribution. E & SE Venezuela, the Guianas, and adjacent N Brazil (Roraima and probably farther S, to Manaus area, also Amapá).



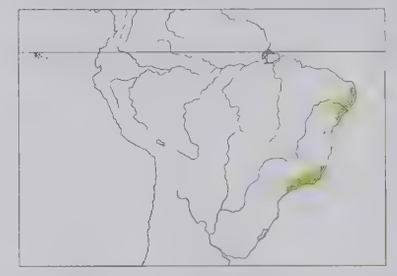
Descriptive notes. 11 cm; one male 15·3 g. Small cotingid with relatively long hirundinid-like wings, short tail extending only 5-10 mm beyond tail-coverts, wide bill slightly expanded at base, hooked at tip. Male slaty blackish above, white band on rump; underparts smoky brown, white centrally, with small tuft of violet feathers on upper flank; iris dark brown; upper mandible black, lower mandible lead-grey; legs dark lead-grey. Smaller than *I. isabellae*, much darker, lacks white on head, throat and flanks. Female has flank tuft white. Juvenile has conspicuously white-tipped feathers; moults into plumage indistinguishable (or nearly so) from full adult plumage. Voice. Soft trilled notes and high, thin notes, similar to those of *I. isabellae*.
Habitat. Canopy and borders of humid forest; to 500 m.
Food and Feeding. Insects, taken in flight sallies from treetops; also fruit. No further details.
Breeding. Pair with fledglings in Feb in Venezuela. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Poorly known. Considered uncommon or rare, but probably under-recorded owing to difficulty of observation of small treetop birds in areas of unbroken forest. Occurs in Imataca Forest Reserve and El Dorado, in Venezuela.
Bibliography. Cohn-Haft *et al.* (1997), Cracraft (1985), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Meyer de Schauensee (1982), Prum (1988), Ridgely & Tudor (1994), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992).

27. **White-browed Purpletuft**

Iodopleura isabellae

French: Cotinga d'Isabelle **Spanish**: Cotinguita Cejiblanco
German: Weißbrauen-Zwergkotinga
Other common names: White-browed Cotinga

Taxonomy. *Iodopleura Isabellae* Parzudaki, 1847, San Carlos, Río Negro, south Venezuela.
Genus has been suggested, on basis of morphological analysis, as possibly belonging to an assemblage containing *Laniisoma* and genera currently placed in Pipridae (*Schiffornis*) and Tyrannidae (*Laniocera*, *Xenopsaris*, *Pachyramphus*); traditional placement within present family considered preferable, pending further study. Species is closely related to, and forming a superspecies with, *I. fusca*; possibly conspecific, but differences comparable to those between other species pairs within family and treatment as separate species seems justified. Two subspecies recognized.
Subspecies and Distribution.
I. i. isabellae Parzudaki, 1847 - W Amazon Basin and upper R Orinoco drainage in S Venezuela, SE Colombia, E Ecuador, E Peru, extreme N Bolivia (Pando), and Brazil (E to W Pará).
I. i. paraensis Todd, 1950 - E Amazon Basin in Brazil (E Para E from R Tocantins, S to N Goiás).



Descriptive notes. 11-12 cm; 19·8-20·2 g. Small cotingid with relatively long hirundinid-like wings, short tail extending only 5-10 mm beyond tail-coverts, wide bill slightly expanded at base, hooked at tip. Male nominate race has white lores, postocular stripe and moustachial area; rest of head, and upperparts, wings and tail, blackish-brown, white band on rump; underparts white, dusky brown on breast side and barring on flanks, small tuft of violet feathers on upper flank; iris dark brown; upper mandible black, lower mandible lead-grey; legs dark lead-grey. Female differs from male in having flank tuft white. Juvenile has feathers conspicuously white-tipped; moults into plumage indistinguishable (or nearly so) from full adult plumage. Race *paraensis* is darker above than nominate, and flanks more barred and mottled. Voice. Variety of mostly weak, high-pitched notes, mostly trilled or tittering, e.g. "tre-e-ed" and repeated rising "ueeéé"; also soft "sr'r'r" trills in series, weak "jee-jee-jee" and thin "ti-ti-ti-ti-ti-ti-ti" rattle.
Habitat. Canopy and borders of humid forest and secondary woodland; mostly below 500 m, in small numbers up to 900 m.
Food and Feeding. Insects, taken in flight sallies from treetops; also much fruit, including mistletoe berries (Loranthaceae), usually taken during brief hover, at times from perched position. Usually in pairs, or in small groups.
Breeding. One nest and records of dependent juveniles indicate laying in Sept-Dec in E Brazil (Belém area). Only nest found was a minute cup-shaped structure of vegetable fibres, thickly coated on outside with spider web, and fixed by spider web to slender horizontal branch 18-19 m up in crown of dead tree. No further information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Generally uncommon, but probably under-recorded owing to difficulty of observation of small treetop birds in areas of unbroken forest. Occurs in several protected areas, e.g. Cuyabeno Reserve (Ecuador) and Manu National Park and Biosphere Reserve, and Tambopata-Candamo Reserved Zone (Peru).
Bibliography. Allen (1995), Angehr & Aucca (1997), Bates *et al.* (1998), Best *et al.* (1997), Brooks *et al.* (1999), Butler (1979), Camargo & Camargo (1964), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Oren & Parker (1997), Ortiz & Carrión (1991), Poulsen (1992), Prum (1988), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1979a), Stotz *et al.* (1996), Terborgh *et al.* (1984), Willard *et al.* (1991), Zimmer & Hilty (1997), Zimmer *et al.* (1997).

28. **Buff-throated Purpletuft**

Iodopleura pipra

French: Cotinga manakin **German**: Fahlkehl-Zwergkotinga **Spanish**: Cotinguita Pipra
Other common names: Buff-throated Cotinga

Taxonomy. *Pardalotus pipra* Lesson, 1831, Sri Lanka; error = Rio de Janeiro, Brazil.
Genus has been suggested, on basis of morphological analysis, as possibly belonging to an assemblage containing *Laniisoma* and genera currently placed in Pipridae (*Schiffornis*) and Tyrannidae (*Laniocera*, *Xenopsaris*, *Pachyramphus*); traditional placement within present family considered preferable, pending further study. Two subspecies recognized.
Subspecies and Distribution.
I. p. leucopygia Salvin, 1885 - coastal NE Brazil in Paraíba, Pernambuco, Alagoas and Bahia.
I. p. pipra (Lesson, 1831) - coastal E Brazil in Espírito Santo, Rio de Janeiro and São Paulo.

Descriptive notes. 9·5 cm; 10 g. Small cotingid with relatively long hirundinid-like wings, short tail extending only 5-10 mm beyond tail-coverts, wide bill slightly expanded at base, hooked at tip. Male nominate race is grey above, darker on crown, sometimes some white on rump; wings and tail duskier; cinnamon-buff on throat, chest and undertail-coverts, grey side of breast, rest of underparts white with grey barring, small tuft of violet feathers on upper flank; iris dark brown; upper mandible black, lower mandible lead-grey; legs dark lead-grey. Female lacks violet tuft on flank. Juvenile has conspicuous white feather tips. Race *leucopygia* has white rumpband more developed, also purer (less greyish) and more extensive buff area on throat than nominate. Voice. High-pitched, faint "se-se-see", in flight sometimes repeated so rapidly as to become a short orthopteran-like trill; also a double whistle, "seee, fee".
Habitat. Humid forest, secondary woodland and cacao plantations; to 1000 m.
Food and Feeding. Mainly mistletoe berries (Loranthaceae), some other fruits; also small insects. Forages mainly high in trees, especially large fine-leaved leguminous trees often holding mistletoe clumps. Picks insects off vegetation or catches them in air.
Breeding. Recorded in Jul-Oct; two records of laying in Jul, in austral winter (unusual, but supported by records of moult beginning Aug-Sept); singing male in Dec in Espírito Santo. Nest a tiny cup, felted and whitish with darker blotches (probably of lichens), saddled on small peripheral twig c. 18 m above ground on high branch of leafless tree. Clutch 1 egg; incubation and fledging periods not known.
Movements. Little understood; probably some vertical seasonal movement. Found "migrating" in small flocks in Nov (austral summer) at 900 m in Espírito Santo, but breeding recorded at sea-level in winter.
Status and Conservation. ENDANGERED. Restricted-range species: present in Atlantic Slope of Alagoas and Pernambuco EBA and Atlantic Forest Lowlands EBA. Rare, and range highly fragmented. Recorded from only few sites. Only in recent years found to be surviving in some areas in SE Brazil, and small population discovered in NE Brazil; existence of N race *leucopygia* was for long obscured by mislabelling of the two specimens on which it was based as having originated from Guyana. Future survival of both races threatened by extensive destruction of lowland Atlantic Forest; the fact that it occurs in mainly lowland coastal forest renders it even more at risk than was previously thought, as this habitat is being cleared at a rapid rate. Occurs in Serra dos Órgãos National Park and Desengano and Serra do Mar State Parks; also in Ubatuba Experimental Station (São Paulo). Protection of forest at Murici (Alagoas) would greatly benefit this and other globally threatened species, e.g. *Carpornis melanocephala*.
Bibliography. de Almeida & Teixeira (1997), Anon. (1997c, 2002b), Camargo & Camargo (1964), Collar & Andrew (1988), Collar *et al.* (1992), Cracraft (1985), Descourtilz (1983), Forrester (1993), Mallet-Rodrigues & Marinho (2003), Mendoça & Gonzaga (2000), Meyer de Schauensee (1982), Prum (1988), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Teixeira *et al.* (1990), Tobias *et al.* (1993), Wege & Long (1995), Willis & Oniki (1988a).

Genus *CALYPTURA* Swainson, 1832

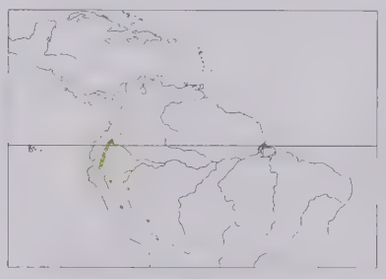
29. **Kinglet Calyptura**

Calyptura cristata

French: Cotinga roitelet **German**: Goldhähnchenkotinga **Spanish**: Cotinguita Reyezuelo
Other common names: Kinglet Cotinga

Taxonomy. *Pardalotus cristatus* Vieillot, 1818, Rio de Janeiro, Brazil.
Relationships uncertain. Monotypic.
Distribution. Rio de Janeiro area of SE Brazil.

Descriptive notes. 7·5-8 cm. Tiny, much the smallest cotingid, reminiscent of a kinglet (*Regulus*) except for conical bill with strongly arched culmen, very short tail. Male has black-bordered large orange-red crown patch, feathers somewhat elongated; bright olive above, rump yellow; wings and tail mostly dusky, tips of greater and median wing-coverts with obvious white bars, tertials also tipped white; underparts yellow, olive wash on breast; bare-part colours not recorded, bill and legs apparently dark. Female has reduced patch on crown. Juvenile undescribed. Voice. Not recorded.
Habitat. Forest and second-growth woodland, probably to c. 900 m; recently rediscovered at c. 550 m.
Food and Feeding. Insects and small fruits; according to old account, especially berries of a solanaceous shrub.
Breeding. No information.
Movements. None recorded.
Status and Conservation. CRITICAL. Restricted-range species: present in Atlantic Forest Lowlands EBA. Had not been recorded for over a century, and presumed extinct by many ornithologists. Remarkably, rediscovered in Oct 1996 on edge of Serra dos Órgãos National Park, c. 60 km N of city of Rio de Janeiro; two individuals observed on several occasions during 27th-30th Oct; despite intense searches at same and suitable nearly sites, no further sightings made. Believed to have been not uncommon in 19th century, as c. 50 specimens exist in museum collections (last one dated c. 1890); virtually all forest below 1000 m in the area has since been destroyed. Full protection of remaining lowland forest in the vicinity considered a priority conservation measure. Intensive surveys will, it is hoped, result in further observations of this almost unknown cotingid.
Bibliography. Collar & Andrew (1988), Cracraft (1985), Descourtilz (1983), Forrester (1993), Gonzaga (1997), King (1978/79), Meyer de Schauensee (1966, 1982), Pacheco & da Fonseca (2000, 2001), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1972, 1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996).



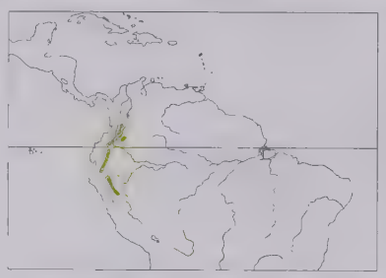
Genus *SNOWORNIS* Prum, 2001

30. **Grey-tailed Piha**

Snowornis subalaris

French: Cotinga à queue grise **German**: Grauschwanzpiha **Spanish**: Guardabosques Coligrís
Other common names: Grey-tailed Cotinga

Taxonomy. *Lipaugus subalaris* P. L. Sclater, 1861, River Napo, Ecuador.
Closely related to *S. cryptolophus*; both formerly placed in genus *Lipaugus*, but morphological study and recent analysis of DNA sequences indicate only remote relationship to latter; previously suggested placement in genus *Lathria*, but that name unavailable. Monotypic.
Distribution. E slopes of Andes locally in S Colombia, Ecuador, and Peru (San Martín, Pasco, S Madre de Dios).



Descriptive notes. 23·5 cm; 1 male 86·3 g, 2 females 81·8 g and 82 g. Male has semi-concealed black feathers on crown; otherwise olive-green above, greyer on wings, grey on rump and tail; underparts paler olive-green, narrow pale shaft streaks on throat and breast, grey below; underwing-coverts yellow; iris dark brown, pale orbital ring; bill dark horn, paler base of lower mandible; legs grey. Differs from *S. cryptolophus* in relatively shorter legs, broader bill, grey tail and lower underparts, yellower underwing-coverts. Female lacks black on crown. Juvenile undescribed. Voice. Clear, ringing 2-note whistle, "churrrrrr-ee", delivered at long intervals; less often a shorter version, "chreeee".
Habitat. Humid forest in Andean foothills; 500-1400 m.
Food and Feeding. Insects and fruit. Insects taken from foliage in flight sallies, and by hover-gleaning; method of taking fruit not recorded. Rarely, associates with mixed-species flocks.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. A very little-known species. Apparently rare to uncommon, and patchily distributed. In mid-1980s, found to be locally quite numerous in its only known S Peruvian locality, in Madre de Dios. Probably merits conservation status of Near-threatened.
Bibliography. Balchin & Toyne (1998), Best *et al.* (1997), Butler (1979), Canaday (2002c), Cracraft (1985), Dick (1991), Meyer de Schauensee (1982), Parker (1997), Pearman (1994a), Prum (2001), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg (2002), Schulenberg & Servat (2001), Schulenberg *et al.* (2001), Stotz *et al.* (1996).

31. **Olivaceous Piha**

Snowornis cryptolophus

French: Cotinga olivâtre **German**: Gelbbauchpiha **Spanish**: Guardabosques Oliváceo
Other common names: Olivaceous Cotinga

Taxonomy. *Lathria cryptolopha* P. L. Sclater and Salvin, 1877, Monji, Ecuador.
Closely related to *S. subalaris*; both formerly placed in genus *Lipaugus*, but morphological study and recent analysis of DNA sequences indicate only remote relationship to that genus; previously suggested placement in genus *Lathria*, but that name unavailable. Two subspecies recognized.
Subspecies and Distribution.
S. c. mindoensis (Hellmayr & Seilern, 1914) - W Andes of Colombia (S from Antioquia) and NW Ecuador (Pichincha).
S. c. cryptolophus (P. L. Sclater & Salvin, 1877) - E Andes of Colombia (S from head of Magdalena Valley) and Ecuador, and E & C Andean slopes of Peru (S to Huánuco).

Descriptive notes. 23·5-25 cm; two males 83 g and 85 g. Has semi-concealed black feathers on crown; otherwise olive-green above, greyer on wings; underparts olive-green, paler on chin and yellower on belly, sometimes a few pale shaft streaks on throat and breast; underwing-coverts dull yellowish; iris dark brown, pale orbital ring; bill dark horn, paler base of lower mandible; legs grey. Differs from *S. subalaris* in relatively longer legs, narrower bill, greener tail, more green below, duller underwing. Sexes alike. Juvenile undescribed. Race *mindoensis* is slightly smaller than nominate, has concealed bases of black crown feathers extensively creamy white (instead of brown). Voice. No information.
Habitat. Montane forest at 570-2300 m; 1000-1800 m in Ecuador.
Food and Feeding. Fruits and insects, taken in short flight sally. Occasionally accompanies mixed-species foraging flocks.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Generally scarce to uncommon, and apparently local. Widespread destruction of forest at subtropical levels has certainly led to fragmentation and reduction of population of W race *mindoensis*. Occurs in La Planada Nature Reserve and Río Ñambí Natural Reserve, in Colombia.
Bibliography. Allen (1998), Best *et al.* (1997), Butler (1979), Hilty & Brown (1986), Mee *et al.* (2002), Meyer de Schauensee (1945, 1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg (2002), Schulenberg *et al.* (2001), Stotz *et al.* (1996), Traylor (1958), Zimmer (1930, 1936a).

Genus *LIPAUGUS* Boie, 1828

32. **Dusky Piha**

Lipaugus fuscocinereus

French: Piauhau sombre **German**: Andengraupiha **Spanish**: Guardabosques Oscuro

Taxonomy. *Querula fusco-cinerea* Lafresnaye, 1843, "Bogotá".
Probably closest to *L. weberi* and *L. uropygialis*. Monotypic.
Distribution. E, C & N end of W Andes of Colombia, and E slope in Ecuador and extreme N Peru (Cerro Chinguela).

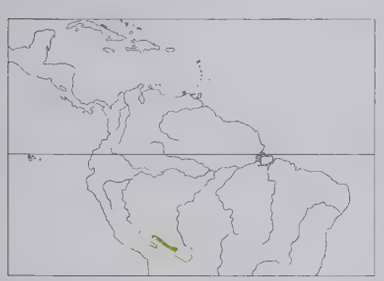
Descriptive notes. 33 cm; 120-138 g. Largest member of genus, with rather long tail. Male is grey, duskier on wings and tail; has primaries 5-7 modified, with barbs of middle part of outer webs elongated, stiffened and not interlocking; paler grey below, with brownish wash from breast downwards; iris dark brown; bill dark brown or blackish, paler base of lower mandible; legs grey. Female is like male, but lacks modification of primaries. Immature has rufous-tipped wing coverts, presumably retained from juvenile plumage. Voice. Loud "pee-a-weeee" or "pee-a-weeee-a-weeee", last syllable slurring down scale. Loud wing noise made in display.
Habitat. Montane forest and adjacent second growth; mostly 2000-3000 m.
Food and Feeding. Feeds on fruit, which is taken in brief flight sally; probably also eats insects. In E Andes of Colombia, fruits of eight plant families recorded in diet, Chloranthaceae (*Hedyosmum*) numerically most important. Often in small groups; regularly accompanies mixed-species foraging flocks.
Breeding. No information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Uncommon to scarce, and patchily distributed. Numbers have certainly been reduced by extensive deforestation of Andes at subtropical and temperate levels.
Bibliography. Best *et al.* (1997), Butler (1979), Chapman (1917c), Cracraft (1985), Fjeldså & Krabbe (1990), Hilty & Brown (1986), López (2000), Meyer de Schauensee (1982), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Renjifo (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996).

33. **Chestnut-capped Piha**

Lipaugus weberi

French: Piauhau de Weber **Spanish**: Guardabosques Antioqueño
German: Braunkappen-Graupiha

Taxonomy. *Lipaugus weberi* Cuervo *et al.*, 2001, La Forzosa, Antioquia, Colombia.
Probably most closely related to *L. fuscocinereus*. Monotypic.
Distribution. N & NE slopes of Cordillera Central of Colombia (E of Nechí Valley, in Antioquia).



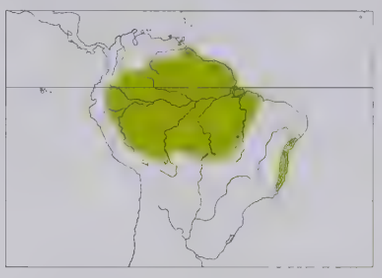
Descriptive notes. 24-25 cm; 72 g. Male has chestnut crown; plumage otherwise slate-grey, slightly paler below, with pale cinnamon undertail-coverts; primaries 6 and 7 modified, with barbs of outer webs stiffened and not interlocking; iris dark brown, orbital ring yellowish; bill blackish; legs grey. Female is like male, but primaries not modified. Juvenile is similar to adult, but with secondaries and outer primaries broadly fringed rufous. VOICE. Loud piercing "sreeck", rising in pitch and then abruptly descending, typically repeated at 1-second intervals; also, relatively quiet, nasal "gluck-gluck", apparently as contact or alarm.
Habitat. Primary premontane wet forest, including moderately disturbed forest; large cloudforests favoured; apparently absent from young secondary forest. Recorded at 1400-1900 m.
Food and Feeding. Mainly fruits, also occasionally large invertebrates. Fruits of several plant families recorded, including especially Lauraceae, also Rubiaceae, Myrsinaceae and Melastomataceae. Food items usually taken in short flight sallies; sometimes detaches fruits by making a twisting aerial "pirouette", occasionally plucks them while perched. Occasionally accompanies mixed-species foraging flocks.
Breeding. Season probably in first half of year; recently fledged young in early Jun, and male with almost completed moult and female in full wing and tail moult both in late Aug. Possible lek observed in Jul, three birds together, two of which chasing one another. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Conservation status not formally assessed, as this species was not discovered until as recently as 1999 and officially described in 2001. Appeared then to be fairly common within a narrow belt of very humid premontane forest in C range of Colombian Andes, where it had been recorded at five localities; estimated extent of range less than 100 km^2, and total population estimated at fewer than 2500 individuals; detected at a further 20 sites in the area in 2002. Intensive observations revealed that, in small forest fragments, this newly discovered cotingid exhibited high degree of morphological asymmetry (apparently related to lower survival rate, reduced fitness and poorer aerodynamics), indicating that it is one of the species most adversely affected by forest fragmention. In view of current rate of forest clearance and degradation within its very small range, recommendation has been made that this species be accorded conservation status of Endangered, or even Critical. An important 320-ha forest block at La Forzosa (type locality), which harbours populations of several other globally threatened bird species, is now formally protected. More complete investigation of this piha's present range desirable, and establishment of additional protected areas in this ornithologically poorly known region an urgent priority.
Bibliography. Anon. (2001b, 2001c), Cuervo & Renjifo (2002), Cuervo *et al.* (2001), Lowen (2002a, 2003), Stotz *et al.* (1996).

34. Scimitar-winged Piha

Lipaugus uropygialis

French: Piauhau à faucilles **German**: Rotbürzelpiha **Spanish**: Guardabosques Alicurvo
Other common names: Scimitar-winged Cotinga

Taxonomy. *Lathria uropygialis* P. L. Sclater and Salvin, 1876, Tilotilo, 8000 feet [c. 2440 m], La Paz, Bolivia.
Previously placed in a monotypic genus, *Chirocylla*, on basis of extreme modification of wing feathers; in other respects, however, similar to *L. fuscocinereus*, and probably closest to that species. Monotypic.
Distribution. E slope of Andes in extreme SE Peru (E Puno) and Bolivia (La Paz, Cochabamba).



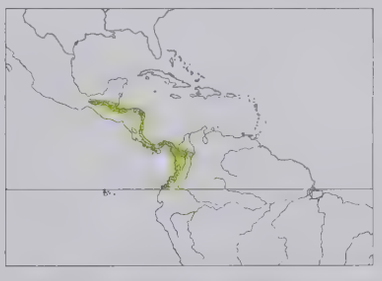
Descriptive notes. 30 cm; one male 116 g, one female 135 g. Male is grey above, paler grey below, with rufous-chestnut rump, lower flanks and undertail-coverts; primaries highly modified, strongly recurved and attenuated, also of unusual relative lengths, P5-P8 each progressively shorter than preceding one, P9 and P10 much longer; iris dark red-brown; bill blackish, dark horn below; legs plumbeous. Female is like male, possibly slightly larger, with primaries much less modified. Juvenile undescribed. VOICE. Uncertain; excited "wheeo, wheeo, whee-wheé, whee-wheé, whee-wheé", with variants, believed made by individual of this species (calling bird not seen).
Habitat. Montane forest and forest borders; 1800-2750 m.
Food and Feeding. Berries and fruits; probably also insects, but information lacking. Has been recorded with mixed-species flocks.
Breeding. No information. Two males in wing moult (presumably post-breeding), one in late stage at end Jul, other in very early stage in late Nov.
Movements. None recorded.
Status and Conservation. VULNERABLE. Restricted-range species: present in Bolivian and Peruvian Upper Yungas EBA. Rare, and very seldom seen; has small total range, within which has been found at only very few localities. Has apparently undergone severe population decline in areas of disturbed forest, and clearance and fragmentation of habitat continue to be a major threat; nevertheless, it exists in some large expanses, still little explored. Suggestion that it requires old-growth forest during at least part of the year would, if correct, render it more susceptible than other yungas species to effects of selective and small-scale logging. Recorded in Cotapata and Carrasco National Parks, in Bolivia.
Bibliography. Fjeldså & Krabbe (1990), Hennessey & Gómez (2003), Hennessey, Herzog & Sagot (2003), Meyer de Schauensee (1982), Remsen & Traylor (1989), Remsen *et al.* (1982), Ridgely & Tudor (1994), Snow (1982), Stattersfield & Capper (2000), Stotz *et al.* (1996).

35. Screaming Piha

Lipaugus vociferans

French: Piauhau hurleur **German**: Tiefland-Graupiha **Spanish**: Guardabosques Gritón
Other common names: Greenheart Bird

Taxonomy. *Muscicapa vociferans* Wied, 1820, Fazenda Pindoba, north of Caravellos, Bahia, Brazil.
Analysis of feather proteins has suggested possible relationship between this species and genus *Tijuca* (especially *T. atra*). Despite increase in size and weight from N to SW of range, and presence of isolated population in E Brazil, variation considered insufficient to merit naming of geographical races. Monotypic.
Distribution. E & S Venezuela (SE Sucre, Delta Amacuro, Bolívar, Amazonas), the Guianas, and forested parts of whole of Amazon Basin (W from edge of Andes) from Ecuador, Colombia and Brazil S to Bolivia; also coastal E Brazil (Pernambuco S to Espírito Santo).



Descriptive notes. 24-28 cm; male average 67·2 g and female 70·6 g (Surinam), male average 81·9 g and female 82·6 g (Peru). Dullest and most uniform-coloured cotingid, but vocally outstanding. Plumage is grey overall, duskier on wings and tail, slightly paler below, especially on throat and belly; iris brown or brown-grey; bill dark brown or blackish, paler base of lower mandible; legs dark grey to greenish-grey. Sexes alike. Juvenile has rufous upperwing-coverts and rufous-tipped flight-feathers; plumage retained until first complete moult, when fully adult plumage acquired. VOICE. Extremely loud, ringing "pi pi y-o", audible through 300-400 m of forest, preceded by low-pitched, much less loud "groo, groo" (air inhaled); also loud, whistling "wee-oo".
Habitat. Humid forest, including seasonally flooded forest (*várzea*); also including *campinarana*, *terra firme* and *igapó* forest on sandy soil along Amazon. Mainly below 500 m, but to 1000 m in Andean foothills and 1400 m in Venezuela. Occurs at lower altitudes than *L. lanioides* where ranges overlap (SE Brazil).
Food and Feeding. Fruit and insects; single record of *Anolis* lizard, beaten against perch and swallowed at third attempt. Temporary tendency to concentrate on one or other food source indicated by records of stomach contents consisting mostly either of fruit or of insects, not both. Items usually taken in flight sally. Occasionally accompanies mixed-species foraging flocks.
Breeding. Nest found in Sept in Brazil (near Manaus); on evidence of moult, season evidently varies from N to S of range, with extensive C area where seasonality poorly marked. Male displays at lek, maintains small territory c. 5-8 m up in tree, separated from nearest neighbour by c. 40-60 m; attracts females by loud calling while jerking head backwards; usually up to 25 males, sometimes many more, at single lek. One nest documented, very small stick structure, entirely concealed by sitting bird, 7 m above ground on side branch of small tree, supported by branch and side twig. Clutch size and incubation and fledging periods not known.
Movements. None recorded.
Status and Conservation. Not globally threatened. Locally common to uncommon, and very widespread. Tolerant of variety of forest types, including quite small patches. Occurs in numerous protected areas throughout range. Isolated population in E Brazil presumably the only one at any possible risk, as forest in that region widely destroyed and remaining habitat at greatest threat; nevertheless, this species appears not uncommon there, and it occurs in Monte Pascoal National Park and Sooretama Biological Reserve; present also near Murici (Alagoas), where humid Atlantic Forest only partially protected.
Bibliography. Bates & Parker (1998), Best *et al.* (1997), Blake (1962), Brooks *et al.* (1999), Butler (1979), Canaday & Jost (1997), Cohn-Haft *et al.* (1997), Érard (1982), Haffer (1967), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Hinojosa *et al.* (1998), Mee *et al.* (2002), Meyer de Schauensee (1982), Oniki & Willis (1982), Oren & Parker (1997), Pinto (1940), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Schubart *et al.* (1965), Sick (1993, 1997), Snow, B.K. 36. Rufous Piha

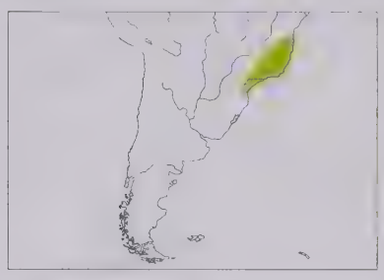
Lipaugus unirufus

French: Piauhau roux **German**: Zimtrote Piha **Spanish**: Guardabosques Rojizo

Taxonomy. *Lipaugus unirufus* P. L. Sclater, 1860, Playa Vicente, Oaxaca, Mexico.
Geographical variation in colour over most of extensive range generally slight, considered not to merit taxonomic recognition; described race *clara* (Panama) synonymized with nominate. Two subspecies recognized.
Subspecies and Distribution.
L. u. unirufus P. L. Sclater, 1860 - S Mexico (E from N Oaxaca) E to N Honduras and E Nicaragua, and S to Panama and W Colombia (E to middle Magdalena Valley).
L. u. castaneotinctus (Hartert, 1902) - extreme SW Colombia and NW Ecuador (Esmeraldas).

Descriptive notes. 23-24 cm; 69-87 g, mean 82·1 g. Plumage is cinnamon-brown overall, slightly brighter on crown, wings and tail, somewhat paler below, especially on throat; iris brown; bill dark brown or blackish, base flesh-coloured; legs dark grey to olive. Sexes alike. Immature plumage is similar to that of adult. Race *castaneotinctus* is darker, more chestnut-tinged, than nominate. VOICE. Utters a single loud, shrill and far-carrying "peer"; also makes two softer, less insistent calls, "cheer-weet", which is occasionally three-noted "whee-er-wit", and a short loud trill or a longer, very musical trill.
Habitat. Humid forest and mature secondary growth, occasionally adjacent more open areas; up to 1200 m.
Food and Feeding. Fruits, and invertebrates. Fruits include, in particular, those of palms and Lauraceae. Invertebrates mainly insects, also spiders; a small scorpion (Scorpiones) also recorded. Items usually taken in flight sally at middle levels of forest, rarely also from ground.
Breeding. Laying in Mar-Aug in Costa Rica, probably up to two broods; on evidence of moulting dates, breeding season earlier in W Colombia and Ecuador. Nest (Central America) an extremely small and slight saucer of coiled tendrils (egg easily visible from below), sited 5-11 m above ground,



usually supported between two or more thin horizontal twigs well out from trunk on side branch of small tree. Clutch 1 egg; incubation period c. 25-26 days; fledging period 28-29 days.
Movements. None recorded.
Status and Conservation. Not globally threatened. Reasonably common throughout much of its range. Occurs in Alexander Skutch Private Reserve, in Costa Rica, and Darién National Park, in Panama. Uncommon to locally common in S, where extensive destruction of lowland forest in SW Colombia and NW Ecuador may eventually threaten survival of race *castaneotinctus*; range has apparently contracted in Ecuador, where formerly extended S to S Pichincha.
Bibliography. Beletsky (1998, 1999), Best *et al.* (1997), Binford (1989), Brodkorb (1943), Butler (1979), Chapman (1917c), Cooper (1997), Cracraft (1985), Eisenmann (1955), González-García (1993), Griscom (1950), Haffer (1967, 1975), Hilty & Brown (1986), Howell & Webb (1995a), Jahn & Mena (2002b), Land (1970), Meyer de Schauensee (1982), Moermond & Denslow (1985), Monroe (1968), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Selvin & Castillo (2000), Skutch (1969, 1999), Slud (1960, 1964), Smithe (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996).

37. Cinnamon-vented Piha

Lipaugus lanioides

French: Piauhau à tête grise **German**: Graubraune Piha **Spanish**: Guardabosques Lanioide

Taxonomy. *Turdampelis lanioides* Lesson, 1844, Rio de Janeiro, Brazil.
Monotypic.
Distribution. SE Brazil, from SE Bahia, C Minas Gerais and Espírito Santo S to NE Santa Catarina.

Descriptive notes. 27-28 cm; 85-110 g. Plumage is mostly grey, crown weakly scaled, upperparts with brownish wash, brownest on wings and tail; primaries slightly, but uniquely, modified, P9 (next to outermost) distinctly long, projecting beyond otherwise curved outline of spread wing; underparts mostly pale greyish-brown with small whitish shaft streaks, cinnamon-buff undertail-coverts; iris dark brown; bill dark brown or blackish, paler base of lower mandible, inside of gape pink-yellow; legs grey. Sexes alike. Juvenile undescribed. VOICE. Generally silent; loud whistle of several notes, a typical sequence "skeeo-skeeo, skeeo-skeeo, skeeo-sheét", given at long intervals.
Habitat. Humid forest in mountainous country, from foothills to 1400 m, mainly 500-1000 m. Occurs at higher altitudes than *L. vociferans* where ranges overlap. Occasionally recorded at much lower levels in S of range.
Food and Feeding. Mainly fruits, also large insects. In observations at Intervales (São Paulo), diet estimated to be c. 86% fruits and 14% insects; fruits comprised those of 38 plant species (of 20 families), mainly *Euterpe* palms, with average width 8·3 mm (range 2·2-23 mm). Nestling fed entirely with insects for first 12-14 days, then up to 30% fruit per day. Foraging adult peers about slowly, sidling or sallying for fruits or insects on foliage or branches.
Breeding. Laying recorded in Dec-Feb; nesting season probably Sept-Mar. Nest (three found) an extremely small, thin platform of twigs, placed 7-8 m above ground on horizontal twig and side twig of small tree. Clutch 1 egg; incubation period 26 days; fledging period 25-26 days.
Movements. Possibly some altitudinal movements in S of range, where recorded near sea-level.
Status and Conservation. VULNERABLE. Rare; population small and fragmented. In extreme S of range, recent records from only one site in each of E Paraná and Santa Catarina. Most numerous in Augusto Ruschi Biological Reserve (Espírito Santo), where population estimated at a few hundreds, and reasonably common in same state at Pindobas IV; also common in Intervales State Park (São Paulo); occurs also in Monte Pascoal and Serra dos Órgãos National Parks and Serra do Brigadeiro and Rio Doce State Parks. Numbers undoubtedly greatly reduced by widespread destruction of E Brazilian coastal forests, and further threatened by human exploitation of *Euterpe* palms, a Brazilian delicacy.
Bibliography. Aleixo & Galetti (1997), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga, Jones & Scott (1987), Collar, Gonzaga, Krabbe *et al.* (1992), Cracraft (1985), Forrester (1993), Gonzaga *et al.* (1995), Guix (1995), Guix *et al.* (1992), Meyer de Schauensee (1982), Ridgely & Tudor (1994), do Rosário (1996), Schubart *et al.* (1965), Scott & Brooke (1985), Sick (1993, 1997), Simon *et al.* (1999), Souza (1999), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993), Willis & Oniki (1998).

38. Rose-collared Piha

Lipaugus streptophorus

French: Piauhau à collier **German**: Halsbandpiha **Spanish**: Guardabosques Acollarado

Taxonomy. *Lathria streptophora* Salvin and Godman, 1884, Roraima, Venezuela.
Monotypic.
Distribution. Tepuis of SE Venezuela and adjacent N Brazil and Guyana.

Descriptive notes. 22·5 cm. Distinctive piha; striking sexually dimorphic plumage unique within genus. Male is grey above, paler below, especially on belly; has full collar and undertail-coverts pinkish-magenta; iris dark brown; bill dark brown or blackish, paler base of lower mandible; legs grey. Female is slightly smaller than male, lacks pink collar, has undertail-coverts cinnamon-rufous. Juvenile undescribed. VOICE. Main call a clear, whistled "sueeet-suéééeeeeoo", rising and then falling, often given in incomplete form; another call described as loud and very sharp "skreeyr", given at long intervals, perhaps same as call described as a screeching trill (uttered repetitively by displaying male). Explosive "pow, pow" made by displaying male perhaps mechanical wing noise.
Habitat. Montane forest, regularly forest edge; 1000-1800 m.
Food and Feeding. Mainly fruits, especially of Melastomataceae, taken in flight sally or flutter; also insects.
Breeding. Female collecting nest material in Apr; moult (presumably post-breeding) begins over extended period, Dec-May. No other information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Status not well known; apparently uncommon, possibly local, but may be more numerous in some places. Occurs in Canaíma National Park, in Venezuela. Despite small range, is not thought to be at any risk; much intact forest remains on slopes of table mountains, which are difficult of access for humans.
Bibliography. Barnett *et al.* (2002), Chapman (1931), Cracraft (1985), Forrester (1993), Hilty (2003), Mayr & Phelps (1967), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Rodner *et al.* (2000), Sick (1993, 1997), Snow (1982), Snyder (1966), Stotz *et al.* (1996).

Genus *TIJUCA* Férussac, 1829

39. Black-and-gold Cotinga

Tijuca atra

French: Cotinga noir **German**: Goldflügelkotinga **Spanish**: Cotinga Negro

Taxonomy. *Tijuca atra* Férussac, 1829, Serra do Mar, Rio de Janeiro, Brazil.
Validity of genus uncertain; possibly better merged with structurally similar *Lipaugus*, as analysis of feather proteins suggested close relationship with *L. vociferans*; further study required. Monotypic.
Distribution. SE Brazil, in extreme E São Paulo, extreme S Minas Gerais and Rio de Janeiro.

Descriptive notes. 26·5-27·5 cm. General proportions like those of a thrush (Turdidae), with rather short wings rounded at tip; slightly hooked bill notched near tip, rictal bristles weakly developed. Male is black, with large golden-yellow patch on flight-feathers; iris reddish-brown; bill bright orange; legs dark brown. Female is dull olive-green, yellower on flight-feather edges and belly, bill duller and browner. Immature plumage is like female; in male, this replaced by subadult plumage in which variable number of contour feathers (especially on belly) of immature type, followed by full adult plumage. VOICE. Male call an extremely pure whistle, with short break, followed by slightly higher-pitched ending, the whole lasting c. 3 seconds, interval between calls c. 2 seconds; two or more males regularly call together from treetops, alternating calls so as to produce continuous whistling audible for considerable distance.
Habitat. Montane forest; mainly 1200-2050 m.
Food and Feeding. Mainly fruit, also insects. Few identified records, but fruits of Lauraceae apparently important, and those of *Rapanea* (Myrsinaceae) also taken. Fruits usually taken from perched position, occasionally plucked in fluttering flight; insects mostly seized from foliage in short aerial sally.
Breeding. Old record of nest found in Nov, without details; available data indicate that females begin to moult in Dec, suggesting possible breeding in Sept-Nov, similar to that of other species in same area. No other information.
Movements. Some wandering to lower altitudes in off-season indicated by Jul record in Serra do Itatiaia at c. 1150 m, c. 600 m below usual level in that area.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Atlantic Forest Mountains EBA. Locally common. Numerous in upper parts of Itatiaia and Serra dos Orgãos National Parks, and reasonably common elsewhere in suitable habitat. Although confined to very small range, montane forest in area in which it occurs has suffered comparatively little compared with adjacent lowland forest. Habitat is little disturbed, and much of it steep and difficult of access. Sometimes hunted for food.
Bibliography. Cracraft (1985), Descourtilz (1983), Forrester (1993), Hellmayr (1929), Meyer de Schauensee (1982), Parker *et al.* (1996), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Snow & Goodwin (1974), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993), Wilkinson (1996).

40. Grey-winged Cotinga

Tijuca condita

French: Cotinga à ailes grises **German**: Grauflügelkotinga **Spanish**: Cotinga Aligrís
Other common names: Orgaos/Snow's Cotinga

Taxonomy. *Tijuca condita* Snow, 1980, Serra dos Órgãos, Rio de Janeiro, Brazil.
Validity of genus uncertain; possibly better merged with the structurally similar *Lipaugus*, as an analysis of feather proteins suggested close relationship with *L. vociferans*; further study required. Monotypic.
Distribution. Serra dos Órgãos and Serra do Tinguá, c. 40-50 km NE of Rio de Janeiro, Brazil.

Descriptive notes. 24 cm. Male has dull greyish face and upper throat; olive-green above, yellower on rump, darker and browner wings and tail, outer webs of remiges silvery grey; olive-yellow below, yellower belly and underwing-coverts; iris brown; upper mandible dark grey, lower mandible yellow-olive; legs dark horn. Distinguished from similar *T. atra* female mainly by smaller size, brighter plumage coloration, silvery colour on flight-feathers. Female is smaller than male, plumage duller; very like female *T. atra* but much smaller, with smaller, more delicate bill, markedly more delicate legs and feet, also stronger

suffusion of yellow in body plumage, especially on rump, and greyer wings. Juvenile undescribed.
Voice. Male call a loud disyllabic whistle, emphasis on second syllable, "sooee-wheee", c. 1·25 seconds long; at distance only second syllable audible.
Habitat. Very humid elfin cloudforest with many bromeliads; mainly 1370-1980 m, probably at least occasionally descends lower.
Food and Feeding. Recorded as feeding on berries, including small melastomes (Melastomataceae). No further information.
Breeding. Female mist-netted in mid-Nov had well-developed brood patch. No other information available.
Movements. Probably wanders at least occasionally to levels well below high-altitude elfin forest; unique specimen, from near Teresópolis (lower slopes of Serra dos Órgãos) in Oct, almost certainly below 1370 m but altitude not recorded.

Status and Conservation. VULNERABLE. Restricted-range species: present in Atlantic Forest Mountains EBA. Original and only specimen, a female collected in 1942, originally identified as *T. atra*; not recognized as separate species until almost 40 years later. Has tiny range and presumed small population; few observations, and seems to exist in very low densities. Known to occur in only two mountain ranges: almost all records from Serra dos Órgãos, but recorded also in Serra do Tinguá. Occurs in both Serra dos Órgãos National Park and Tinguá Biological Reserve. High-altitude elfin-forest habitat not under any immediate threat, but disturbance caused by walkers, as well as fires, pose potential risks. Any significant deterioration in or loss of habitat would require upgrading of species' conservation status to that of Endangered.

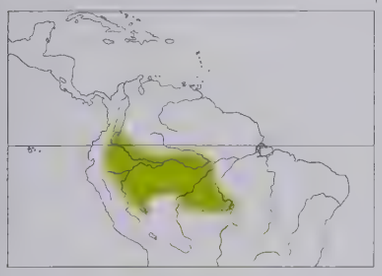
PLATE 5

inches 4

cm 10

Genus *PORPHYROLAEMA* Bonaparte, 1854



41. **Purple-throated Cotinga**

Porphyrolaema porphyrolaema

French: Cotinga à gorge mauve **German**: Purpurkehlkotinga **Spanish**: Cotinga Gorgimorado

Taxonomy. *Cotinga porphyrolaema* Deville and P. L. Sclater, 1852, Sarayacu, River Ucayali, Peru. Monotypic.

Distribution. S Colombia, E Ecuador, E Peru (S to Madre de Dios) and W Amazonian Brazil (E to lower R Negro and N Mato Grosso).

Descriptive notes. 18-18·5 cm; mean 60 g. Distinctive; wide bill with strongly arched culmen, rictal bristles weakly developed. Male is black above, including wings and tail, has white fringes on back to uppertail-coverts and on upperwing-coverts, conspicuous white band along inner wing-coverts and edges of tertials; deep purple on throat; white below, some black barring on rear flanks; iris dark brown; bill blackish; legs blackish. Female is very different, dark brown with pale buff margins above, cinnamon-buff with black barring below, deeper and more plain rufous on throat; also body feathers of looser texture than those of adult male, and tail feathers longer and more pointed at tip. Juvenile is like female, but paler and buffier; immature unrecorded. Voice. High, plaintive "preeeeeer", 1-2 seconds long, regularly repeated from treetop perch.

Habitat. Humid forest to 900 m, mostly to c. 400 m.

Food and Feeding. Mainly fruits of forest trees, including *Cecropia*. Only two records of feeding behaviour, both of birds perched and leaning down to pluck fruit. Often in pairs.

Breeding. No information. Dates of moult (presumed post-breeding) suggest breeding at almost all times of year.

Movements. None recorded.

Status and Conservation. Not globally threatened. Not well known. Apparently uncommon or rare, but widespread; as other birds that stay mainly in canopy, is almost certainly under-recorded in areas of unbroken forest. Occurs in several protected areas, e.g. Amacayacu National Park, in Colombia, Cuyabeno Reserve, in Ecuador, Rio Cristalino Forest Reserve, in Brazil, and Manu National Park and Biosphere Reserve, in Peru.

Bibliography. Best *et al.* (1997), Brooks *et al.* (1999), Butler (1979), Cracraft (1985), Gyldenstolpe (1950), Hellmayr (1929), Hilty & Brown (1986), Meyer de Schauensee (1982), Negret (2001), Parker, Donahue & Schulenberg (1994), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson (1997), Sick (1993, 1997), Stotz *et al.* (1996), Terborgh *et al.* (1984), Whittaker (1996a, 1996b), Zimmer *et al.* (1997).

Genus *COTINGA* Brisson, 1760

42. **Lovely Cotinga**

Cotinga amabilis

French: Cotinga céleste **German**: Azurkotinga **Spanish**: Cotinga Azulejo

Taxonomy. *Cotinga amabilis* Gould, 1857, Verapaz, Guatemala.

May form a superspecies with *C. ridgwayi*, *C. nattererii*, *C. maynana*, *C. cotinga* and *C. maculata*, and all sometimes treated as conspecific. Monotypic.

Distribution. SE Mexico (from S Veracruz and N Oaxaca) E to N Honduras and E Nicaragua and S to E Costa Rica.

Descriptive notes. 18-19 cm; 66-75 g. Male is mostly deep turquoise-blue, feathers with concealed black bases; wings black with very narrow blue edges, edges broader on tertials and greater wing-coverts; median and lesser coverts similar to back; primary P7 short, P8 and P9 with outer webs sinuated; tail (almost concealed by long uppertail-coverts) black; large purple patch on throat, larger one on breast and upper belly; iris dark brown; upper mandible blackish with grey base, lower mandible grey; legs dark grey. Differs from *C. ridgwayi* mainly in larger size, longer uppertail-coverts, from *C. nattererii* in less dark throat patch and absence of black eyering, from both in structure of primaries. Female is very different, dark brown with buff-white fringes above, wings and tail dusky brown, median and lesser coverts patterned like back, edges of greater coverts and tertials more cinnamon; underparts whitish with brown spotting, undertail-coverts plain. Immature is like adult female, flight-feathers with buff tips (tend to wear off); adult male plumage acquired when just over a year old (except that purple of throat tends at first to be paler). Voice. Generally silent; screaming calls by female when mobbing nest predator, and clear monosyllabic "ic, ic, ic" when alarmed by human searching for fallen chick. Flying male makes light rattling wing noise.

Habitat. Canopy of humid evergreen forest; also more open areas with scattered trees. To 1700 m.

Food and Feeding. Fruits, especially of Lauraceae, plucked in fluttering sallies; also insects and small lizards.

Breeding. Nest found in mid-May in Costa Rica, probably cup-shaped, c. 31 m up in treetop, hidden in epiphytes, contained at least 1 nestling. No other information.

Movements. None recorded. Single record from W Panama (Bocas del Toro) in 1978 possibly involved wandering individual from adjacent Costa Rica.

Status and Conservation. Not globally threatened. Rare and local in most of range; possibly uncommon in some N parts. Population much reduced by extensive deforestation throughout its range.

Bibliography. Angehr (2003), Bangs (1903), Beletsky (1999), Binford (1989), Blake, E.R. (1953), Cooper (1997), Dearborn (1907), Eisenmann (1955), Fogden (1993), González-García (1993), Haffer (1967), Hellmayr (1929), Howell & Webb (1995a), Land (1970), Lee Jones (2004), Levey & Stiles (1994), Monroe (1968), Parker (1993a), Ridgely & Gwynne (1989), Ridgway (1907), Selvin & Castillo (2000), Skutch (1969), Slud (1964), Stiles (1983, 1985), Stiles & Skutch (1989), Stotz *et al.* (1996).

43. **Turquoise Cotinga**

Cotinga ridgwayi

French: Cotinga turquoise **German**: Ridgwaykotinga **Spanish**: Cotinga Turquesa
Other common names: Ridgway's Cotinga

Taxonomy. *Cotinga ridgwayi* Ridgway, 1887, Pozo Azul, Costa Rica.

May form a superspecies with *C. amabilis*, *C. nattererii*, *C. maynana*, *C. cotinga* and *C. maculata*, and all sometimes treated as conspecific. Monotypic.

Distribution. Pacific slope of Costa Rica (S from Gulf of Nicoya) and W Panama (S to Chiriquí).

Descriptive notes. 17-18·5 cm; male 51·5-54 g, female 63·2-65·7 g. Male is mostly deep turquoise-blue, feathers with concealed black bases; wings black with very narrow blue edges, edges broader on tertials and greater wing-coverts; median and lesser coverts similar to back; primaries P9 and P10 thin and short, P9 especially so, somewhat incurved at tip, and P8 and P9 with outer webs sinuated near base; tail (partly concealed by long uppertail-coverts) black; large purple patch on throat, larger one on breast and upper belly; iris dark brown; upper mandible black with greyish base, lower mandible grey with blacker tip; legs dark grey or blackish. Differs from *C. amabilis* in somewhat smaller size, shorter uppertail-coverts (no more than two-thirds length of tail), from *C. nattererii* in bill proportions, absence of black eyering, less blackish throat patch, from both in structure of primaries. Female is markedly larger than male, dark brown with buffish-white fringes above, wings and tail dusky brown, median and lesser wing-coverts like back, edges of greater coverts and tertials more cinnamon; underparts pale buff with greyish-brown spotting, undertail coverts plain buff. Immature is like adult female, flight-feathers with buff tips (tend to wear off); male much as adult when just over a year old. Voice. Generally silent; female distress call a raucous shriek. Flying male makes soft twittering wing noise.

Habitat. Canopy of humid forest and second-growth woodland; to 1850 m, in Panama generally below 900 m.

Food and Feeding. Only fruits recorded, of a wide variety, from tree fruits and parasitic mistletoes (Loranthaceae) to berries of low-growing poke-weed (*Phytolacca*).

Breeding. Single record from Costa Rica. Nest a slight, shallow cup of coiled tendrils and long fungal strands, sited 9 m up at fork of horizontal branch of isolated tree near forest edge; 2 eggs laid in Mar. No other information.

Movements. Evidently subject to irregular wandering, perhaps related to local availability of fruit.

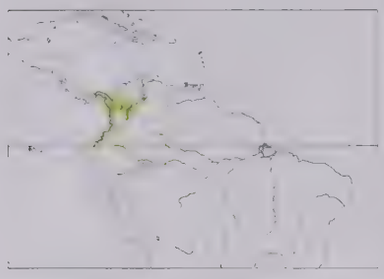
Status and Conservation. VULNERABLE. Restricted-range species: present in South Central American Pacific Slope EBA. Generally rare and local, and has very small range. Recent records from only few sites in Costa Rica, i.e. Carara Biological Reserve, the Osa Peninsula (including Corcovado National Park), and the E foothills; in Panama, found recently only in Santa Clara area (W of Volcán) and at El Chorogo. Extensive destruction of forest has severely reduced its numbers and range in Panama, and remaining habitat in Costa Rica is inadequately protected.

Bibliography. Angehr (2003), Angehr & Jordan (1998), Collar & Andrew (1988), Collar *et al.* (1994), Delgado (1985), Eisenmann (1955), Haffer (1967), Hellmayr (1929), Moermond & Denslow (1985), Ridgely & Gwynne (1989), Ridgway (1907), Skutch (1969), Slud (1964), Snow (1982), Stattersfield & Capper (2000), Stiles (1983, 1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wege & Long (1995), Wetmore (1972).

44. **Blue Cotinga**

Cotinga nattererii

French: Cotinga bleu **German**: Nördliche Prachtkotinga **Spanish**: Cotinga Azul
Other common names: Natterer's Cotinga



Taxonomy. *Ampelis Nattererii* Boissonneau, 1840, "Bogotá" [presumably from lower altitude in adjacent Magdalena Valley], Colombia.

May form a superspecies with *C. amabilis*, *C. ridgwayi*, *C. maynana*, *C. cotinga* and *C. maculata*, and all sometimes treated as conspecific. Monotypic.

Distribution. Panama (E from W Colón), Colombia (Pacific lowlands and E to middle Magdalena Valley), extreme W Venezuela (NW Táchira, Mérida) and NW Ecuador (Esmeraldas).

Descriptive notes. 18-20 cm. Male is mostly deep turquoise-blue, feathers with concealed black bases, black eyering; wings black, narrowly edged blue, edges broader on tertials and greater wing-coverts; median and lesser coverts similar to back; primary P9 with constricted inner web, P8 and P10 slightly so; tail (almost concealed by long uppertail-coverts) black; large purple-black patch on throat, larger and more purple one on breast and upper belly; iris dark brown; upper mandible black with greyish base, lower mandible grey with blacker tip; legs dark grey or blackish. Differs from *C. amabilis* and *C. ridgwayi* mainly in rather smaller bill, black eyering, blacker throat patch, structure of primaries; uppertail-covert length usually intermediate. Female is dark brown with

On following pages: 45. Plum-throated Cotinga (*Cotinga maynana*); 46. Purple-breasted Cotinga (*Cotinga cotinga*); 47. Banded Cotinga (*Cotinga maculata*); 48. Spangled Cotinga (*Cotinga cayana*).

pale scaling above, including on median and lesser wing-coverts, has greater coverts and secondaries edged cinnamon-buff; underparts cinnamon-buff with dusky brown centres, giving scaly appearance, undertail-coverts plain cinnamon-buff. Immature resembles female, flight-feathers with buff tips (tend to wear off); male like adult when just over a year old, except that often initially slightly paler. VOICE. No vocal sound by male; flying male makes whistling wing noise. Loud shrieks by female at nest.

Habitat. Canopy of humid forest and secondary woodland, mostly below 300 m, occasionally higher; to 1000 m, locally 1400 m, in Colombia.

Food and Feeding. Only fruit recorded, usually taken in brief fluttering sally. Sometimes forages in small groups of up to c. 10 individuals.

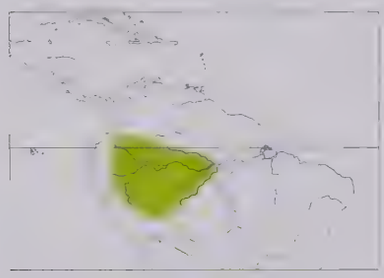
Breeding. Two records of laying in Feb in Panama. Nest, used in two successive years, 28 m above ground in sandbox tree (*Hura crepitans*), in angle formed by orchid growing from side of nearly horizontal branch; clutch presumed 2 eggs, as 2 nestlings observed. No other information.

Movements. None recorded.

Status and Conservation. Not globally threatened. Uncommon to rare throughout range. Numbers undoubtedly much reduced by extensive destruction of lowland forest, especially in Ecuador, where now very rare. Rare in Río Claro Reserve, in Colombia.

Bibliography. Best *et al.* (1997), Butler (1979), Chapman (1917c), Chapman (1929a), Cracraft (1985), Delgado (1985), Eisenmann (1955), Haffer (1967, 1975), Hellmayr (1929), Hilty (1997, 2003), Hilty & Brown (1986), Jahn & Mena (2002c), Meyer de Schauensee (1982), Moynihan (1960), Parker (1992c), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Stotz *et al.* (1996), Velásquez (1991), Wetmore (1972), Willis & Eisenmann (1979).

45. **Plum-throated Cotinga**



Cotinga maynana

French: Cotinga des Maynas **German**: Veilchenkehlkotinga **Spanish**: Cotinga Mayna

Taxonomy. [*Ampelis*] *Maynana* Linnaeus, 1766, Maynas, Peru.

May form a superspecies with *C. amabilis*, *C. ridgwayi*, *C. nattererii*, *C. cotinga* and *C. maculata*, and all sometimes treated as conspecific. Monotypic.

Distribution. C & W Amazon Basin in S Colombia, E Ecuador, E Peru, Brazil (E to lower R Negro and lower R Madeira) and N Bolivia.

Descriptive notes. 19·19·5 cm; mean 69 g. Male is turquoise-blue, some pink feather bases showing through; comparatively small deep purple patch on throat; flight-feathers and rectrices black with blue edges, closed wing appears mostly blue; primaries P7-P10 with inner webs sinuated, P8 very slender; iris yellow; bill dark grey or blackish; legs dark grey or blackish. Female is on average larger than male, has upperparts and wings greyish-brown, inconspicuously scaled buff, underparts paler greyish-brown, becoming ochraceous on belly and undertail-coverts, some feathers with darker centres giving mottled appearance, especially on breast; iris often duller and darker than male's. Immature is like female, flight-feathers with buff tips (tend to wear off); adult male plumage acquired when just over a year old, but throat colour often initially paler. VOICE. No vocal sound recorded. Male makes twittering wing noise in normal flight, much louder in display-flight.

Habitat. Canopy of humid forest, especially seasonally flooded forest (*várzea*); mostly below 700 m.

Food and Feeding. Only fruit recorded, usually taken in fluttering sally, sometimes while perched. The large, plum-like fruits of mistletoes of genus *Psittacanthus* much favoured, attracting birds from a distance. Often found together with *C. cayana*.

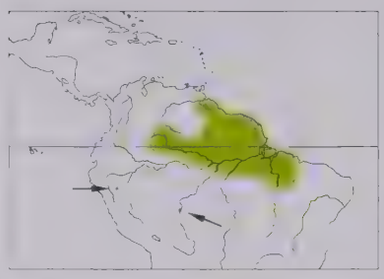
Breeding. No clear information on breeding season. Displaying male flies slightly downwards from high perch, then out over open space for c. 40 m, suddenly brakes with loud "whirr" wing noise, and returns to perch. Nothing else known.

Movements. None recorded.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common; at least locally common in upper and central Amazonian forest region. In Ecuador, severe decline in numbers recorded at Jatun Sacha (W Napo); causes unknown. Occurs in several protected areas, e.g. Amacayacu National Park, in Colombia, and Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru.

Bibliography. Allen (1995), Angehr & Aucca (1997), Best *et al.* (1997), Brooks *et al.* (1999), Butler (1979), Cohn-Haft *et al.* (1997), Cracraft (1985), Dyck (1971), Haffer (1967), Hellmayr (1929), Hilty & Brown (1986), Meyer de Schauensee (1982), Ortiz & Carrión (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson (1997), Robinson & Terborgh (1997), Sick (1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984).

46. **Purple-breasted Cotinga**



Cotinga cotinga

French: Cotinga de Daubenton **German**: Purpurlatzkotinga **Spanish**: Cotinga Pechimorado
Other common names: Blue Cotinga(!)

Taxonomy. [*Ampelis*] *Cotinga* Linnaeus, 1766, Belém, Pará, Brazil.

May form a superspecies with *C. amabilis*, *C. ridgwayi*, *C. nattererii*, *C. maynana* and *C. maculata*, and all sometimes treated as conspecific. Probably closest to last of those, which similar in plumage and in male's wingtip modification. Monotypic.

Distribution. Extreme E Colombia, S & E Venezuela, the Guianas, and N & E Amazonian Brazil (E to W Maranhão and S to extreme N Goiás; W limit uncertain); isolated records in NE Peru (San Martín) and W Brazil (Rondônia).

Descriptive notes. 18 cm; one male 53 g, one female 55 g. Bill comparatively short, curved on culmen. Male is glistening deep cobalt-blue above and on lowermost underparts, some black feather bases showing through; vinaceous purple from throat to belly; wings and tail black, blue margins on tips of median wing-coverts, lesser coverts more broadly edged blue; primary P7 short, P8 and P9 with outer webs sinuated, P9 and P10 thin and tapering at tip; iris very dark brown; bill grey, blackish at tip; legs grey. Female is smaller than male, dusky brown with conspicuous whitish scaling above, buff to whitish with contrasting dusky brown centres below, chin and undertail-coverts unspotted; very similar to female of *C. maculata*, but smaller and slightly less contrastingly scaled. Immature resembles female, flight-feathers with buff tips (tend to wear off); male acquires adult plumage when just over a year old, initially sometimes paler below. VOICE. Usually silent; rarely, a high, plaintive, repeated "preeeeeeer" heard. Flying male makes whistling wing noise.

Habitat. Canopy of humid forest; to 800 m.

Food and Feeding. Apparently only fruit. Stomachs of two specimens contained fruits of *Euterpe* palm.

Breeding. No clear information.

Movements. None recorded.

Status and Conservation. Not globally threatened. Locally uncommon to rather rare; possibly locally fairly common in the Guianas. Generally less common than sympatric and more widespread *C. cayana*. Occurs in Imataca Forest Reserve and El Dorado, in Venezuela.

Bibliography. Friedmann (1948), Gilliard (1941), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Kirwan & Hornbuckle (1997b), Meyer de Schauensee (1982), Oren & Parker (1997), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Thiollay & Jullien (1998), Whittaker (1996b), Williams (1995b).

47. **Banded Cotinga**

Cotinga maculata

French: Cotinga cordonbleu **German**: Südliche Prachtkotinga **Spanish**: Cotinga Maculado

Taxonomy. *Ampelis maculatus* Statius Muller, 1776, Rio de Janeiro, Brazil.

May form a superspecies with *C. amabilis*, *C. ridgwayi*, *C. nattererii*, *C. maynana* and *C. cotinga*, and all sometimes treated as conspecific. Probably closest to last of those, which similar in plumage and in male's wingtip modification. Monotypic.

Distribution. Littoral areas of E Brazil in SE Bahia and N Espírito Santo.

Descriptive notes. 20 cm; one male 65 g. Male is glistening cobalt-blue above and on lowermost underparts, some black feather bases showing through; vinaceous purple from throat to belly, separated by deep blue breastband; wings and tail black, median and lesser wing-coverts mostly blue; primary P7 short, P8-P10 attenuated at tip; iris dark brown; upper mandible black with greyish base, lower mandible grey with blacker tip; legs dark grey or blackish. Female is smaller than male, dusky brown with conspicuous whitish scaling above, pale greyish-buff with contrasting dusky brown centres below; very similiar to female of *C. cotinga*, but larger and slightly more contrastingly scaled. Immature is like female, flight-feathers with buff tips (tend to wear off); male acquires adult plumage when just over a year old. VOICE. No vocal sound recorded. Flying male makes sharp whirring wing noise.

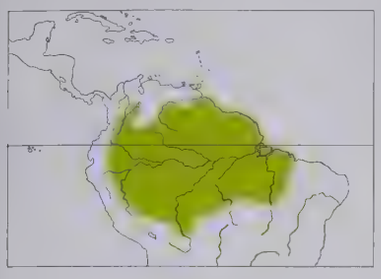
Habitat. Canopy of humid forest, to limited extent also adjacent secondary woodland; below 200 m.

Food and Feeding. Little information. Fruit; old statement that diet includes caterpillars and other insects perhaps unreliable. Fruits of *Ficus*, *Ocotea* and *Rapanea* recorded as eaten.

Breeding. Single nest found (in Oct) suggests laying in Sept or Oct, and this is supported by specimen records indicating that moult (presumed post-breeding) begins Nov-Dec. Nest was a very slight structure of small twigs, placed in horizontal fork of branch in canopy of tall tree at forest border; attended by incubating female. Report of nest inside arboreal termitarium requires corroboration.

Movements. Apparently resident; in the past some local movement reported, but none recorded in recent times.

Status and Conservation. ENDANGERED. CITES I. Restricted-range species: present in Atlantic Forest Lowlands EBA. Rare, and long considered to be decreasing. Has very small range, covering c. 780 km², and global population estimated at fewer than 1000 individuals, almost all now confined to four nominally protected reserves. Formerly occurred in Minas Gerais (last recorded in 1940) and farther S, to Rio de Janeiro (no records since 19th century). Has undoubtedly suffered serious reduction in both numbers and range following extensive destruction of lowland Atlantic Forest. Survives in Bahia in Estação Vera Cruz (Porto Seguro) and Monte Pascoal National Park, both of which are far from secure; in Espírito Santo, somewhat more effectively protected in Sooretama Biological Reserve and Linhares Natural Reserve. Possibility that it may be present in Rio Doce State Park, in Minas Gerais, requires investigation. This species was once frequently collected for the cagebird market, by which it was much prized, but is now seen with far less frequency in trade, no doubt because it has become very much rarer.



Bibliography. Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga, Jones & Scott (1987), Collar, Gonzaga, Krabbe *et al.* (1992), Cordeiro (2000), Cracraft (1985), Descourtilz (1983), Forrester (1993), Hellmayr (1929), King (1978/79), Meyer de Schauensee (1966, 1982), Ridgely & Tudor (1994), Rutgers & Norris (1977), Scott & Brooke (1985), Sick (1972, 1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993).

48. **Spangled Cotinga**

Cotinga cayana

French: Cotinga de Cayenne **German**: Türkisblaue Kotinga **Spanish**: Cotinga Celeste

Taxonomy. [*Ampelis*] *cayana* Linnaeus, 1766, Cayenne.
May be less closely related to others of genus than they are to one another. Monotypic.
Distribution. Colombia E of Andes, S & E Venezuela, the Guianas, and Amazon Basin in Ecuador, Peru, Brazil (E to Maranhão, S to Rondônia and N Goiás) and N Bolivia.

Descriptive notes. 20 cm; 56-72·5 g. Somewhat more contrastingly patterned than congeners. Male is a rather pale shining turquoise-blue, black of bases showing through on many feathers, especially on upperparts; throat purple or dark wine-red; wings, tail and scapulars black with very narrow blue edges, these broader on median and lesser wing-coverts; has primaries P9 and P10 thin and tapering, slightly recurved, P6 and P7 with barbs of outer webs forming a fringe (not interlocking), and inner secondaries very long; iris dark brown; bill blackish, greyer base of lower mandible; legs dark grey. Female is dark greyish-brown with pale buffy scaling above, similar but paler below and more obscurely scaled, with plain greyish-buff throat and buffy undertail-coverts. Immature is like adult female, flight-feathers with buff tips (tend to wear off); male much as adult when just over a year old. Voice. Male call a soft, medium-pitched "hooo", repeated 2-3 times. Flying male makes faint whistling wing noise in normal flight, louder in display-flight.

Habitat. Canopy of humid forest; to 600 m, rarely to 1300 m.
Food and Feeding. Mainly fruit, also insects. Fruits especially large mistletoe berries (Loranthaceae), usually taken in fluttering sally. Recorded as taking flying termites (Isoptera) or ants (Hymenoptera) in flycatcher fashion from treetop perch. Often found together with *C. maynana*.
Breeding. In Colombia, female brooding downy chick at end of low branch of isolated tree, chick resting on small epiphyte, apparently no trace of nest material; calculated laying date mid-Jan. Male makes display-flights in treetops; when singing, erects crown and back feathers and fans tail. No other information.
Movements. Possibly some local movements, e.g. in Venezuela.
Status and Conservation. Not globally threatened. Reasonably common; generally more abundant in E parts of range than in W, where outnumbered by *C. maynana*. Occurs in many protected areas, including e.g. Imataca Forest Reserve and El Dorado, in Venezuela; Iwokrama Forest Reserve, in Guyana; Amacayacu National Park, in Colombia; Cuyabeno Reserve and Jatun Sacha Biological Station, in Ecuador; Manu National Park and Biosphere Reserve, in Peru; and Rio Cristalino Forest Reserve, in Brazil.
Bibliography. Allen (1995), Bates & Parker (1998), Best *et al.* (1997), Blake (1950), Brooks *et al.* (1999), Butler (1979), Chaves (2001),), Cohn-Haft *et al.* (1997), Friedmann (1948), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Nicéforo (1947), Oren & Parker (1997), Ortiz & Carrión (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson (1997), Rutgers & Norris (1977), Schubart *et al.* (1965), Schürer & Bock (1995), Sick (1993, 1997), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Tostain *et al.* (1992), Willard *et al.* (1991), Zimmer & Hilty (1997), Zimmer *et al.* (1997).

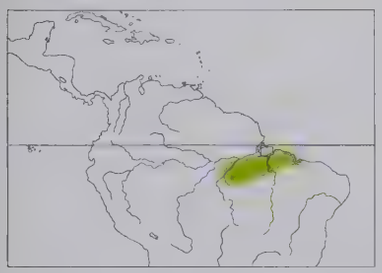
Genus *XIPHOLENA* Gloger, 1841

49. **Pompadour Cotinga**

Xipholena punicea

French: Cotinga pompadour **Spanish**: Cotinga Pompadour
German: Amazonien-Pompadourkotinga

Taxonomy. *Turdus puniceus* Pallas, 1764, South America = Surinam.
Forms a superspecies with *X. lamellipennis* and *X. atropurpurea*; only marginal range overlap with first of those in Brazil (W bank of lower R Tapajós, in W Pará). Monotypic.
Distribution. Extreme E Colombia (Arauca, Vichada S to N Vaupés), S & E Venezuela (S of R Orinoco), the Guianas, N & C Amazonian Brazil (E to Amapá and, S of Amazon, R Juruá E to W Pará and S to S Mato Grosso), NE Peru (Loreto) and extreme NE Bolivia (Serranía de Huanchaca); single record from SE Ecuador.



Descriptive notes. 19-20 cm; male 60-72 g, female 58-76 g. Distinctive; wide-based bill rather flattened dorsoventrally, slightly hooked at tip, rictal bristles absent. Male plumage has very heavy deposition of carotenoid pigments combined with structural modification of barbs, producing hard glossy surface; shining crimson-purple on head and body, paler on tertials and uppertail-coverts; secondary wing-coverts crimson-purple, greater coverts elongated and stiffened, pointed at tips, shafts white, rest of wing white, black tips on primaries; tail largely pale pink to white, more crimson-purple towards outer edges; iris pale yellow; bill dark brownish-horn; legs brownish-black, soles buff-coloured. Female is ash-grey, paler on throat and, especially, belly and undertail-coverts, blacker on wings and tail, outer edges of secondaries and greater coverts conspicuously white, those of median coverts whitish-grey, narrow whitish eyering. Juvenile resembles female, but eyes dark; immature male variable, passes through several stages, full adult plumage apparently acquired after three (presumably annual) wing moults. VOICE. Male call a loud, frog-like, rattling croak, given rarely; also rustling wing noise during display. Also loud "purp" by both sexes.
Habitat. Canopy of humid forest; to 1300 m. Found in various forest types along Amazon, including *campinarana*, *terra firme* and *igapó* forest on sandy soil.
Food and Feeding. Mainly fruit, some insects. Fruits of palms (including *Euterpe*) and *Ficus* and *Brosimum* (both Moraceae) recorded; occasionally flying ants (Hymenoptera) and termites (Isoptera), taken in sallies from treetops. Female-plumaged birds regularly, adult males rarely, accompany mixed-species foraging flocks.
Breeding. Calculated dates of onset of moult (presumably post-breeding) in all months of year, indicating no fixed breeding season. Male performs short display-flight from treetop perch. Single known nest a minute but deep open-work cup composed of a few woody tendrils, c. 18 m up in crotch of bamboo between main stem and side shoot; 1 egg. No other information.
Movements. Probably wanders, perhaps extensively, in search of fruit, but no details known.
Status and Conservation. Not globally threatened. Most numerous N of Amazon, from E Colombia E to the Guianas; S of Amazon records sparse, probably representing small local populations or wandering individuals. Occurs in several protected areas, including e.g. Imataca Forest Reserve and El Dorado, in Venezuela, Iwokrama Forest Reserve, in Guyana, and Jaú National Park, in Brazil.
Bibliography. Álvarez & Whitney (2003), Bates & Parker (1998), Beebe (1924b), Best *et al.* (1997), Blake (1950), Borgia *et al.* (1985), Cohn-Haft *et al.* (1997), Friedmann (1948), Gilliard (1941), Haffer (1997b), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sick (1993, 1997), Snow, D.W. 50. **White-tailed Cotinga**

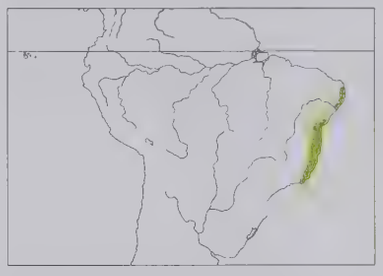
Xipholena lamellipennis

French: Cotinga à queue blanche **Spanish**: Cotinga Coliblanco
German: Weißschwanz-Pompadourkotinga

Taxonomy. *Ampelis lamellipennis* Lafresnaye, 1839, South America = Belém, Pará, Brazil.
Forms a superspecies with *X. punicea* and *X. atropurpurea*; only marginal range overlap with first of those in Brazil (W bank of lower R Tapajós, in W Pará). Described race *pallidior*, from Santarém (lower R Tapajós), is inseparable. Monotypic.
Distribution. Lower Amazonian Brazil S of Amazon, from Pará (W bank and drainage of lower R Tapajós) E to N Maranhão.



Descriptive notes. 19-20 cm. Distinctive; wide-based bill rather flattened dorsoventrally, slightly hooked at tip, rictal bristles absent. Male plumage has very heavy deposition of carotenoid pigments combined with structural modification of barbs, producing hard glossy surface; head and body shining purplish-black, tail and most of wings white; greater secondary coverts elongated and stiffened, pointed at tips, shafts white; iris pale yellow; bill dark brownish-horn; legs brownish-black, soles buff-coloured. Female is ash-grey above, blacker on wings and tail, outer edges of secondaries and greater coverts conspicuously white, those of median coverts whitish-grey, paler grey below, somewhat mottled on breast, narrow whitish eyering. Immature male resembles female, full adult plumage apparently acquired after two or three wing moults. VOICE. Loud "purp" given by both sexes.
Habitat. Canopy of humid forest; to 400 m.
Food and Feeding. Almost unknown. Probably mainly fruits; single record of *Phytolacca* fruit eaten.
Breeding. Calculated dates of onset of moult (presumably post-breeding) in nearly all months of year, indicating no fixed breeding season. Male performs short display-flight from treetop perch. Single nest, with 1 egg, found in Nov; nest not described, located 5 m up in rubber tree.
Movements. None recorded.
Status and Conservation. Not globally threatened. Poorly known. Apparently nowhere common; as its congeners, however, it is a treetop bird easily overlooked in areas of unbroken forest.
Bibliography. Forrester (1993), Haffer (1997b), Hellmayr (1929), Meyer de Schauensee (1982), Oren & Parker (1997), Pinto (1953), Ridgely & Tudor (1994), Sick (1993, 1997), Snow, D.W. (1977c), Stotz *et al.* (1996), Teixeira & de Almeida (1997), Zimmer *et al.* (1997).

51. **White-winged Cotinga**

Xipholena atropurpurea

French: Cotinga porphyrion **Spanish**: Cotinga Aliblanco
German: Weißflügel-Pompadourkotinga

Taxonomy. *Ampelis atro-purpurea* Wied, 1820, River Mucuri, Espírito Santo, Brazil.
Forms a superspecies with *X. punicea* and *X. lamellipennis*. Monotypic.
Distribution. Coastal E Brazil from Paraíba S to N Rio de Janeiro.

Descriptive notes. 19 cm; male 58-65 g, female 56-67 g. Distinctive; wide-based bill rather flattened dorsoventrally, slightly hooked at tip, rictal bristles absent. Male plumage has very heavy deposition of carotenoid pigments combined with structural modification of barbs, producing hard glossy surface; shining blackish-purple on head and body, paler on tertials and uppertail-coverts; secondary wing-coverts as body, greater coverts (not elongated) with pointed tips, rest of wing white, black tips on primaries, outer webs of primaries with thickened rami; iris pale yellow; bill dark brownish-horn; legs brownish-black, soles buff-coloured. Female is ash-grey above, blacker on wings and tail, outer edges of wing-coverts conspicuously white, underparts slightly paler grey, somewhat mottled on breast, narrow whitish eyering. Immature male resembles female, full adult plumage apparently acquired after four or five moults of remiges and rectrices. VOICE. Male call a croak, apparently similar to that of *X. punicea*; also high-pitched "chíu" notes. Loud "purp" given by both sexes. Whispering wing noise by both sexes in normal flight; quite loud wing noise by adult male in display-flight.
Habitat. Mainly dense humid forest; also, in N of range, more open forest, and in drier areas (up to more than 100 km from coast in Pernambuco and Alagoas) relatively low, semi-deciduous forest; occasionally in low-growing (to 7-8 m) scrubby forest in sandy areas near coast. Sea-level to 900 m.
Food and Feeding. Mainly fruit, also insects; occasionally flowers, including those of family Malpighiaceae, also buds and stamens of *Pachira* (Bombacaceae). Wide variety of fruits taken, with preference for those of 4-12 mm diameter; 29 species recorded, from 18 families, including Moraceae (4 species), Myrtaceae (4 species) and Lauraceae (3 species). Insect food includes caterpillars (Lepidoptera) and orthopterans (Tettigoniidae).
Breeding. Incubation recorded in Oct and egg-laying in Nov; gonad and moult data indicate season Oct-Feb. Displaying male makes upward flight of several metres from treetop perch, performs half-turn, descends steeply, with wings and tail conspicuously spread, to same perch; descent accompanied by loud wing noise. Nest a deep cup, very small for size of bird, apparently made of rootlets, perhaps with some moss, placed in fork between two vertical stems high up in tree; two recorded, one more than 15 m above ground, other 20 m up. Clutch almost certainly 1 egg; incubation and fledging periods not recorded.
Movements. None recorded.
Status and Conservation. ENDANGERED. CITES I. Restricted-range species: present in Atlantic Slope of Alagoas and Pernambuco EBA and Atlantic Forest Lowlands EBA. More or less confined to 13 protected areas (totalling 992·2 km²) along coast. Has undoubtedly suffered reduction in numbers and fragmentation of range as a result of extensive destruction of lowland forest; over 60% of Atlantic Forest habitat lost since 1980. Recent study, however, indicates greater abundance, and also wider habitat tolerance, than formerly supposed; census transects in two areas in Bahia suggested between 310 and 1187 individuals in 60·3 km²; global population estimated at 12,000-13,000 individuals. Most important areas for this species seem to be Pedra Talhada and Desengano State Parks, Una and Sooretama Biological Reserves, Monte Pascoal National Park and Linhares Natural Reserve. Continuing deforestation a threat, as also are fires, and illegal logging and other activities. Inadequate law enforcement in protected areas a major problem; several of those in which this species occurs are under threat, and the future of, especially, Monte Pascoal National Park is particularly insecure.
Bibliography. Anon. (2002b), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga, Jones & Scott (1987), Collar, Gonzaga, Krabbe *et al.* (1992), Corderio (2000), Cracraft (1985), Forrester (1993), Hellmayr (1929), King (1978/79), Laps (2000), Meyer de Schauensee (1966, 1982), Pinto & Camargo (1961), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1970, 1972, 1979a, 1993, 1997), Snow, D.W. (1977c), Stattersfield & Capper (2000), Stotz *et al.* (1996), Teixeira & de Almeida (1996a, 1996b, 1997), Teixeira & Luigi (1990), Tobias *et al.* (1993), Zimmer *et al.* (1997).

Genus *CARPODECTES* Salvin, 1865

52. **Snowy Cotinga**

Carpodectes nitidus

French: Cotinga neigeux **German**: Grauscheitelkotinga **Spanish**: Cotinga Níveo

On following pages: 53. Yellow-billed Cotinga (*Carpodectes antoniae*); 54. Black-tipped Cotinga (*Carpodectes hopkei*); 55. Black-faced Cotinga (*Conioptilon mcilhennyi*); 56. Bare-necked Fruitcrow (*Gymnoderus foetidus*).

Taxonomy. *Carpodectes nitidus* Salvin, 1865, Tucurriquí, Costa Rica.
Very closely related to *C. antoniae* and sometimes treated as conspecific, but differs in, especially, bill colour; the two replace each other geographically. Both have been considered conspecific with *C. hopkei* by some authors. Monotypic.
Distribution. Caribbean slope from NW Honduras S to extreme W Panama.

Descriptive notes. 19·5-21 cm; mean 105 g. Wide-based bill with ridged culmen, tip of upper mandible notched, distinctly uncinate; rictal bristles absent in male, slightly developed in female. Male is white, with light bluish-grey crown, very light bluish-grey wash on upperparts and part of wings; flight-feathers broad and rounded at tip; iris dark brown; bill grey, darker on culmen; legs blackish, dull brown pads of toes. Female is brownish-grey above, darker on crown, wings and tail blackish, wing-coverts and inner flight-feathers edged white and greyish-white; rather pale grey below, paler on chin, fading to white on belly, flanks and undertail-coverts; secondaries notably less broad than male's. Immature is like female; subadult male resembles adult, but flight-feathers with dark markings, tail and rump with tendency to grey wash. Voice. Male call seldom heard, consists of 2-6 rapidly repeated notes, between "chü" and "chee".
Habitat. Canopy of humid forest and adjacent tall secondary growth; to c. 750 m.
Food and Feeding. Fruits, especially of Lauraceae, mistletoes (Loranthaceae) and figs (*Ficus*); plucked either while perched or in brief flight sally.
Breeding. Data only from Costa Rica (three records). Egg laid in late Mar or early Apr, downy nestling on 21st Mar, and young fed in nest in Apr. One nest described in detail, a very small shallow cup made of small dry twigs and woody tendrils, placed 7·5 m up at junction of four branches in very exposed and leafless sandbox tree (*Hura crepitans*); two other nests 10-12 m above ground. Clutch 1 egg; incubation at least 27 days. No other information.
Movements. Evidently wanders widely, varying temporarily from common to rare in any one locality. Recent record (May 2001) from E Guatemala (Manabique Peninsula) assumed to involve wanderer from neighbouring Honduras.
Status and Conservation. Not globally threatened. Restricted-range species: present in Central American Caribbean Slope EBA. Little information on numbers, but population undoubtedly reduced by recent destruction of lowland forest.
Bibliography. Angehr (2000b, 2003), Bangs (1903), Beletsky (1998), Eisenmann (1955), Hellmayr (1929), Klebauskas & Pacheco (2000), Levey & Stiles (1994), Monroe (1968), Ridgely & Gwynne (1989), Ridgway (1907), Sánchez (2002), Slud (1960, 1964), Stiles (1983, 1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972).

53. **Yellow-billed Cotinga**

Carpodectes antoniae

French: Cotinga à bec jaune **German**: Gelbschnabelkotinga **Spanish**: Cotinga Piquiamarillo
Other common names: Antonia's Cotinga

Taxonomy. *Carpodectes antoniae* Ridgway, 1884, Pirris, south-western Costa Rica.
Very closely related to *C. nitidus* and sometimes treated as conspecific, but differs in, especially, bill colour; the two replace each other geographically. Both have been considered conspecific with *C. hopkei* by some authors. Monotypic.
Distribution. Pacific slope of Costa Rica and W Panama.

Descriptive notes. 19·5-21 cm; mean 98 g. Wide-based bill with ridged culmen, tip of upper mandible notched, distinctly uncinate; rictal bristles absent in male, slightly developed in female. Male is white, with light bluish-grey crown, very light bluish-grey wash on upperparts; flight-feathers broad and rounded at tip; iris dark brown; bill yellow, blackish culmen; legs blackish, dull brown pads of toes. Female is brownish-grey above, darker on crown, wings and tail blackish, wing-coverts and inner flight-feathers edged white and greyish-white; rather paler grey below, fading to white on lower underparts; bill duller or browner than male's, and secondaries notably less broad. Immature is like female; subadult male resembles adult, but flight-feathers with dark markings, tail and rump often washed grey. Voice. Male call "cah" or "cow" like that of a dove (Columbidae) or a trogon (Trogonidae), ending in a throaty scrape.
Habitat. Mainly coastal mangroves and adjacent woodland; occasionally isolated trees in nearby open areas. Sea-level and slightly above; also recorded, rarely, up to c. 800 m.
Food and Feeding. Only fruits recorded, including those of Lauraceae, Melastomataceae and mistletoes (Loranthaceae).
Breeding. No information. Season probably Mar-Jun. Male seen to make conspicuous display-flights between bare topmost branches of tall forest tree, and longer flights from one treetop to another.
Movements. Evidently wanders widely, as recorded well inland from preferred coastal mangrove habitat; such nomadic movements probably occur outside breeding season, but only observation of apparent courtship display was inland, at upper limit of recorded altitudinal range.
Status and Conservation. ENDANGERED. Restricted-range species: present in South Central American Pacific Slope EBA. Rare, with very small global range. Survives in a few places on Pacific coast of Costa Rica; occurs in Carara Biological Reserve and Golfito Wildlife Refuge, and recorded irregularly (seasonally) in Corcovado National Park. Very few recent records from Panama, most from close to Costa Rica border; small population discovered in 1997 in Cerro Batipa Private Reserve, and small numbers possibly still exist farther E. Population was probably never large, but has declined considerably. Preferred mangrove habitat has been extensively destroyed, and most of the adjacent areas of lowland forest and scrub have likewise been eliminated.
Bibliography. Angehr (1998, 2000a, 2003), Capper *et al.* (1998), Collar & Andrew (1988), Collar *et al.* (1992), Cooper (1997), Delgado (1985), Eisenmann (1955), Engleman (1997a, 1997b), Hellmayr (1929), Ridgely & Gwynne (1989), Ridgway (1907), Skutch (1970), Slud (1964), Stattersfield & Capper (2000), Stiles (1983, 1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972).

54. **Black-tipped Cotinga**

Carpodectes hopkei

French: Cotinga blanc **German**: Schwarzfleckenkotinga **Spanish**: Cotinga Blanco
Other common names: Hopke's/White Cotinga

Taxonomy. *Carpodectes hopkei* Berlepsch, 1897, San José, River Dagua, Colombia.
Has sometimes been treated as conspecific with *C. nitidus* and *C. antoniae*. Monotypic.
Distribution. SE Panama, and Pacific lowlands of W Colombia and NW Ecuador (S to S Pichincha).

Descriptive notes. Male 23·5-25 cm, female 22-23·5 cm. Wide-based bill with ridged culmen, tip of upper mandible notched, distinctly uncinate; rictal bristles absent in male, slightly developed in female. Male is all white (hardly any grey tinge on crown, back and tail), except for small blackish spots on tips of outer primaries and central pair of rectrices; flight-feathers broad and rounded at tip; iris orange to dark red; bill black; legs blackish, dull brown pads of toes. Differs from *C. nitidus* and *C. antoniae* in larger size, longer tail, purer white plumage, black spots on primaries and tail. Female is rather dark greyish above, wings and tail blackish, wing-coverts and inner flight-feathers edged white, paler grey below, becoming white on lower underparts, secondaries notably less broad than male's; differs from females of congeners in darker upperparts, less white at tips of wing-coverts. Immature is like female; subadult male resembles adult, but flight-feathers with dark markings, most or all of rectrices black-tipped. Voice. Not recorded.
Habitat. Humid forest, including mangroves, occasionally adjacent secondary woodland; to c. 900 m, once recorded at 1450 m.
Food and Feeding. Mainly fruit, but no details. Often recorded at universally popular *Cecropia* trees. Sometimes in small groups of 5-6 individuals.
Breeding. No information. Slow-flapping apparent display-flights by males.
Movements. Some seasonal movement suspected, but no detailed information.
Status and Conservation. Not globally threatened. Rare to locally fairly common. Occurs in Darién National Park, in Panama, and Río Palenque Science Centre, in Ecuador. Global population undoubtedly reduced by recent destruction of lowland forest, especially in NW Ecuador. Formerly considered Near-threatened; should perhaps be returned to that conservation category.
Bibliography. Angehr (2003), Best *et al.* (1997), Butler (1979), Chapman (1917c), Collar *et al.* (1994), Cracraft (1985), Delgado (1985), Eisenmann (1955), Hellmayr (1929), Hilty & Brown (1986), Jahn & Mena (2002h), Meyer de Schauensee (1945, 1982), Parker (1992a, 1992c), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Salaman (1994), Stotz *et al.* (1996), Strewe (2000b), Wetmore (1972).

Genus *CONIOPTILON* Lowery & O'Neill, 1966

55. **Black-faced Cotinga**

Conioptilon mcilhennyi

French: Cotinga à face noire **German**: Schwarzgesichtkotinga **Spanish**: Cotinga Carinegro

Taxonomy. *Conioptilon mcilhennyi* Lowery and O'Neill, 1966, Balta, River Curanja, Loreto, Peru.
Affinities uncertain; probably closest to *Carpodectes*. Monotypic.
Distribution. SE Peru (Ucayali, Cuzco, Madre de Dios) and adjacent parts of Brazil (upper R Juruá, in Acre) and Bolivia (Pando).

Descriptive notes. 23 cm; two males 89 g and 91 g, one female 81 g. Bill wide at base, slightly hooked at tip, rictal bristles well developed, scattered feathers on chin and crown with hardened shiny tips; white powder-down abundant throughout all unfeathered parts of body, absent on head, also powdery bloom on dorsal surfaces of wing and tail feathers. Has head and throat black, partly bordered by whitish crescent behind ear-coverts; upperparts dark grey, darker on wings and tail; underparts grey, fading to white lower belly and undertail-coverts; iris dark reddish-brown; bill dark greyish-brown; legs dark olive-grey. Sexes similar; female on average somewhat smaller, perhaps slightly paler on underside. Immature undescribed; one apparently subadult female had much of plumage tipped or edged with white. Voice. Song an upwardly inflected "briiing"; another call, used frequently in counter-calling between pairs, a soft, downwardly inflected "peuw".
Habitat. Humid forest, especially swampy or seasonally flooded forest along lake and river margins; in Brazil, also recorded in *terra firme* forest well away from floodplains. Occurs up to 300 m, rarely 450 m.
Food and Feeding. Mainly fruit, plucked in hovering flight; also insects, winged ants (Hymenoptera) recorded; also, perhaps exceptionally, flower parts. Regularly associates with other frugivorous species at fruiting trees, especially at large fig trees (*Ficus*).
Breeding. Two nests recorded, both in Sept in Peru; laying in late Aug or Sept in Bolivia. Both nests very small: one, made of fine plant fibres and sited c. 15 m above ground at fork of two narrow branches in *Cecropia* tree, was being built in second half of Sept; the other, described as "sufficiently small as to be invisible", was c. 35 m above ground at fork of two branches in *Ceiba* tree, and contained a single well-developed nestling, attended by both parents, end Sept. No further information.
Movements. None recorded.
Status and Conservation. Not globally threatened. Restricted-range species: present in South-east Peruvian Lowlands EBA. Not well known. Probably not uncommon. Lives in habitat where

widespread human disturbance is unlikely. Occurs in Manu National Park and Biosphere Reserve, in Peru.

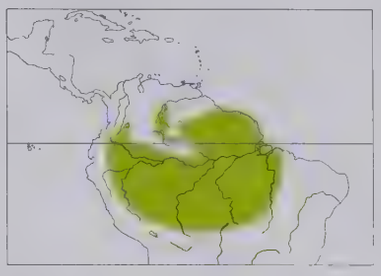
Bibliography. Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cracraft (1985), Fitzpatrick (1982), Lloyd (2000), Lowery & O'Neill (1966), Mazar Barnett & Kirwan (2001), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Robinson (1997), Robinson & Terborgh (1997), Sagot (1998), Stotz *et al.* (1996), Terborgh *et al.* (1984), Tobias (2003b), Whittaker & Oren (1999), Williams (1995b).

Genus *GYMNODERUS*

E. Geoffroy Saint-Hilaire, 1809

56. **Bare-necked Fruitcrow**

Gymnoderus foetidus



French: Cotinga à col nu **German**: Nackthalskotinga **Spanish**: Cuellopelado

Taxonomy. [*Gracula*] *foetida* Linnaeus, 1758, Surinam.

No obvious close relatives. Monotypic.

Distribution. Lowland forests of Amazonia and upper R Orinoco drainage, from SE Colombia (also extending N along base of Andes to W Meta), S Venezuela (Amazonas) and the Guianas S to E Ecuador, E Peru, Brazil (E to R Tocantins drainage and S to S Mato Grosso, including upper R Paraguai drainage) and C Bolivia; in N, apparently absent from much of R Negro drainage.

Descriptive notes. Male 34-38 cm, 331-359 g; female 30-34 cm, 1 bird 220 g. Bill smaller, less stout and more flattened dorsoventrally than in other fruitcrows, legs and feet strong; plumage of feathered parts of head dense, short and velvety, large powder-down patches on flanks. Male is black, with most of wing silvery grey; parts of head side and most of neck unfeathered, with blue or bluish-white skin extended into elaborate folds; iris variable, greyish-cream to grey or dark crimson; bill grey, black tip; legs leaden grey. Female is smaller than male, almost plain slaty grey, some pale scaling; folds on neck skin less developed. Juvenile predominantly white; immature progresses through succession of stages with whitish feather edges and, in male, dusky speckling on pale wing feathers; full adult plumage acquired after third wing moult. Voice. A deep bellowing "oooooooo" like a fog-horn, reminiscent of call of *Cephalopterus ornatus*.

Habitat. Mainly forested banks of rivers and lakes, and seasonally flooded forest; to 500 m.

Food and Feeding. Mainly fruit, including *Oenocarpus*, *Cecropia* and *Euterpe*, as well as arboreal melastome (perhaps *Miconia*). Also, to a lesser extent, insects, including large ones, e.g. mantids (Mantidae) and grasshoppers (of family Locustidae); also flying ants (Hymenoptera) or termites (Isoptera), taken by sallying high above treetops. Fruit taken while perched. Unlike other cotingids, runs actively along tree branches when foraging.

Breeding. Laying probably in Sept-Feb at S end of range, on basis of records of moult (presumably post-breeding) becoming progressively later towards N. Three nests found, one described in detail, a very small, shallow cup, of lichens and fine tendrils, the latter coated with white fungus; placed 6-10 m above ground on thick horizontal tree branch. Clutch almost certainly 1 egg.

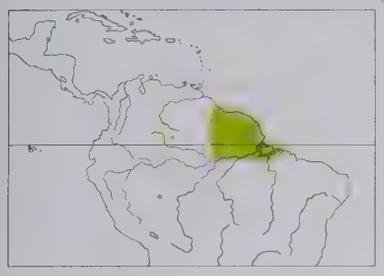
Movements. Regularly moves in high-flying flocks, conspicuous when crossing wide rivers. Uncertain whether these represent local movements or perhaps seasonal migratory movements.

Status and Conservation. Not globally threatened. Fairly common along banks of major rivers of Amazonia, forming flocks of 20 or more; less numerous in Guianan region. Occurs in several protected areas, e.g. Anavilhanas Ecological Station and Rio Cristalino Forest Reserve, in Brazil, and Tambopata-Candamo Reserved Zone and Manu National Park and Biosphere Reserve, in Peru.

Bibliography. Acheson & Davis (2001), Allen (1995), Bangs & Penard (1918), Bates & Parker (1998), Béraut (1970), Best *et al.* (1997), Blake (1962), Brooks *et al.* (1999), Davis (1993), Dubs (1992), Friedmann (1948), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Lane (2003), Meyer de Schauensee (1982), Oren & Parker (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson (1997), Schubart *et al.* (1965), Sick (1993, 1997), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Tostain *et al.* (1992), Traylor (1958), Whittaker (1996a), Zimmer & Hilty (1997), Zimmer *et al.* (1997).

PLATE 7

inches 6
cm 15



Genus *HAEMATODERUS* Bonaparte, 1854

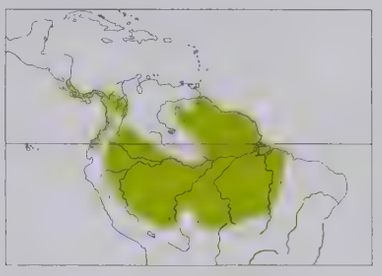
57. **Crimson Fruitcrow**

Haematoderus militaris

French: Coracine rouge **German**: Karminkotinga **Spanish**: Pájaro-militar

Taxonomy. *Coracias ? Militaris* Shaw, 1792, Cayenne.
Relationships uncertain. Monotypic.
Distribution. Extreme S Venezuela (Cerro de la Neblina), the Guianas and N & SW Brazil (E from E Roraima and Manaus area, and from lower R Tocantins E to Belém area of NE Pará; also Rondônia).

Descriptive notes. 33-35 cm. Bill strong, hooked at tip, wide basally, rictal bristles well developed, legs relatively short, feet small. Male has feathers of crown, upper back and breast highly modified, narrow and much elongated; shining crimson on head and body, breast darker crimson (feathers up to at least 105 mm long, very glossy towards tips); wings and tail dusky brown; iris dark brown; upper mandible dark reddish, lower mandible pale reddish-brown, darker along sides; legs blackish. Female is rosy crimson on head and underparts, rest of plumage dusky brown. Immature is similar to female. Voice. Male call a short, low-pitched "bock".
Habitat. Humid forest; to 200 m.
Food and Feeding. Large insects; also takes some fruit. Insects recorded as eaten include beetles (Coleoptera), cicadas (Cicadidae) and large orthopterans; taken either in foliage of forest canopy or in sallies from treetops. Fruit-eating long suspected but only recently registered: male observed to eat fruits of *Cecropia sciadophylla* in Surinam. Occasionally in small groups of 3-4 individuals.
Breeding. Nest-building recorded in Brazil (Manaus area) in Sept. Male flight-display with shallow beats to c. 30 m above forest, slow descent with wings raised and tail spread, final spiralling flight into trees. Nest apparently very small, in slight hollow at fork of horizontal branch in centre of c. 20-m high tree. No other information.
Movements. Seasonal movements suspected, but no details.
Status and Conservation. Not globally threatened. Status not well known. Seems to be generally rare, local concentrations perhaps occurring in some areas at times; not reported in recent years from Belém area of Brazil. Was for long known only from the Guianas, and a few localities in lower Amazonian Brazil; range recently greatly extended by records from extreme S Venezuela and SW part of Amazonia (Rondônia); these records, far to W of previously known range, perhaps suggest shift of "centre of gravity" of population.
Bibliography. Bierregaard *et al.* (1987), Cohn-Haft *et al.* (1997), Cracraft (1985), Forrester (1993), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1929), Mazar Barnett, Kirwan & Tobias (1998b), Meyer de Schauensee (1982), Novaes (1978a), Ottema (2002), Ridgely & Tudor (1994), Sick (1993, 1997), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Whittaker (1993).



Genus *QUERULA* Vieillot, 1816

58. **Purple-throated Fruitcrow**

Querula purpurata

French: Coracine noire **German**: Purpurbrustkotinga **Spanish**: Cotinga Quérula
Other common names: Red-breasted/Scutated Fruitcrow

Taxonomy. *Muscicapa purpurata* Statius Muller, 1776, Cayenne.
Relationships uncertain. Size (as indicated by both wing lengths and weights) varies geographically, birds from Andean foothills of Peru being considerably larger, and those from Central America somewhat larger, than birds from the Guianas; differences, however, considered not sufficient for naming of any geographical races. Monotypic.
Distribution. Caribbean side of extreme S Nicaragua, Costa Rica and W Panama and, E from Canal Zone, on both sides S to N & W Colombia (from Gulf of Urabá E to middle Magdalena Valley, and W of Andes) and NW Ecuador; also Amazonia from E Colombia (S from Meta and Vaupés), S & E Venezuela (S of R Orinoco) and the Guianas S to SE Peru, C Brazil (S to middle reaches of S tributaries) and N Bolivia; in N, apparently absent from most of R Negro drainage.
Descriptive notes. Male 28-30 cm, female 25-28 cm; male 105-122 g and female 93-101 g (Central America), male 91-115 g and female 87-104 g (the Guianas), male 112-133 g and female 100-114 g (Peru). Bill strong, broad-based, somewhat flattened dorsoventrally, hooked at tip, rictal bristles well developed; wings long for body size, with relatively long secondaries. Male is black, with large, shiny dark purple-red or crimson throat patch (throat feathers highly modified, barbs flattened and lacking barbules); iris brown to dark brown; bill grey, blacker tip of upper mandible; legs slaty black. Female is entirely black. Immature is similar to female; crimson throat feathers of adult male appear gradually, not closely linked to wing moult. Voice. Mellow disyllabic "oo-waa", typically repeated at short intervals; also variety of harsher notes, including loud harsh "wak-wak-wak-wak-wak" in alarm.
Habitat. Humid forest and mature secondary woodland; mostly below 700 m.
Food and Feeding. Fruit and insects. Nestling diet includes cicadas (Cicadidae), katydids (Tettigoniidae), mantids (Mantidae), moths (Lepidoptera) and unidentified larvae, little fruit. Food items usually plucked or seized from vegetation in swooping flight; fruits borne on strong stalks that afford a foothold may be taken from perched position. Searches for insects in typical cotingid fashion, by perching quietly and scanning surrounding vegetation. Forages in small groups.

Breeding. Laying probably in second half of year (wet season) in Panama; in the Guianas recorded in Feb and Apr, but moult records indicate much more extended breeding in first half of year. Lives in small groups of 3-8 individuals, all of which jointly attend single nest, and take part in defence of it. Nest a loose cup of twigs, lined with very fine terminal twigs (of understorey *Eugenia* tree in the two cases recorded), 11-23 m up in tree fork. Clutch 1 egg (records of 2 somewhat doubtful); incubation 25 days; nestling often fed by several of group-members, entirely with insects until 12 days old, after which small proportion of fruit included; fledging period 32-33 days.
Movements. None recorded. In only detailed study, apparently stable groups of individuals, perhaps family parties, ranged over areas of forested valley 250-350 m in extent.
Status and Conservation. Not globally threatened. Quite common in some areas. Occurs in a number of protected areas, including e.g. Si-a-Paz Reserve, in Nicaragua; Los Katíos National Park, in Colombia; Imataca Forest Reserve and El Dorado, in Venezuela; and Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru. Wide geographical range and toleration of different forest types, including secondary growth, should ensure future survival.
Bibliography. Genus *PYRODERUS* G. R. Gray, 1840

59. **Red-ruffed Fruitcrow**

Pyroderus scutatus

French: Coracine ignite **German**: Rotkehlkotinga **Spanish**: Yacutoro

Taxonomy. *Coracias scutata* Shaw, 1792, Nova Friburgo, Rio de Janeiro, Brazil.
Genus probably closest to *Cephalopterus*. Five subspecies recognized.
Subspecies and Distribution.
P. s. occidentalis Chapman, 1914 - W Andes and W slope of C Andes of Colombia, and W slope in NW Ecuador.
P. s. granadensis (Lafresnaye, 1846) - Sierra de Perijá (on Colombia-Venezuela border), N & W Venezuela (Andes, and coastal mountains E to Distrito Federal) and E Andes and E slope of C Andes of Colombia.
P. s. masoni Ridgway, 1886 - Andes of N & C Peru.
P. s. orenocensis (Lafresnaye, 1846) - E Venezuela (NE Bolívar) and adjacent N Guyana.
P. s. scutatus (Shaw, 1792) - SE Brazil (Bahia and S Goiás S to Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).

Descriptive notes. Male 43-46 cm, two birds (*scutatus*) 413 g and 419 g; female 36-39 cm, two birds (*scutatus*) 350 g and 390 g, two (*granadensis*) 300 g and 375 g. Bill strong and corvid-like, rictal bristles wiry and recurved; feathers of throat-ruff with distal ends of barbs conspicuously flattened, tips tending to be crimped or crinkled. Male nominate race is glossy black, except throat to upper breast orange with red feather tips, some warm brown spots on breast; iris blue to dark brown; bill light grey-blue to blackish; legs slaty grey to black, dull yellow-green soles. Female differs from male in smaller size, brown or grey-brown eyes, dark greyish or blackish (darkest above) bill. Immature is similar to adult, but red feathers of ruff less bright and glossy. Races vary mainly in plumage colour: *granadensis* resembles nominate, but somewhat more brown spotting on breast; *orenocensis* is duller and less glossy above, frontal feathers stiff, tending to produce median crest, underparts below breast entirely brown; *masoni* is similarly dull above, ruff deepest in colour with fringes approaching crimson-red; *occidentalis* has fringes of ruff least bright, lower underparts brown. Voice. Male advertising call a double boom consisting of two brief, but intense, hollow-sounding pulses of sound.
Habitat. Forest and forest borders, mainly humid and montane forest; lowland and locally drier forest in E Venezuela and Guyana; locally in introduced ash (*Fraxinus*) woodland adjacent to native forest in Colombia. Nominate race to 1050 m, *orenocensis* to 900 m, other races 650-2700 m.
Food and Feeding. Fruit, and large insects. Many kinds of fruit recorded, from large ones (e.g. palms, nutmegs) to small ones (*Cecropia*, *Dendropanax*). Adults eat mainly fruit; diet of younger nestlings mainly insects, both adult and larval. Fruit taken either in short aerial sallies or while perched.
Breeding. Laying in Mar-Jul, peak Apr-May, in C Andes of Colombia. Lek display rarely seen, small groups of males gather close together on perches up to c. 6 m above ground, display by

On following pages: 60. Bare-necked Umbrellabird (*Cephalopterus glabricollis*); 61. Amazonian Umbrellabird (*Cephalopterus ornatus*); 62. Long-wattled Umbrellabird (*Cephalopterus penduliger*); 63. Capuchinbird (*Perissocephalus tricolor*).

leaning forward while calling, throat feathers extended and hanging loosely, then perch erect and flare bib laterally. Reliable information otherwise only from Colombia (C Andes). Nest an open, shallow cup (allowing light to pass through), base mainly of twigs, cup exclusively of stripped fronds of the fern *Nephrolepis* (Davalliaceae), sited 5-8 m up on slender tree branch. Clutch 1 egg; incubation period not recorded; nestling fed mainly with insects until 10 days old, increasing proportion of fruit thereafter, fledging period 30-35 days.
Movements. Mostly resident. Tendency for individuals of Brazilian population (nominate) to appear briefly in areas unsuitable for residence (interior of São Paulo city; one found dead in Sorocaba city) indicates movements other than merely local, but nature of these not understood.
Status and Conservation. Not globally threatened. Uncommon to rare, and generally local. Populations in some areas reduced by deforestation. Occurs in many protected areas, including e.g. Sierra Nevada National Park, in Venezuela, Ucumarí Regional Park, in Colombia, Serra da Canastra National Park, Rio Doce State Park and Augusto Ruschi Biological Reserve, in Brazil, Ybicuí National Park (and at least four other reserves), in Paraguay, and Iguazú National Park, in Argentina. This species' ability to adapt to introduced *Fraxinus* woodland in Colombia (for both lek displays and breeding) indicates encouraging ecological flexibility, apparently unequalled by other large cotingas. Hunted for food in some areas.
Bibliography. Andrade (1996), Best *et al.* (1997), Butler (1979), Canevari *et al.* (1991), Chapman (1914), Chebez (1994), Chebez *et al.* (1999), Collar *et al.* (1987), Cracraft (1985), Ferreira de Vasconcelos & Lamas (2000), Fjeldså & Krabbe (1990), Fraga & Narosky (1985), Guerrero (2002a), Guix (1995), Hayes (1995), Hellmayr (1929), Hilty (1985, 2003), Hilty & Brown (1986), Lowen, Bartrina *et al.* (1996), Lowen, Clay *et al.* (1995), Meyer de Schauensee (1982), Negret (2001), Ortiz & Carrión (1991), de la Peña (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), do Rosário (1996), Saibene *et al.* (1996), Schubart *et al.* (1965), Serrano (1994), Sick (1993, 1997), Stotz *et al.* (1996), Zimmer (1936a).

Genus *CEPHALOPTERUS*

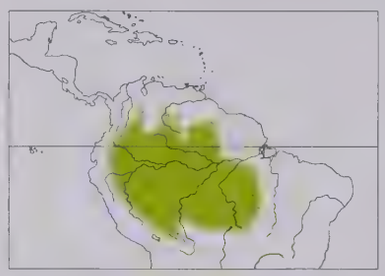
E. Geoffroy Saint-Hilaire, 1809

60. Bare-necked Umbrellabird

Cephalopterus glabricollis

French: Coracine ombrelle **German**: Nacktkehl-Schirmvogel **Spanish**: Paragüero Cuellicalvo

Taxonomy. *Cephalopterus glabricollis* Gould, 1851, Chiriquí, 8000 feet [c. 2440 m], Panama.
May form a superspecies with *C. ornatus* and *C. penduliger*; all three suggested by some as being possibly conspecific, but this considered unlikely. Monotypic.
Distribution. Mountains and surrounding foothills and lowlands of Costa Rica (E from Cordillera Guanacaste) and Panama (E to Veraguas).



Descriptive notes. Male 41 cm, 450 g; female 36 cm, 320 g. Highly distinctive, with large crest; bill large, corvid-like. Male is black; umbrella-like crest, feathers outwardly curling and terminating in brush of hair-like barbs, may be lowered so as to cover almost whole of bill or held straight up (laid back in flight); has large patch of bare, inflatatable scarlet skin covering throat, side of neck and upper breast, with thin central tassle tipped with elongated feathers; underwing mainly grey, with a little white near bend of wing; iris dark brown; upper mandible black, lower mandible plumbeous; legs plumbeous to black. Female is smaller than male, duller slaty black below, crest much reduced, appearing flat; small bare patch on side of neck. Juvenile resembles female, but greyer, crest shorter, smaller area of bare skin on neck; immature plumage not well known, but at least one subadult stage before male acquires full adult plumage. Voice. Male advertising call two resounding booms in quick succession, with accompanying dry hacking sounds; also, repeated throaty "oooaaahh" calls during interactions.
Habitat. Primary forest; 750-2100 m in breeding season, lowlands to 500 m in rest of year.
Food and Feeding. Mainly fruit, supplemented by lizards, frogs and large insects. Plant families recorded in diet include Arecaceae, Flacourtiaceae, Lauraceae, Cecropiaceae, Marcgraviaceae, Passifloraceae, Piperaceae. Food items plucked from vegetation during sallies or gleaned during hops along branches; larger items of animal food beaten against perch before swallowing.
Breeding. Laying recorded in Apr in Costa Rica; probable season, indicated by male display, Mar-May or Jun. Male displays from subcanopy perch, in loose group with other males; leans forward, bare red-skinned wattle conspicuously inflated, and calls. One nest found, in Costa Rica, a substantial cup, bulkier than nests of other large cotingids, of twigs, leaves and moss, c. 5 m up in fork of relatively isolated small tree; 1 egg; incubation at least 24 days.
Movements. Regular seasonal migration in Costa Rica, spending much of year in lowlands and foothills, females mainly below 200 m, males at 100-500 m, and moving up into mountains in breeding season; present Mar-Aug at 750-1300 m in Monteverde Forest Reserve. Probably similar movements in Panama.
Status and Conservation. VULNERABLE. Restricted-range species: present in Central American Caribbean Slope EBA and Costa Rica and Panama Highlands EBA. Uncommon to rare, and local throughout range. Global population probably small; fragmented and believed to be declining. Numbers reduced by deforestation; even in protected and intact cloudforest in Costa Rica, some display sites used in 1985-1988 no longer occupied in mid-1990s. Whereas sufficient protected highland forests remain for breeding, e.g. La Amistad International Park and Monteverde Forest Reserve, in Costa Rica, much lowland forest in non-breeding areas already lost and surviving tracts severely threatened; in N Costa Rica, for example, 35% of remaining lowland forest was removed between 1986 and 1992, and the little habitat still left is under severe threat. Important non-breeding population in Sansán-Pondsock Wetlands Ramsar Site, in Panama, but even this legally protected site is threatened by clearance for agriculture. Preservation of forest corridors linking montane breeding areas with lowland wintering areas essential for this species' long-term survival.
Bibliography. Álvarez-Cordero *et al.* (1994), Angehr (2003), Angehr & Jordan (1998), Blake (1958), Chaves *et al.* (2003), Collar & Andrew (1988), Collar *et al.* (1992), Crenshaw (2002), Delgado (1985), Eisenmann (1955), Fogden (1993), Fogden & Fogden (1997), Hellmayr (1929), Levey & Stiles (1994), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Slud (1960, 1964), Stattersfield & Capper (2000), Stiles (1983, 1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wege (1993), Wetmore (1972).

61. Amazonian Umbrellabird

Cephalopterus ornatus

French: Coracine ornée **German**: Kurzlappen-Schirmvogel **Spanish**: Paragüero Ornado
Other common names: Umbrellabird, Ornate Umbrellabird

Taxonomy. *Cephalopterus ornatus* E. Geoffroy Saint-Hilaire, 1809, Barcelos, Rio Negro, Brazil.
May form a superspecies with *C. glabricollis* and *C. penduliger*; all three suggested by some as being possibly conspecific, but this considered unlikely. Monotypic.
Distribution. Almost entire Amazon Basin, from Andean foothills in Colombia, Ecuador, Peru and Bolivia, E to S Venezuela (drainage of upper and middle R Orinoco), locally SW Guyana, and Brazil (E to R Negro and R Xingu drainages, S to S Mato Grosso, just extending to headwaters of R Paraguai).

Descriptive notes. Male 48-51 cm, probably c. 500 g; female 41-43 cm, 1 bird 380 g. The largest Neotropical passerine. Highly distinctive, with huge crest; bill large, corvid-like. Male is black with bluish gloss, duller black on abdomen; umbrella-like crest, feathers outwardly curling and terminating in brush of hair-like barbs, shafts white (conspicuous when crest upstanding), may be lowered so as to cover almost whole of bill (laid back in flight); densely feathered wattle, up to 15 cm long, hanging from lower throat, usually held close to body; iris very pale blue-grey or pearly grey, almost white; upper mandible black, lower mandible plumbeous; legs plumbeous to black. Female is much smaller than male, crest and wattle much reduced, crest feathers without white shafts. Immature not well known; at least one subadult stage before male acquires full adult plumage. Voice. Male advertising call a deep, melodious, far-carrying boom. Variety of deep but not loud ventriloquial notes, churring or growling, by both sexes; female also a succession of disyllabic calls, e.g. "goh-ahh, go-uh", second syllable often prolonged for several seconds.
Habitat. Two distinct habitats. In Amazonia and R Orinoco region, forest along riverbanks and on river islands, and adjacent seasonally flooded forest (*várzea*), mainly below 300 m; humid forest, mainly at 900-1300 m, along base of Andes.
Food and Feeding. Fruits and large insects; occasionally lizards (*Anolis* recorded). Fruits include those of palms, *Byrsonima* (Malpighiaceae) and *Cecropia*. Insects comprise especially orthopterans and beetles (Coleoptera). Animal prey snatched from foliage and branches of trees, usually in flight; beaten against perch before swallowing.
Breeding. Laying recorded in Jul in Brazil (Mato Grosso); nest-building in Oct in SE Peru. Male displays from tree perch 10-25 m above ground, in loose group with up to 4-5 other males; leans forward to call, with crest spread, wattle expanded. Nest a very open structure of twigs, so thin that egg visible from below; two recorded, both in crown of small trees, 8 m and 12 m above ground. Clutch 1 egg; incubation and fledging periods not documented.
Movements. None recorded. Significance of single old record from mouth of Amazon (Mexiana I), well outside current range, uncertain.
Status and Conservation. Not globally threatened. CITES III. Scarce or rare in much of range; locally uncommon to fairly common. Numbers reduced, and often quite local in occurrence; in most areas, this presumably a result mainly of human persecution and exploitation for food, as riverine habitat has been little modified. Destruction of forest in Andean foothills has led to declines in W of range. Occurs in several protected areas, e.g. Amacayacu National Park, in Colombia, Podocarpus National Park, in Ecuador, Anavilhanas Ecological Station and Rio Cristalino Forest Reserve, in Brazil, and Noel Kempff Mercado National Park, in Bolivia.
Bibliography. Bates & Parker (1998), Best *et al.* (1997), Blake (1962), Bloch *et al.* (1991), Briones (1991), Butler (1979), Chapman (1921), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Hinojosa *et al.* (1998), Meyer de Schauensee (1982), Ortiz & Carrión (1991), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rutger & Norris (1977), Schubart *et al.* (1965), Servat & Pearson (1991), Sick (1954, 1955, 1993, 1997), Snyder (1966), Stotz *et al.* (1996), Traylor (1958), Zimmer & Hilty (1997), Zimmer *et al.* (1997).

62. Long-wattled Umbrellabird

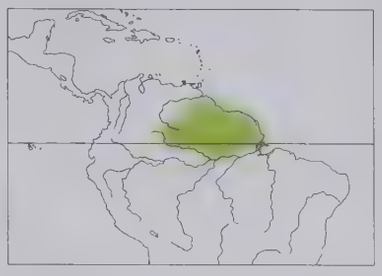
Cephalopterus penduliger

French: Coracine casquée **German**: Langlappen-Schirmvogel **Spanish**: Paragüero Corbatudo

Taxonomy. *Cephalopterus penduliger* P. L. Sclater, 1859, Pallatanga, Chimborazo, Ecuador
May form a superspecies with *C. glabricollis* and *C. ornatus*; all three suggested by some as being possibly conspecific, but this considered unlikely. Monotypic.
Distribution. Pacific slope of Andes in SW Colombia (S from Valle) and W Ecuador (S to El Oro).

Descriptive notes. Male 41 cm, female 36 cm; 1 male 338 g. Highly distinctive, with large crest; bill large, corvid-like. Male is black with bluish gloss, duller black on abdomen; umbrella-like crest, feathers outwardly curling and terminating in brush of hair-like barbs, may be lowered so as to cover almost whole of bill or held straight up (laid back in flight); has wattle up to 35 cm in length, densely feathered on both sides and flattened dorsoventrally, hanging from lower throat (retracted and held close to body in flight); underwing extensively white; iris dark brown; upper mandible black, lower mandible slate-grey to rather pale bluish; legs plumbeous to black. Female is smaller than male, wattle small or almost absent. Immature little known; at least one subadult stage before male acquires full adult plumage. Voice. Male advertising call a loud "boooh", audible for c. 400 m, given at long intervals (19-63 seconds); also low grunting calls. Female call "aaugh", perhaps in alarm.

Habitat. Humid forest, also secondary growth and traditional farmland; 80-1800 m.
Food and Feeding. Fruits of species of palm (Arecaceae), nutmeg (Myristicaceae) and laurel (Lauraceae); also occasionally insects. Nestling in only nest recorded fed mainly with small vertebrates (lizards, frog, a small snake), also large insects, and perhaps fruit. Fruits mostly taken from perched position, but those of spiny palms (*Bactris*) plucked during hovering.
Breeding. Only one certain breeding record, laying in Jun in NW Ecuador. Male displays from tree branch at traditional "exploded" lek, with up to 8-10 other males; leans forward, greatly expands wattle, and calls. Single known nest a bulky cup of dry sticks c. 50 cm long, lined with thinner twigs, epiphyte roots, tree-fern twigs and mosses, 5 m above ground in crotch at top of tree-fern; contained 1 egg.
Movements. Resident. Recorded in the past as occasionally wandering down from main high-altitude forest habitat into adjacent lowlands, but recent discoveries of resident populations in low Andean foothills and lower mountains W of Andean main range suggest that species is mainly sedentary.
Status and Conservation. VULNERABLE. CITES III. Restricted-range species: present in Chocó EBA. Rare and local in all parts of range. Global population estimated at 2500-10,000 individuals. Has apparently suffered long-term and continuing decline as a result of forest destruction combined with direct human persecution, especially hunting for food. Occurs in several protected areas, but range is increasingly fragmented. In Colombia, records concentrated in Valle de Cauca and S Nariño, including Farallones de Cali National Park (Valle), but apparently no recent records from Munchique National Park (Cauca); in Ecuador, mostly in E Esmeraldas, Pichincha and adjacent parts of Imbabura. Recent discovery in Esmeraldas of apparently healthy resident population in Jatun Sacha Bilsa Biological Reserve, in lower mountains (400-700 m) W of main Andean range, raises hopes for species' long-term survival.
Bibliography. Allen (1998), Berg (2000), Best *et al.* (1997), Bloch *et al.* (1991), Butler (1979), Clay *et al.* (1995), Collar & Andrew (1988), Collar *et al.* (1994), Cracraft (1985), Hellmayr (1929), Hilty (1985, 1997), Hilty & Brown (1986), Hornbuckle *et al.* (1997), Jahn & Mena (2002a), Jahn *et al.* (1999), Karubian *et al.* (2003), King (1978/79), Low (1995), Meyer de Schauensee (1966, 1982), Negret (2001), Parker (1992a, 1992b, 1992c), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stattersfield & Capper (2000), Stotz *et al.* (1996), Strewe (2000b), Strewe & Renjifo (2002), Wege & Long (1995).



Genus *PERISSOCEPHALUS* Oberholser, 1899

63. **Capuchinbird**

Perissocephalus tricolor

French: Coracine chauve **German**: Kapuzinerkotinga **Spanish**: Pájaro-capuchino
Other common names: Calfbird

Taxonomy. *Corvus tricolor* Statius Muller, 1776, Cayenne.
Probably closest to *Cephalopterus*; possibly related also to *Pyroderus*. Monotypic.
Distribution. Extreme E Colombia (E Vaupés), S & E Venezuela (S Amazonas, E Bolívar), the Guianas and N Brazil N of Amazon (from upper R Negro and Manaus area E to Amapá).
Descriptive notes. 34·5-35·5 cm; male 320-402 g, female 267-367 g. Very odd-looking cotingid, with "cowled" head; bill long and strong, hooked at tip, legs and feet strong, claws strongly hooked.

Has crown and face bare except for sparse hair-like feathers, skin blue-grey, more greenish-blue below bill; back of head ochraceous brown, feathers dense and upstanding, forming "cowl"; upperparts ochraceous brown, dark brown on uppertail-coverts and upperwing-coverts, flight-feathers and tail nearly black; underparts as back but more rufescent, crissum orange-rufous, undertail-coverts curled, underwing-coverts white; iris dark brown; upper mandible dark grey, paler and bluer grey base, lower mandible mainly bluish-grey; legs plumbeous grey. Sexes alike, female somewhat smaller than male. Juvenile resembles adult, but has sparse downy (not bristly) feathers on bare skin of head. Voice. Male call is a loud, mooing "grr-aaa-oooo". Female a rasping "waaaaaa" as alarm (possibly also made sometimes by males); quiet "wark" as contact call.
Habitat. Humid forest; mostly occurs below 600 m, but in Venezuelan mountains present up to 1400 m.
Food and Feeding. Mainly fruits, also large insects; single record of bat (Chiroptera) seized from among foliage. Fruits mostly from trees in forest understorey or lower canopy; those of at least 8 plant families recorded in diet, with Lauraceae, Burseraceae and Arecaceae (*Euterpe*) of particular importance. Insects include especially orthopterans. Hanging fruits plucked in flight, those that are accessible taken while perched. Insect-searching technique consists of moving with short flights through understorey, perching motionless while scanning surrounding vegetation, and flying to snatch prey from foliage or branch.
Breeding. Laying in Feb-Apr in Guyana, Nov-Mar in Surinam and Jul and Oct in French Guiana; song and display at least Dec-Jul, strongest in Jan-Mar, in Venezuela. Male displays on subcanopy perch at lek, leans forward and inhales air ("grrr" part of call), then assumes very erect posture and, with "cowl" expanded, tail raised and curled undertail-coverts thrust out to form orange "globe" on each side, gives "aaa" call, then final bellowing "oooo" as it sinks back on perch to angle of c. 15 degrees beyond vertical; up to 15 or more subordinate males call and display on surrounding perches, do not defend any particular one, continually attempt to occupy dominant male's perch, also engage in paired displays with other subordinates; females regularly visit lek in groups, are highly aggressive towards one another; in Venezuela, there is usually a central lek, with various satellite leks, each attended by 2-3 males. Nest a thin, light platform of bifurcating twigs, with shallow cup made of fine terminal twigs of *Eugenia* tree, sited 3-6 m above ground in understorey tree. Clutch 1 egg; incubation period 26-27 days; fledging period not documented.
Movements. None recorded.
Status and Conservation. Not globally threatened. Locally fairly common in the Guianan forests, where populations concentrated around leks and easily detected. In Surinam, where most intensively studied, only one lek, comprising 8 males, in area of c. 9 km^2. Generally, numbers difficult to assess as, away from leks, wandering individuals generally silent and inconspicuous. Occurs in several protected areas, e.g. Imataca Forest Reserve and El Dorado (Venezuela), Iwokrama Forest Reserve (Guyana) and Brownsberg Nature Park (Surinam).

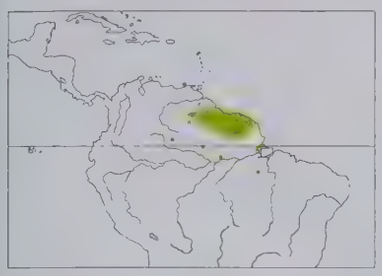
Genus *PROCNIAS* Illiger, 1811

64. Three-wattled Bellbird

Procnias tricarunculatus

French: Araponga tricaronculé **Spanish**: Campanero Tricarunculado
German: Dreilappenkotinga

Taxonomy. *Casmarhynchus tricarunculatus* J. Verreaux and E. Verreaux, 1853, Bocas del Toro, north-west Panama.
Almost certainly most closely related to *P. albus*, with which it shares several morphological characters. Monotypic.
Distribution. Breeds highlands of E Honduras (Sierra de Agalta), NW Nicaragua, Costa Rica and Panama (E to Azuero Peninsula). In winter in adjacent lowlands.



Descriptive notes. Male 30 cm, mean 210 g; female 25 cm, 145 g. Distinctive bellbird; bill very wide at gape, slightly longer than that of congeners. Male has head, neck and chest white, rest of plumage chestnut-rufous; bare black skin on lores and eyelids; three extensible bare blackish-grey wattles springing from base of upper mandible and corners of mouth; outer primaries modified, tips of inner vanes projecting beyond outer vanes and slightly hooked; iris dark brown; bill black, paler grey cutting edges; legs slate-grey, dull yellowish pads of toes. Female is olive-green above, duskier on primaries and their coverts, face with faint dull yellow streaks, underparts yellow, streaked olive-green, streaking reduced on throat and absent on crissum; cutting edges partially dull greenish-grey on lower mandible. Immature resembles female; male plumage acquired gradually, in course of c. 3 years, wattles begin to appear at c. 6-12 months. Voice. Male advertising call a very loud hammer-like "bock", either on its own or combined with less loud squeaks, whistles, and harsh or sharp monosyllabic or disyllabic notes; marked regional variation.
Habitat. Mountain forest, mainly at 1200-2300 m, sporadically higher following breeding; foothill and lowland forest, down to sea-level, in off-season.
Food and Feeding. Fruits, especially those of Lauraceae; very wide gape allows fruits of up to 25 mm in diameter to be eaten. Plucks items either while perched or during short aerial sally.
Breeding. Nest apparently unrecorded. Gonad data and male's displays indicate breeding mainly in Mar-Jun in Costa Rica. Male displays from treetop perch by calling and making short upward flutters; having attracted a female, descends to low perch in understorey tree, where mating takes place after further ritualized displays.
Movements. Pronounced altitudinal migrant, wintering in lowlands. Data from radio-tagging study revealed movement from highlands of NC Costa Rica down to lowlands of SE Nicaragua, thence to Pacific coastal areas of SW Costa Rica. In Panama most winter on Caribbean slope; vagrants, possibly displaced from former wintering areas, have occurred recently E to Panama Canal area.
Status and Conservation. VULNERABLE. Uncommon and local. Declining. Breeding areas include several protected reserves, most important of which are probably Sierra de Agalta National Park, in Honduras, Monteverde Forest Reserve, in Costa Rica, and La Amistad International Park, on Costa Rica-Panama border; in Panama found also in Coiba Island National Park, where it appears to be resident but is possibly only a non-breeding visitor. The primary reason for this species' decline is destruction of lowland forest to which it descends in non-breeding season; in N Costa Rica, for example, 35% of remaining lowland forest was removed between 1986 and 1992, and the little habitat still left is under severe threat. Most of this species' non-breeding areas are unprotected, but include Río Indio-Maiz Biological Reserve, in Nicaragua, Corcovado National Park, in Costa Rica, and Sansán-Pondsock Wetlands Ramsar Site, in Panama. Caribbean lowland habitats are under the most severe threat, and forest has virtually disappeared altogether in some parts; even nominally protected sites are facing the real risk of clearance for agriculture. Effective protection of all remaining lowland forest in the region is considered essential for the survival of this and several other globally threatened bird species.

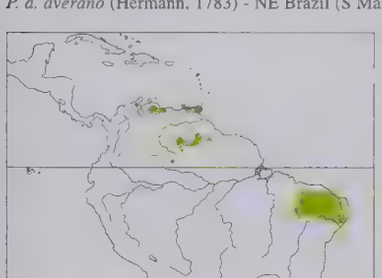
65. White Bellbird

Procnias albus

French: Araponga blanc **German**: Einlappenkotinga **Spanish**: Campanero Blanco

Taxonomy. *Ampelis alba* Hermann, 1783, Cayenne.
Almost certainly most closely related to *P. tricarunculatus*, with which it shares several morphological characters. Two subspecies recognized.
Subspecies and Distribution.
P. a. albus (Hermann, 1783) - E & extreme S Venezuela (E Bolívar, Cerro de la Neblina), the Guianas and adjacent N Brazil (N Roraima and N Pará, also isolated records E from lower R Negro).
P. a. wallacei Oren & Novaes, 1985 - Serra dos Carajás, in SE Pará (Brazil).



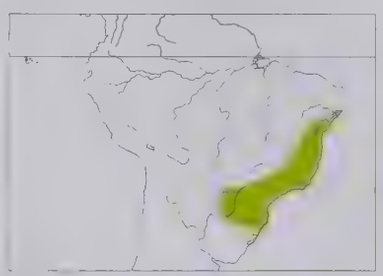
Descriptive notes. Male 28·5 cm, female 27·5 cm; male 210-215 g (*albus*), 219 g and 222 g (*wallacei*). Bill short, and very wide at gape. Male is unmistakable, one of the very few all-white landbirds; has single extensible wattle, black with short white star-like feathers, growing from base of upper mandible; outer primaries modified, tips of inner vanes projecting beyond outer vanes and slightly hooked; iris blackish; bill black, pale cutting edges; legs dark grey. Female is olive-green above, duskier on primaries and their coverts, olive-streaked yellow below; very similar to female of *P. tricarunculatus*, but shorter-billed, on average slightly smaller and shorter-tailed. Immature is similar to female; adult male plumage acquired gradually, wattle present but small at age of c. 1 year. Race *wallacei* differs from nominate in longer thinner bill, slightly grey-tinged throat. Voice. Male advertising call a very loud, sharp, bell-like "ding-ding"; also, very musical, more drawn-out, "doing doing".
Habitat. Humid forest; to c. 1250 m, probably breeding at higher levels. Generally occurs at lower elevations than *P. averano* (with some interdigitation) where ranges overlap in E Venezuela and Guyana.
Food and Feeding. Only fruit recorded; taken mainly in flight sallies, less often while perched; swallowed whole.
Breeding. Not recorded. Female seen to break off and drop fine twigs (of tree favoured as nest material by other cotingas) in Feb in S Guyana; movement upslope in first half of year and downward in second half probably indicative of breeding in about Feb-Jun; data on moult indicate less clearly defined breeding season than that of *P. tricarunculatus* or *P. nudicollis*. Male displays from treetop, with wattle greatly extended; calls with head and body held still, or, more loudly, utters one note as leans to right, then delivers second note with rapid leftward swing such that wattle (always hangs on right side of bill when call made with swing, although photographs suggest this may not be applicable for *wallacei*) flies out behind widely opened bill.
Movements. Little understood. Main range (presumed breeding area) centred in hilly areas of Guianan region, where some seasonal altitudinal movement (e.g. upslope movement recorded in Dec-Jun/Jul in SE Venezuela), with more extensive wandering into lowlands. Occasional records well away from main area, e.g. vagrant in Trinidad.
Status and Conservation. Not globally threatened, status uncertain; probably fairly common, but difficult to observe, and often locally distributed. Populations in remote highlands of E & S Venezuela and the Guianas should remain little disturbed for foreseeable future. Occurs in Canaima National Park and in Imataca Forest Reserve and El Dorado, in Venezuela.
Bibliography. Allen (1961), Burton (1976), ffrench (1991), Gilliard (1941), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1929), Herklots (1961), Hilty (2003), Meyer de Schauensee (1982), Murphy (1995), Oren & Novaes (1985), Quelch (1892), Ridgely & Tudor (1994), Roth *et al.* (1984), Sick (1993, 1997), Snow, B.K. (1973), Snow, D.W. (1973a), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992).

66. Bearded Bellbird

Procnias averano

French: Araponga barbu **German**: Bartkotinga **Spanish**: Campanero Barbudo

Taxonomy. *Ampelis Averano* Hermann, 1783, no locality = north-east Brazil.
Almost certainly most closely related to *P. nudicollis*, with which it shares several morphological characters in male (bare thigh patch, modification of outer primaries). Two subspecies recognized.
Subspecies and Distribution.
P. a. carnobarba (Cuvier, 1816) - extreme N Colombia (N end of Perijá Mts), N, SE & extreme S Venezuela, N Brazil (Roraima) and adjacent W Guyana; also Trinidad.
P. a. averano (Hermann, 1783) - NE Brazil (S Maranhão and N Ceará S to Alagoas).



Descriptive notes. Male 28 cm, one bird 178 g; female 26·5 cm, three birds 127-135 g. Distinctive bellbird; short bill very wide at gape. Male nominate race has black from lores down to malar area and throat, bare throat covered with "beard" of extensible black wattles, rest of head chocolate-brown; remainder of plumage silvery white, except for black wings, also bare patch of pinkish skin on outer side of tibia; outer three primaries modified, tips with rounded extension of inner vane; iris very dark (grey towards outside, brown towards inside); bill black; legs grey to black. Female is olive-green above, duller and duskier on head, predominantly yellow below, streaked olive-green, plain pale yellow crissum. Immature is similar to female; after first moult male acquires sooty crown and throat, before adult colours gained 1-2 years later, wattles begin to develop at c. 1 year. Race *carnobarba* male differs from nominate in having body plumage pale grey (not silvery white). Voice. Male advertising call a very loud hammer-like "bock", also a repeated, much less loud "tonk-tonk-tonk"; in Venezuelan populations two very different disyllabic calls reported, "kay-kong" in N and an unmusical, almost hissing "bisset" in S.
Habitat. Humid forest and mature secondary woodland; mainly in hill country, to c. 1900 m. Generally occurs at higher elevations than *P. albus* (with some interdigitation) where ranges overlap in E Venezuela and Guyana.
Food and Feeding. Fruits. In detailed Trinidad study, those of 44 species (40 trees, 4 vines) recorded, the families Lauraceae and Burseraceae, with large nutritious fruits, being especially important. Fruits plucked mainly in flight sallies, less often from perched position, and swallowed whole.
Breeding. Laying in Apr-Nov in Trinidad, probably May-Sept in N Venezuela. Male gives loud advertising calls from high treetop perch; when female is attracted, he flies down to low perch in understorey tree and makes ritualized posturing displays, exhibiting pinkish thigh skin; if female joins him on perch, display culminates in loud "bock", followed by mating. Nests recorded only from Trinidad; an extremely flimsy construction, light showing through, of thicker basal twigs with small cup of very fine twigs, 2·4-15 m above ground, usually in outer branches of tree at a little distance from forest edge. Clutch 1 egg; incubation period c. 23 days; fledging period c. 33 days. Breeding success apparently low: of five nests, only one successful.
Movements. Mostly resident. Well-studied Trinidad population essentially sedentary, with some movement of immatures into low country adjacent to hills. In N Venezuelan coastal mountains, at least part of population moves from lower levels (200-500 m) to higher altitudes in Apr-May, presumably to breed.
Status and Conservation. Not globally threatened. Uncommon to fairly common, and local, in most of range; relatively common in Trinidad. Race *carnobarba* occurs in several protected areas. Even where relatively common, as in Trinidad's Northern Range, male's selection of display territories on hill ridges leads to patchy distribution. Nominate NE Brazilian population subject to heavy trapping for cagebird trade, which, combined with habitat destruction, has led to its comparative rarity, but the bellbird's tendency to disperse or migrate over considerable distances probably enables this population to exploit widely separated forest fragments; it occurs in Pedra Talhada State Park and a few other reserves.
Bibliography. Chapman (1931), Coimbra-Filho (1971), Cracraft (1985), Descourtilz (1983), ffrench (1986, 1991), Forrester (1993), Hellmayr (1929), Herklots (1961), Hilty (2003), Hilty & Brown (1986), Keast (1985), King (1978/79), Meyer de Schauensee (1982), Murphy (1995), Oniki & Willis (2002), Pinto (1940, 1948), Ridgely & Tudor (1994), Schäfer & Phelps (1954), Sick (1993, 1997), Silveira *et al.* (2003), Snow, B.K. (1970), Snow, D.W. (1973a), Snyder (1966), Stotz *et al.* (1996).

67. Bare-throated Bellbird

Procnias nudicollis

French: Araponga à gorge nue **German**: Nacktgesichtkotinga **Spanish**: Campanero Meridional

Taxonomy. *Ampelis nudicollis* Vieillot, 1817, Nova Friburgo, Rio de Janeiro, Brazil.
Almost certainly most closely related to *P. averano*, with which it shares several morphological characters in male (bare thigh patch, modification of outer primaries). Monotypic.
Distribution. E Brazil (Alagoas and S Minas Gerais S to S Mato Grosso and Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).

Descriptive notes. Male 29 cm, 163-225 g; female 27 cm, 140-158 g. Distinctive bellbird; short bill very wide at gape. Male has plumage entirely white; skin of throat and area around eye bright greenish-blue, often bluer above gape (but can be greyish-blue or greener overall), bare except for inconspicuous black bristles; also bare patch of pinkish skin on outer side of tibia; outer three primaries modified, tips with rounded extension of inner vane; iris dark brown to dark grey; bill black, sometimes paler bluish-grey to lead-grey on lower mandible, especailly towards base; legs variable, dull brownish, purplish-flesh, dark grey, even whitish (very pale pink-grey). Female is rather dark and dull, dark grey head and throat, narrow ring of bare grey-blue skin around eye, some grey-blue also showing through scattered dark grey feathers on lores, tiny whitish streaks on throat and, especially, malar area and chin, olive above, wings dusky with dull olive margins, whitish or yellow with dark grey and olive streaks below (blacker and yellower on chest and breast side), pale areas increasingly larger downwards, belly predominantly pale yellowish, crissum entirely so; differs from females of congeners in darker throat, greyer and darker head. Immature similar to female; male acquires adult plumage gradually over course of c. 3 years, passes through intermediate stage with sooty-black crown. Voice. Male advertising call a very loud, explosive, metallic "bock", followed by series of similar but less loud notes tending to accelerate; of variable length, full performance may last 60 seconds.
Habitat. Humid forest; to c. 1000 m.
Food and Feeding. Fruits. In Alagoas and Bahia study areas, 16 fruit species (from 11 families) identified, among them four species of Myrtaceae, two each of Moraceae and Apocynaceae, and one each of Lauraceae and Burseraceae. In São Paulo study area, 10 species from 6 families (Arecaceae, Lauraceae, Moraceae, Myristicaceae, Myrtaceae, Sapindaceae). Data admittedly incomplete (cf. 44 species for *P. averano* in area less botanically rich). Individual fruits taken mainly in flight sallies, less often while perched; smaller fruits swallowed whole, larger ones in pieces; arillate fruits mandibulated until aril detached and seed dropped.
Breeding. Season in N of range (Alagoas and Bahia) probably Oct-Feb, based on male display and calling; in single known nest, laying probably late Oct. Male has permanent calling territory, usually in dense foliage in tree crown; rarely, displays on exposed perch. Nest a small cup constructed of epiphyte rootlets, some green moss on outside, inner lining of fungal fibres (*Marasmius*) mixed with moss and dry palm pinnules, placed 23 m up on twisted fork of vine stem hidden among tangle of woody vines in a 41-m *Manilkara* (Sapotaceae) tree. Clutch probably 1 egg, as suggested by nest size and presence of single nestling.
Movements. Not well understood; altitudinal movements likely, but uncertain whether or not regularly seasonal. Some evidence that the species may be migratory, at least in part, in SE Brazil and adjacent Paraguay; also, records from Argentina indicate that possibly only a transient visitor there. Has been suggested that it may follow complex migration route, perhaps linked to fruiting periods of trees.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Locally relatively common; rare in Argentina. Numbers have certainly declined as a result of destruction of E Brazilian coastal forests and severe trapping pressure; in spite of its extremely loud and unmusical call it is a popular cagebird, especially in Brazil. Occurs in a good number of protected areas. Principal threats to its habitat are urbanization, increased agricultural expansion and settlement, and associated road-building.

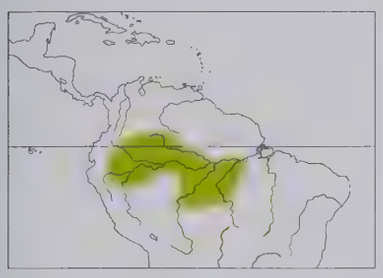
Genus *PHOENICIRCUS* Swainson, 1832

68. Guianan Red Cotinga

Phoenicircus carnifex

French: Cotinga ouette **German**: Blutkotinga **Spanish**: Cotinga Rojo Guayanés
Other common names: Red Cotinga (when merged with *P. nigricollis*)

Taxonomy. [*Lanius*] *Carnifex* Linnaeus, 1758, Surinam.
Relationships of genus uncertain, but apparently closest to *Rupicola*; further study required. Closely related to and forming a superspecies with *P. nigricollis*; could perhaps be considered conspecific, except for fact that ranges overlap in region of lower R Tapajós and perhaps between there and R Xingu. Monotypic.
Distribution. SE Venezuela (E Bolívar), the Guianas and lower Amazonian Brazil (E from E Roraima and Manaus area and, S of Amazon, from lower R Tapajós E to NW Maranhão).
Descriptive notes. Male 22 cm, 82 g; female 24 cm, 95 g. Distinctive; feathers of forehead directed forwards, half concealing nostrils, prominent bristly feathers around base of both mandibles, tarsus feathered on inner side, outer toe united with middle toe except for terminal phalanx. Male has crown (feathers glossy, plush-like), lower back to tail, and underparts from breast downwards bright red, rest of body blackish to maroon-brown, wings mostly rufescent brown, dusky on primaries, tail with dark brownish terminal bar; outer primaries highly modified, P6 normal in shape but short, P7 very short with attenuated, stiffened and twisted tip, P8-P10 somewhat stiffened, very narrow at base and broadest in middle, P10 very narrow at tip; iris red-brown; bill horn-coloured to brownish-orange; legs flesh-coloured. Female is larger than male in all measurements, is mostly olive, dull reddish on head and tail, rosy red from breast downwards. Immature male is like female, but with deeper red coloration, shorter wings. Voice. Male advertising call a 3-syllable "pee-chew-eet"; in aerial display, high-pitched whistle immediately preceded by whistling wing noise; monosyllabic "wheep" in arousal or alarm.
Habitat. Humid forest; to c. 600 m.



Food and Feeding. Apparently exclusively frugivorous; fruits from families Arecaceae, Lauraceae, Moraceae, Passifloraceae, Myrtaceae, Guttiferae, Melastomataceae and Euphorbiaceae recorded. Plucked either during aerial sally or from perched position.
Breeding. No information. Display period in Surinam Dec-May or, possibly, later. Male displays at lek, with several others (not necessarily in visual contact), calls noisily from perch c. 8-12 m up, leans slightly forward, wings drooped, tail lowered to expose brilliant red rump, frequently flies from one perch to another, alighting with swooping flight.
Movements. None recorded.
Status and Conservation. Not globally threatened. Rather rare and local throughout much of range, reasons for which not understood: locally fairly common in Guyana. Occurs in Imataca Forest Reserve and El Dorado, in Venezuela; almost certainly present in several other protected areas.
Bibliography. Blake (1950), Cohn-Haft *et al.* (1997), Haffer (1997b), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1929), Hilty (2003), Meyer de Schauensee (1982), Oren & Parker (1997), Ridgely & Tudor (1994), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992), Trail & Donahue (1991), Zimmer *et al.* (1997).

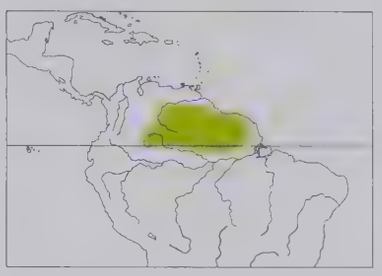
69. Black-necked Red Cotinga

Phoenicircus nigricollis

French: Cotinga à col noir **German**: Samtkotinga **Spanish**: Cotinga Rojo Cuellinegro
Other common names: Red Cotinga (when merged with *P. carnifex*)

Taxonomy. *P[hoenicircus] nigricollis* Swainson, 1832, Rio Negro near Barcelos, Brazil.
Relationships of genus uncertain, but apparently closest to *Rupicola*; further study required. Closely related to and forming a superspecies with *P. carnifex*; could perhaps be considered conspecific, except for fact that ranges overlap in region of lower R Tapajós and perhaps between there and R Xingu. Monotypic.
Distribution. E Ecuador, NE Peru, SE Colombia, extreme S Venezuela (S Amazonas), and upper and middle Amazonian Brazil (E to lower R Negro and, S of Amazon, to lower and middle R Tapajós and R Curuá).

Descriptive notes. Male 22 cm, 93 g; female 24 cm. Distinctive; feathers of forehead directed forwards, half concealing nostrils, prominent bristly feathers around base of both mandibles, tarsus feathered on inner side, outer toe united with middle toe except for terminal phalanx. Male has crown (feathers glossy, plush-like), lower back to tail, and underparts from breast downwards brilliant red to rosy red, rest of body glossy blackish, tail with black terminal bar; outer primaries highly modified, P6 normal in shape but short, P7 very short with attenuated, stiffened and twisted tip, P8-P10 somewhat stiffened, very narrow at base and broadest in middle, P10 very narrow at tip; iris dark brown; bill yellow-ochre; legs pinkish-red. Female is larger than male in all measurements, is mostly olive above, dull reddish on head and tail, red below. Immature male is like female, but with deeper red coloration, shorter wings. Voice. Male advertising call a loud "whea", often preceded by soft "wur"; in flight display, abbreviated version of "whea" sometimes given, immediately preceded by whistling wing noise; monosyllabic "yip" in arousal or alarm.
Habitat. Humid forest; to 400 m.
Food and Feeding. Almost exclusively fruit, but few details; only identified fruits *Trichilia* (Meliaceae). Also arachnid remains in one stomach.
Breeding. No information. In NE Peru, male seen to display, with several others in auditory contact, from 3-5 favoured perches, often horizontal sections of lianas, in lower middle levels of forest; calls and bobs head, makes twisting display-flights.
Movements. None recorded.
Status and Conservation. Not globally threatened. Generally rare and local; recorded at only two localities in Venezuela. Known to occur in some protected areas, e.g. Amacayacu National Park, in Colombia, and Cuyabeno Reserve, in Ecuador. Persecution by some indigenous peoples, who covet the red feathers above those of all other species, may have led to reduction of numbers in E Ecuador. Localized distribution and small population apparently typical of both species of red cotinga, which remain poorly known.
Bibliography. Brooks *et al.* (1999), Cracraft (1985), Friedmann (1948), Haffer (1997b), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Oren & Parker (1997), Ortiz & Carrión (1991), Peres & Whittaker (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Trail & Donahue (1991), Whittaker (1996b), Willard *et al.* (1991), Zimmer *et al.* (1997).



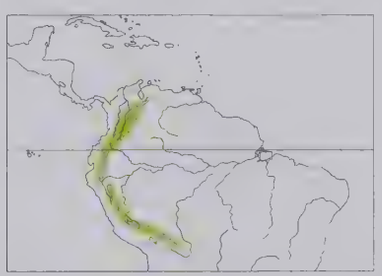
Genus *RUPICOLA* Brisson, 1760

70. Guianan Cock-of-the-rock

Rupicola rupicola

French: Coq-de-roche orange **Spanish**: Gallito de las Rocas Guayanés
German: Tiefland-Felsenhahn
Other common names: Orange Cock-of-the-rock

Taxonomy. [*Pipra*] *rupicola* Linnaeus, 1766, Cayenne.
Sometimes isolated with *R. peruvianus* in a separate family, Rupicolidae. Monotypic.
Distribution. E Colombia (locally SE Vichada S to Vaupés), S Venezuela (Amazonas, Bolívar), the Guianas, and locally N Brazil (from upper R Negro region E to Amapá, S to c. 100 km N of Manaus).
Descriptive notes. 27-32 cm; adult male average 218 g (2-year-old male 210 g, yearling male 200 g), female 203 g. Plumage unmistakable; bill strong, wide at base, becoming laterally compressed towards tip, rictal bristles absent, legs and feet strong, claws large and well hooked. Male has distinctive crest formed by two rows of flattened feathers, closely adpressed, ventral surfaces meeting along midline to form almost perfect semicircle; bright orange head and body, maroon subterminal line on crest; wings black with orange-buff to whitish margins, primaries with large white speculum; tail blackish with orange buff tips; secondaries very broad, inner ones with long silky fringes, feathers of back and uppertail-coverts similarly modified but to lesser extent; outer primary P10 with long slender tip, notched where tip joins expanded portion of inner vane; iris orange, yellower towards outside and sometimes on inner ring, sometimes red; bill yellow, base deep orange; legs yellowish-orange. Female is much duller than male, rather plain dark smoky grey, greyer on head (crest smaller than male's), somewhat bleached on outer webs of secondaries, belly buffier, crissum rufescent brown or ochraceous brown; iris paler and duller orange with greyer outer ring, bill blackish-horn with yellow tip and ridge of culmen, legs with dark brownish upper surfaces, dark horn on toes, and paler and yellower lower surfaces. Immature female is like adult; male at 1 year similar but freckled with orange, at 2 years mainly orange with small brown blotches, acquires full adult plumage at age of 3 years. Voice. Male calls at lek a variety of loud, raucous, crowing notes, usually uttered in confused chorus. Loud "waa-oww" during foraging.



Habitat. Humid forest, mainly near rocky outcrops; to 2000 m, mostly below 1200 m.
Food and Feeding. Mainly fruit, usually plucked in flight; also large insects, small reptiles and frogs. Fruits of many tree families and genera recorded; Annonaceae, Arecaceae, Lauraceae, Burseraceae, Myristicaceae, Meliaceae and Araliaceae probably most important. Nestlings fed largely fruit, also small snakes, lizards, and insects.
Breeding. Only detailed study Surinam, where laying Jan-May. Male displays on ground at communal lek, up to 50 or more (usually fewer) males present, each with own "court" on forest floor (courts sometimes only 1-2 m apart) but spending much time in low branches of trees just above, defends surrounding perches, regular bouts of aggressive noisy display with neighbours; on arrival of one or more females in trees above, all males fly down to respective courts, crouch motionless and silent, plumage spread to form patch of brilliant orange fringed with silky filaments of rump feathers and secondaries, females move down to low perches above, inspect displaying males; female eventually descends to a court, landing behind male, may nibble at fringes of his rump and wing feathers, until eventually he hops around and mounts; in Surinam study, nearly all matings performed by small number of males that occupied central courts. Nest a solid bracket of mud and plant material, weight up to 900 g, fixed to vertical rock face, usually in crevice, cave or under overhang, sheltered from weather; saliva apparently used to cement the structure. Clutch 1-2 eggs, mostly 2 in first clutches, 1 in 50% of repeat clutches; incubation period average 28·5 days; fledging period 33-44 days. Nesting success evidently variable: 9% (2 out of 23) in one year, 32% (10 out of 31) in another.
Movements. No long-distance movements recorded. Female with young in nest, fitted with radio transmitter, did not move more than 400 m from nest.
Status and Conservation. Not globally threatened. CITES II. Fairly common, but local. Requirement of rocky outcrops limits its range, but most populations occur in remote, little-disturbed areas. Present in several protected areas, e.g. Canaíma National Park, in Venezuela, Iwokrama Forest Reserve, in Guyana, and Raleigh Falls-Voltzberg National Park, in Surinam.

71. Andean Cock-of-the-rock

Rupicola peruvianus

French: Coq-de-roche péruvien **Spanish**: Gallito de las Rocas Peruano
German: Andenfelsenhahn
Other common names: Red Cock-of-the-rock

Taxonomy. [*Pipra*] *peruviana* Latham, 1790, Chanchamayo, Junín, Peru.
Sometimes isolated with *R. rupicola* in a separate family, Rupicolidae. Four subspecies recognized.
Subspecies and Distribution.
R. p. sanguinolentus Gould, 1859 - W Andes of Colombia and NW Ecuador.
R. p. aequatorialis Taczanowski, 1889 - Andes of W Venezuela (NW Barinas, Táchira), C & E Andes of Colombia, and E slope in Ecuador and Peru (S to Amazonas and N San Martín).
R. p. peruvianus (Latham, 1790) - C Peru (S San Martín S to Junín).
R. p. saturatus Cabanis & Heine, 1859 - SE Peru and W Bolivia (La Paz, Cochabamba).

Descriptive notes. 30·5-32 cm; one male 266 g, female 213-226 g (*sanguinolentus*). Plumage unmistakable; bill strong, and wide at base, becoming laterally compressed towards tip, rictal bristles absent, legs and feet strong, claws large and well hooked. Male has distinctive crest formed by two rows of fluffy feathers, ventral surfaces of which meet along midline to form semicircular casque; bright orange head, body and majority of lesser upperwing-coverts; rest of upperwing and whole tail jet-black, except for grey tertials (with mostly concealed darker bases); inner secondaries very broad and square-ended; primary P10 with long slender tip, notched where tip joins expanded portion of inner vane; iris pale dull orange-pink with yellow inner ring; bill intense golden-yellow; legs yellow. Female is dark chestnut-brown, blacker on throat and wings, crest smaller than male's, eyes pale blue to whitish, bill blackish, legs grey. Immature female is like adult; immature male similar but more orange, bird bred in captivity acquired adult male plumage at 15 months (perhaps unnaturally early, owing to unnatural social environment), but some acquire

subadult plumage with body feathers olive-washed and modified secondaries not of fully adult type. Races vary mainly in depth and shade of pigmentation of male's plumage, extent of grey on inner secondaries, and eye colour, female varying in parallel: *sanguinolentus* male has body plumage blood-red, eyes deep red with yellow inner ring, female eyes light red with grey inner ring or pinkish grey-brown; *aequatorialis* is bright orange, somewhat variable, has grey of inner secondaries restricted, eyes bright yellow or orange-yellow with yellow inner ring, female eyes whitish to brown; *saturatus* is deep orange-red, eyes usually pale blue to whitish with pale orange-yellow inner ring, female eyes sometimes brown. Voice. Male call at lek a loud "youii", less raucous than that of *R. rupicola*, also a clucking, long-continued "kip-kip-kip". Foraging birds, of both sexes, may utter loud, querulous "uankk" when disturbed.

Habitat. Montane forest, especially in ravines and along streams; 500-2400 m.

Food and Feeding. Fruit, large insects, and small vertebrates. Fruits of many plant families and species recorded, those of Lauraceae, Annonaceae and Rubiaceae being especially important; fruits plucked mainly in flight. Small lizards and frogs form significant part of food brought to nestlings; these are beaten against branch, macerated in bill, and presented to nestling head first.

Breeding. Little exact information for most of range. Breeding mainly in Feb-Jul in S Colombia and laying in Aug in Ecuador and Bolivia, but probably not well synchronized in low-latitude populations; onset of moult (presumably post-breeding) in Oct-Jan S of 10° S, indicating breeding in second half of year. Male displays at communal lek with up to 15 or more others, each with perch 4-6 m above ground, males in pairs, each bird performing ritualized bowing and head-bobbing displays towards the other, with much jumping, wing-flapping, bill-snapping and calling; displaying intense when females approach. Nest a bracket-like structure generally in shape of truncated cone, mainly of mud, concave cup lined with coarse vegetable fibres, attached 3-12 m above ground to rock face, once under concrete bridge; often groups of nests relatively close together. Clutch 2 eggs; incubation period 28 days; fledging period 42 to at least 48 days.

Movements. No long-distance movements reported; individuals range some distance from restricted breeding habitat, presumably while foraging.

Status and Conservation. Not globally threatened. CITES II. Uncommon to locally common or fairly common; generally local or very local. Large lek exists near Cock-of-the-rock Lodge, in Peru. Occurs in several protected areas, e.g. Cueva de los Guácharos National Park, in Colombia, Podocarpus National Park, in Ecuador, and Machu Picchu Historical Sanctuary, in Peru. Preference for steep, thickly vegetated ravines and streamsides ensures little human disturbance. The "National Bird" of Peru.

Class AVES

Order PASSERIFORMES

Suborder TYRANNI

Family PIPRIDAE (MANAKINS)

- Small arboreal birds of compact build, with short, rather wide bill, short wings and, except for males of a few species, short tail; feed mainly on small fruits, plucked in flight, and insects.
- 7-16·5 cm.

- Central and South America, and some offlying islands.
- Mainly tropical forest, a few species in scrubby woodland and thickets.
- 18 genera, 58 species, 146 taxa.
- 4 species threatened; none extinct since 1600.

Systematics

The classification of the Pipridae has long been controversial, and has still not been finally resolved. The long-standing and continuing difficulty has been that the "typical" manakins, consisting of 13 genera, form a well-defined group, while several other more or less manakin-like genera have characters that link them, variously, to the cotingas (Cotingidae) or the tyrant-flycatchers (Tyrannidae). The latter families are the two other main groups which, with the manakins, comprise the "tyrannoids", formerly combined in the superfamily Tyrannoidea. Although this taxon is now rarely employed, the three families are usually still kept together in a single suborder, the Tyranni, a useful grouping in this context.

P. L. Sclater, in 1888, separated the manakins from the two other related families on the basis of their "syndactylous" foot structure, in which the second phalanx of the outer toe is united with that of the middle toe, and on details of tarsal scutellation. This treatment was followed by R. Ridgway, in 1907. Later, however, it became apparent that too rigid an application of these criteria led to the probable misplacement of some genera. The syndactyly, for example, is shared with the cotingid genus *Rupicola*, and may originally have been an adaptation for perching on vertical stems. More recently, R. O. Prum has made a thorough reappraisal of manakin classification, based on extensive research into the structure of the syrinx and other anatomical, as well as behavioural, characters of the manakins and other tyrannoid genera. While it is clear that a number of changes very definitely need to be made to the traditional classification, there are several suggested ones for which the evidence is still somewhat uncertain, or even conflicting. Furthermore, it is likely that, within the near future, further research will throw new light on these and other controversial points. The classification currently adopted is therefore conservative, but incorporates the following generic changes, involving *Pipra*, the need for which seems incontestable.

Until recently, the genus *Pipra* was much the largest in the family, containing as many as 17 species. Such an arrangement has now been recognized as rendering the genus polyphyletic, and it has consequently been divided into three: *Pipra* and *Lepidothrix*, each with eight species, and *Dixiphia*, with a single species. In its syringeal anatomy *Lepidothrix* is much closer to the other manakin genera than to *Pipra*, from which it differs considerably in behaviour; its allocation to *Pipra* was based on the superficial similarity of the male plumage to that of others in the genus. *Dixiphia* is closer to *Pipra* but is not its nearest relative, and it, too, differs greatly in its behaviour. It is worth noting that *Teleonema*, a monotypic genus erected for the Wire-tailed Manakin (*Pipra filicauda*), has for some time been merged with *Pipra*, as this species, notwithstanding its extraordinary wire-like tail-feather projections (see Morphological Aspects), is a very close relative and allospecies of two typical *Pipra* species, the Crimson-hooded (*Pipra aureola*) and Band-tailed Manakins (*Pipra fasciicauda*).

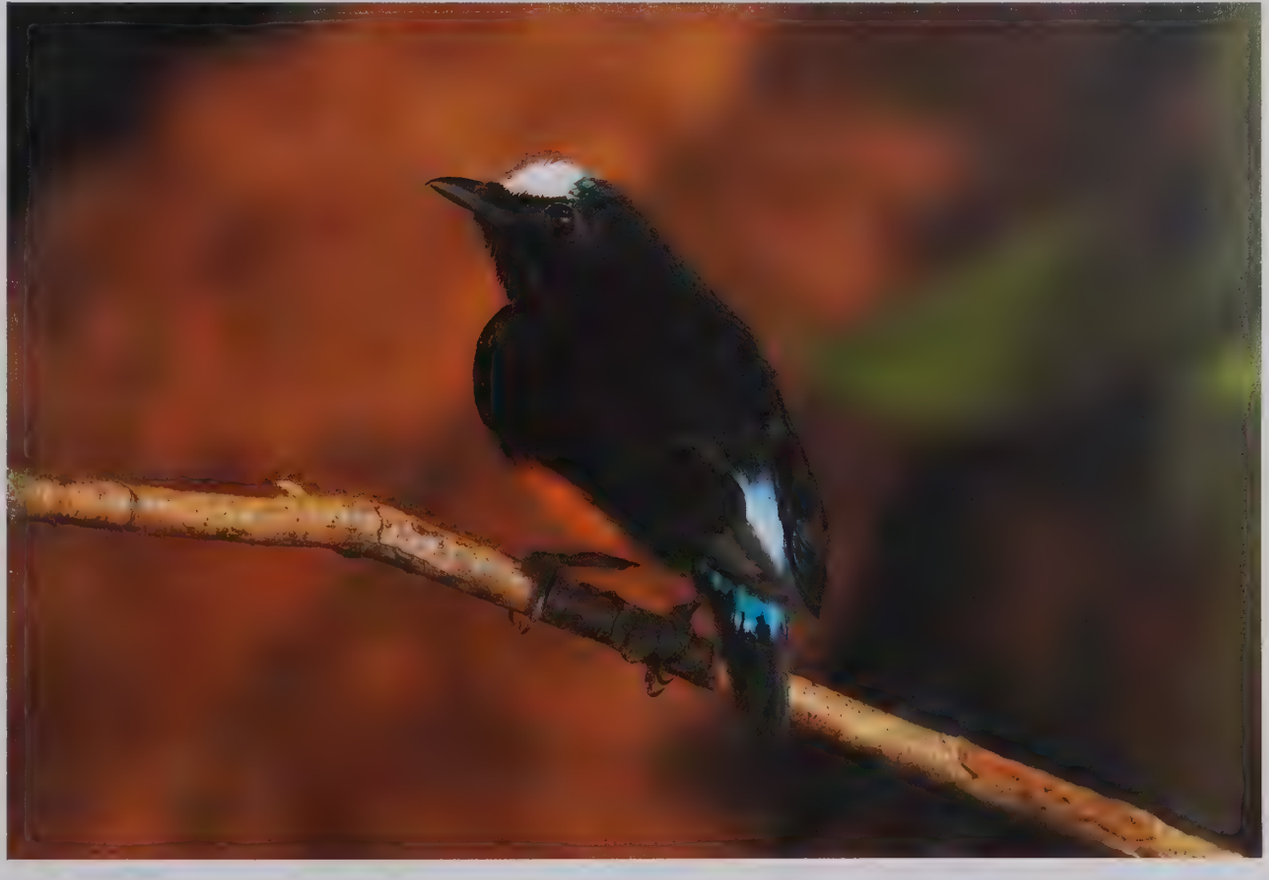
Although most manakins form a well-defined group, there are a few notable outliers. The genus Schiffornis, *for example, is only distantly related to the true manakins, and its taxonomic affinities are hotly debated. Recent genetic work suggests that the* ***Thrush-like Mourner*** *belongs in a clade alongside* Tityra *and* Pachyramphus, *and recent morphological analysis identified a monophyletic grouping of six genera that are currently spread among the Tyrannidae, Cotingidae and Pipridae (including* Schiffornis*). It seems incontestable that the boundaries between these families are inaccurately drawn at present, and that major taxonomic upheavals lie ahead.*

[*Schiffornis turdina turdina*, Linhares, Espírito Santo, Brazil.
Photo: Edson Endrigo]

As its scientific name suggests, the ***Broad-billed Sapayoa*** *is a taxonomic riddle, with no obvious relatives in any family. It is wider-billed and longer-tailed than true manakins, and the recent discovery of its nest points to non-piprid origins. It builds a hanging pouch, and the young are attended by both parents, two characteristics unheard of in manakins, but common in tyrant-flycatchers. Meantime, it is retained in its traditional position until its origins can be confirmed.*

[*Sapayoa aenigma*, Ecuador. Photo: Doug Wechsler/ VIREO]

The five genera placed at the end of the family are all taxonomically controversial. They have traditionally been treated as piprid, following the criteria used by Sclater and Ridgway, but almost certainly they are only distantly related to the typical manakins. Since there is no overwhelming evidence for placing them elsewhere, however, they are retained here. *Schiffornis* is especially puzzling, as an analysis by Prum of 19 characters, mostly anatomical, suggested that it is a member of a monophyletic assemblage of six superficially very diverse genera currently divided among the Pipridae, the Cotingidae and the Tyrannidae. Furthermore, recent investigations by U. S. Johansson and colleagues, who analysed sequence data from two nuclear genes and one mitochondrial gene, resulted in *Schiffornis* grouping with *Pachyramphus* and *Tityra* in a tityrine clade, whereas *Pipra*, *Manacus* and *Chiroxiphia* were found to be monophyletic.



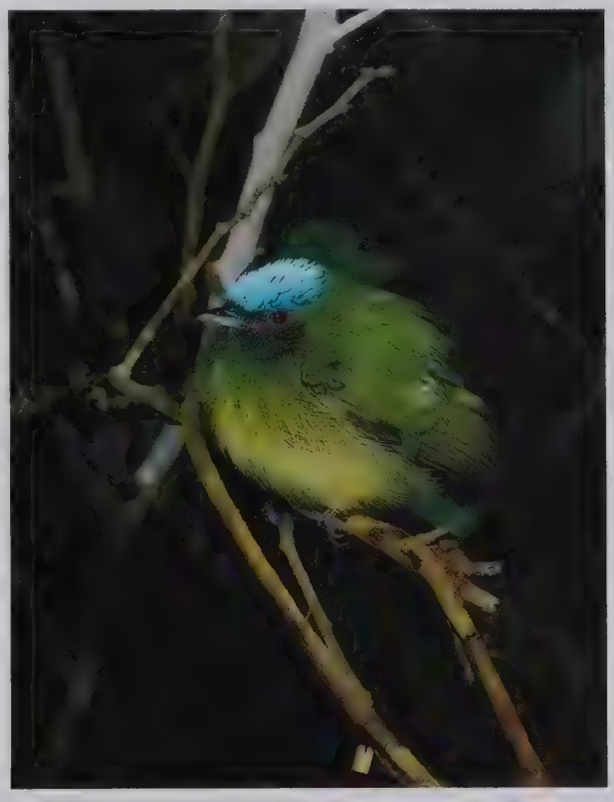
The genera *Piprites*, *Tyranneutes* and *Neopelma* also share with the cotingids and tyrannids some apparently derived character states, in other words, characters which have evolved later, rather than being ancestral to the tyrannoid stock. *Tyranneutes* and *Neopelma* may be closely related to each other. The monotypic genus *Sapayoa* contains the little-known Broad-billed Sapayoa (*Sapayoa aenigma*). It seems to be close to the tyrannids, and this likelihood has been strengthened by the recent discovery of its nest, which is pendent and pear-shaped, quite unlike a typical manakin's nest, and contained nestlings which were fed by both parents, indicating a social organization unlike that of a typical manakin.

At the species level, several taxonomic uncertainties remain. Further research may well indicate that, of the 58 piprid species currently recognized by most authorities, six should be split. These are the Blue-crowned (*Lepidothrix coronata*) and Blue-rumped Manakins (*Lepidothrix isidorei*), the White-crowned Manakin (*Dixiphia pipra*), the White-ruffed Manakin (*Corapipo leucorrhoa*), the Green Manakin (*Chloropipo holochlora*) and the Thrush-like Mourner (*Schiffornis turdina*). In most of these cases, the issue in question is that of whether lowland populations east and west of the Andes, presently treated as different subspecies, have diverged sufficiently to warrant the status of full species. Critical studies of voice, ecology and other aspects of their biology have not yet been undertaken, and any decision must necessarily be arbitrary. This is, of course, not a peculiarity of the manakin family; throughout the world, the same problem affects numerous closely related life forms with disjunct populations that have diverged to varying degrees.

A different and less usual situation complicates the taxonomy of the species of *Manacus*. Three of the four species in this genus come into contact with one another in Panama and Colombia, where they have produced narrow zones of hybridization. They could perhaps be considered to constitute a single species, as they differ mainly in the colour of the adult male plumage and are extremely similar in their courtship displays (see Breeding), as well as in their voice and ecology. On the other hand, the narrowness of the hybrid zones, and evidence

Until recently, Pipra *tended to be treated as by far the most species-rich genus in the family, with up to 17 species included. These were grouped together because of a superficial similarity in the colour and pattern of male plumage, but this arrangement has been shown to be polyphyletic. In particular, eight of the original 17 species, including the* ***Orange-bellied Manakin****, are closer to other manakin genera than to* Pipra *in terms of their syringeal anatomy. These same birds also differ in their courtship displays, and are thus removed to the genus* Lepidothrix. *Another unique form is placed in* Dixiphia, *leaving only eight species in* Pipra.

[*Lepidothrix suavissima*, Guyana. Photo: Doug Wechsler/ VIREO]



The typical manakins are small dumpy birds with stubby bills, short tails and large eyes. An almost universal feature is pronounced sexual dimorphism, males having relatively flashy and ornate plumage, and females being comparatively dull and greenish. This male ***Western Striped Manakin*** *is easily distinguished by his scarlet cap and red-streaked underparts, whereas the female (below) is relatively dowdy and anonymous, and is doubtless often passed over in the field without being identified. In most manakin genera, males are slightly heavier than females. The differences between the sexes can be explained by the breeding system prevalent in the family. While competition between males for the attention of females results in intense sexual selection for elaborate traits, there is no such competition between females and they have more to gain from camouflage.*

[*Machaeropterus striolatus*, Villavicencio, Colombia. Photos: Luis Mazariegos]

Young male manakins retain female-type plumage for one year at least. In their second moult a few male-type feathers often appear, resulting in intermediate plumage, for instance a green bird with a bright cap. In the ***Blue-crowned Manakin****, the adult male is usually black, so this might look like a youg male, but in fact it is an adult male of the race* caelestipileata*, in which males develop bright blue caps, but retain female-type body plumage throughout their lives. Green-bodied races occur south of the Amazon, black-bodied to the north. More than one species might be involved.*

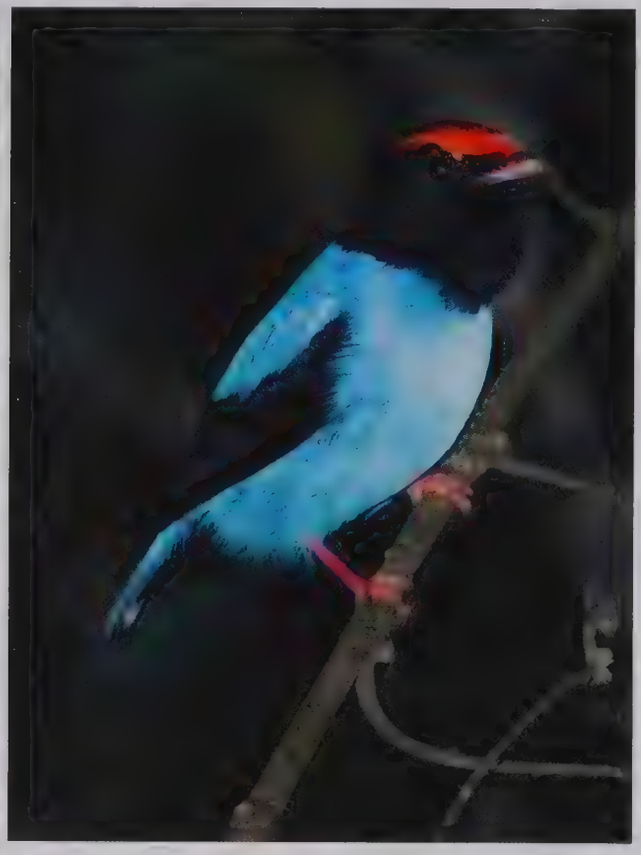
[*Lepidothrix coronata caelestipileata*, 107 km west of Puerto Maldonado, Madre de Dios, Peru. Photo: Alan Greensmith/ Ardea]

that, at a lek within one such zone, males of the two hybridizing populations kept to separate ends, with hybrid males in the middle, indicate a degree of reproductive isolation warranting their treatment as separate species. This case is further complicated by recent evidence, based on protein analysis, which suggests that the yellow throat colour of the male Golden-collared Manakin (*Manacus vitellinus*) has spread into adjacent white-throated populations in north-west South America, and that white-throated White-bearded Manakin (*Manacus manacus*) populations west of the Andes are more closely related to the Golden-collared Manakin than they are to populations of the White-bearded Manakin living east of the Andes.

Morphological Aspects

Manakins are small birds, mostly in the weight range 8-30 g. They are arboreal, typically possessing a stout body and short tail, and a short bill which is broad at the gape and without rictal bristles. The outer toe is partly united with the middle toe.

Most of the typical manakins (see Systematics) exhibit a high degree of sexual dimorphism. Adult males of the majority of the species are largely black, with patches of brilliant colour, either pigment-based red, orange or yellow, or structural blue, opalescent or white, mainly on the crown or other parts of the upperside. Females and young birds are olive-green or green above and paler below, and in some cases they are so similar to other, co-existing species that they present problems of identification in the field. Adult males not only have patches of brilliant colour but, in many instances, also have highly modified wing or tail feathers, most or, probably, all of which are used in courtship display (see Breeding).



In the genus *Manacus*, the four outer primaries are very narrow, stiff and slightly curved, the outer webs being extremely narrow. Whenever the bird flies, and not just during display. these produce a grasshopper-like whirring sound. The secondaries are more highly modified, their shafts being unusually thick and the outer webs very stiff. As described later (see Voice, Breeding), these are involved in the production of the loud snaps that accompany courtship display. In several other species, in the genera *Pipra* and *Ilicura*, the secondaries are modified to a much lesser degree, the shafts being thicker and the vanes somewhat stiffer than in the unmodified condition. In these species, snapping sounds, less loud than those made by *Manacus* species, are a feature of the courtship displays, but the mechanism of sound production is quite different from that of *Manacus* (see Voice). Two of the eight *Pipra* species, the Golden-headed (*Pipra erythrocephala*) and Red-headed Manakins (*Pipra rubrocapilla*), lack the modification and make no snaps when displaying, although other elements of their display are quite similar to those of their most closely related congeners.

The genus Antilophia *contains two large species with unusually long tails and forward-pointing crests. Although* Antilophia *is divergent from* Chiroxiphia *in plumage, behaviour and voice, the two genera are almost certainly quite closely related, and hybrids have been recorded. Like its relatives in* Chiroxiphia*, the male* ***Helmeted Manakin*** *makes loud and insistent calls throughout much of the day. Unlike them, it appears to have no organized, co-ordinated display. This species shuns extensive forest, preferring instead the strips of gallery woodland and small forest islands in the* cerrado *region of central Brazil, easternmost Bolivia, and northernmost Paraguay.*

[*Antilophia galeata*, Rio Negro, Mato Grosso do Sul, Brazil. Photo: Haroldo Palo Jr]

The genus Chiroxiphia *is consists of five rather large species. The males are strikingly patterned in black, sky-blue and red, the* ***Blue Manakin*** *being much the most extensively blue. They pass through a series of age-specific subadult plumages for about three years, before attaining fully adult plumage. This delayed plumage maturation relates to a complex dominance hierarchy at leks. Females, by contrast, are dull, although a few older birds have orange-yellow foreheads, partly concealed by green mottling.*

[*Chiroxiphia caudata.*

In males of *Machaeropterus*, the secondaries are extraordinarily modified in one species, the Club-winged Manakin (*Machaeropterus deliciosus*), and similarly so but to a far lesser extent in the other three species. The Club-winged Manakin's secondaries become progressively more curved from the outer end of the row inwards, the shafts becoming thickened distally, culminating at S6 and S7, which have the end of the shaft modified into a hollow, curved and pointed club. In display, male Club-winged Manakins raise the wings vertically above the back and vibrate their modified secondaries to produce a unique ringing sound.

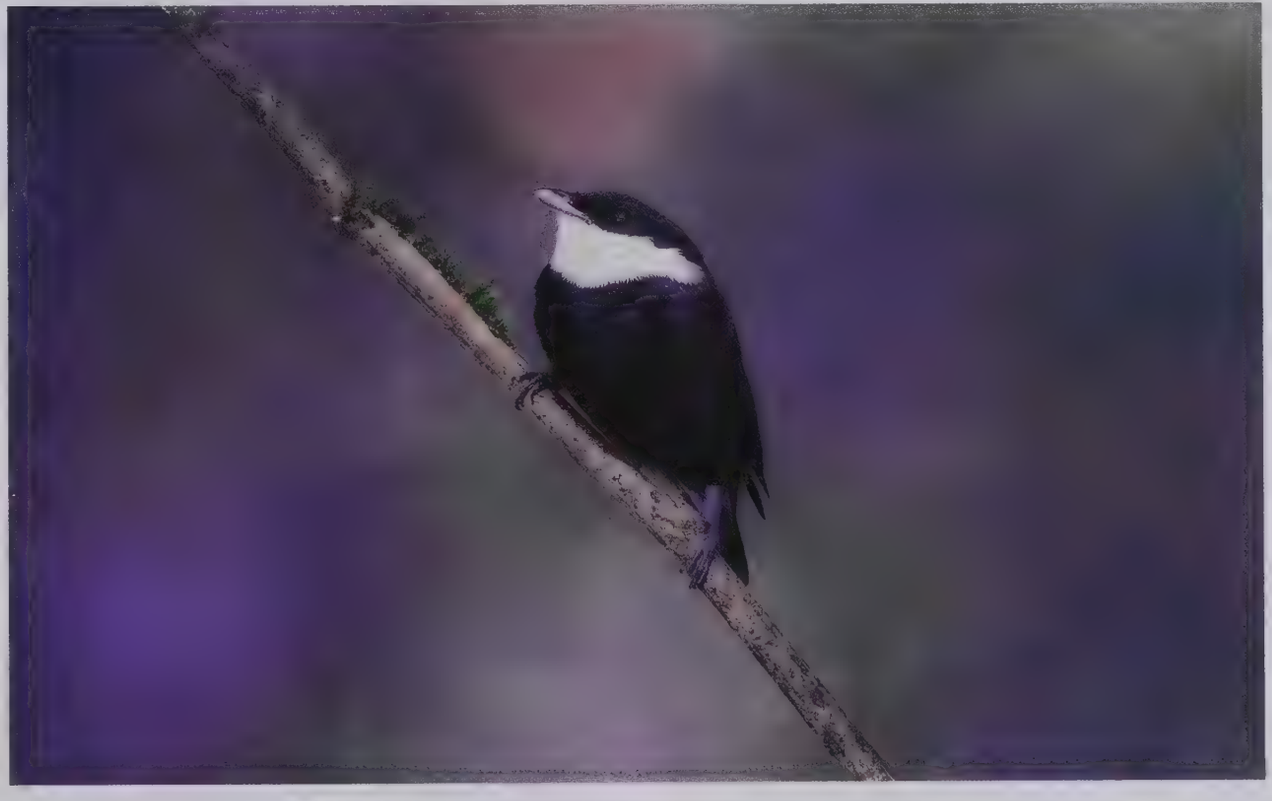
Another extraordinary and unique modification, in this case of the tail feathers, is exhibited by the Wire-tailed Manakin, which for that reason was for long placed in a monotypic genus *Teleonema*. The shafts are prolonged into fine wire-like filaments curving inwards and downwards, those of the outermost feather pair being longest and the others progressively shorter. The filaments of the outer pair, if straightened, may be up to 50 mm in length, about half as long as the head and body combined. As described later (see Breeding), these tail filaments, which are rather inconspicuous, are used in display not for visual effect, but as tactile organs; they represent one of the very few such organs known in the avian world. It is of particular interest that two very closely related parapatric species, the Crimson-hooded Manakin and the Band-tailed Manakin, have unmodified tail feathers. The group may have differentiated in the Quaternary period, at a time when the Amazonian forest was reduced to a number of isolated refuges; if so, this is a striking example of the rapid evolution of a secondary sexual character.

Male manakins in the genus *Chiroxiphia* have the three outermost primaries pointed, the shafts being thickened and the barbs reduced. It is not clear in what way, if any, these feathers are used in display, but they may be aerodynamically important in the fluttering jump and hover which is the most significant element in the uniquely complex courtship display of this genus. In three of the five species the central tail feathers are elongated to different extents, most extremely so in the Long-tailed Manakin (*Chiroxiphia linearis*). This, too, appears to be a case of rapid evolution, as four of the species, at least, are certainly very closely related. It is curious that only in the Long-tailed Manakin does the elongation seem great enough to enhance the visual effect of the courtship displays, which are very similar among all five species.

Turning to other aspects related to morphology, the relative sizes of the sexes, based on body mass, or weight, vary according to the genus involved. In most genera, males are slightly heavier than females, except during the latter's egg-laying period. Conversely, in *Pipra*, *Lepidothrix*, *Dixiphia*, *Corapipo* and, probably, *Masius*, it is the females that are the heavier, most markedly so in the case of the White-crowned Manakin, of which a large sample of both sexes in French Guiana showed the aver-

The male ***Pin-tailed Manakin*** *shows several unusual features, including a scarlet rump and frontlet, a pale iris, and lengthened tail feathers. Although this last feature is not unique within the family, occurring in more than one* Chiroxiphia *taxon, the species has no obvious close relative, and as such is placed in a monotypic genus. On behavioural evidence it might be most closely related to* Masius *and* Corapipo, *although the slightly stiffened and thick-shafted secondaries are reminiscent of* Manacus. *These feathers are used for producing similar, but quieter, snapping sounds in display.*

[*Ilicura militaris.*
Photo: John S. Dunning/
Ardea]



The genus Masius *contains a single species, the* ***Golden-winged Manakin****. The male looks mostly black when perched but golden-yellow when it takes to the air. The colourful flashes in the wings and tail are conspicuous during display flights, which are centred on a mossy log in on the forest floor. Another feature unique to this genus is the scale-like feathering of the rear crown, visible in the left-hand photograph. This species is one of few manakins that are confined to subtropical woodland, occurring at quite high altitudes in the Andes.*

[*Masius chrysopterus coronulatus*, Ñambí River, Colombia. Photos: Luis Mazariegos]

age weight of males to be 86% of that of females. In these five genera, displaying males execute rapid and complex flight manoeuvres. Owing to the modifications of the flight-feathers of the adult males of some piprid genera, the standard wing measurement is not a reliable measure of overall size.

In common with most other passerines, adult manakins undergo a complete moult immediately after breeding. Prior to that, the young birds first acquire a female-like juvenile plumage. Their subsequent plumage changes are not well known, and only those of the White-bearded Manakin and the Golden-headed Manakin have been studied in some detail. In these two cases, the juvenile plumage is replaced after a few months in an apparently prolonged moult of the head, body and wing-coverts, resulting in a plumage still of female type in both sexes, except that young males often acquire a few new feathers of adult male colour. At the next moult, which is complete and begins when the birds are a little over a year old, males acquire fully adult plumage.

The time taken by young males to gain the full adult plumage, with the concomitant structural feather modifications, varies according to species. As mentioned above, young male

The genus Corapipo *contains two species that are confined to Central America and northernmost South America. Males of both are glossy blue-black with a prominent snowy-white throat. The genus shares with* Heterocercus *and* Tyranneutes *a spectacular element of courtship display. A male* ***White-ruffed Manakin****, for example, flies up in steep spirals until he clears the topmost branches of trees, hovers momentarily, then plummets back to a display log far below on the forest floor. Indeed, while both* Corapipo *species live mainly in dark undergrowth, they are amongst the few manakins that spend any time above the rainforest canopy.*

[*Corapipo leucorrhoa altera*, Cerro Pirre, Panama. Photo: Luis Mazariegos]

The genus Manacus *contains four common species. These ball-like birds are small, neat and dumpy, with orange legs. The males are boldly patterned, like this* ***Orange-collared Manakin****, with a black cap, wings and tail, and either white or some intense colour on the collar, throat and belly. They have characteristic, lengthened throat feathers. In addition, their primaries are narrow, stiff and slightly curved; the shafts of their secondaries are unusually thick, and the outer webs are stiffened. This unusual wing feather design creates a whirring sound in flight, and is used to produce mechanical noises in display.*

[*Manacus aurantiacus*, Carara Biological Reserve, Costa Rica. Photo: Michael Gore/FLPA]

White-bearded and Golden-headed Manakins moult into adult plumage at the beginning of their second year of life, the moult commencing a little earlier in the season than that of the breeding adults. At the other extreme, males of the Long-tailed Manakin pass through three distinct, age-specific subadult plumages and do not acquire fully adult plumage until their fourth year. This delayed plumage maturation is related to the complex dominance system obtaining at *Chiroxiphia* leks (see Breeding), each subadult plumage stage apparently serving as a "badge of status" within a group of males of different ages.

For many manakin species, details of plumage sequences are not well known. Indeed, only for a small number of species is significant information available.

Habitat

The manakins are almost exclusively birds of tropical forest, living mainly in lowlands below about 1000 m. A few species are found at subtropical levels in the Andes, a notable example being the Golden-winged Manakin (*Masius chrysopterus*); none ascends as high as temperate levels, where several of their relatives, the cotingas, and many species of tyrant-flycatcher occur. Piprids live almost entirely in the lower and middle strata of the forest, rarely moving up into the high canopy.

Whereas some manakins, such as the *Lepidothrix* species, are rather strictly confined to humid primary forest or mature second-growth forest, others are tolerant of, or even prefer, more disturbed or more open woodland. Thus, the members of the genus *Manacus* prefer forest-edge habitats, quite recent second-growth woodland, and similar kinds of vegetation where there is an abundance of more or less closely spaced saplings with vertical stems, suitable for their leks (see Breeding). Many species, living mainly in the forest interior, come regularly to feed at fruiting trees at the forest edge. This is, in fact, much the easiest place for the casual observer to see them, as some of their most important sources of small fruits, especially small trees in the families Melastomataceae and Rubiaceae (see Food and Feeding), tend to be in greatest abundance along forest edges.

A general requirement for all typical manakins is the availability of a year-round supply of small fruits. Most humid forests in the Neotropics meet this requirement, and well-grown secondary forest, which, like forest edge, tends to be rich in suitable berry-bearing trees, can hold especially high populations of *Pipra* and *Manacus* species.

Within the forest, the display sites of the different manakin species, at and around which the males spend most of their time (see General Habits), are far from randomly distributed. Much of what is known about this aspect of habitat selection by manakins

The genus Machaeropterus *contains four rather aberrant manakins. Males are characterized by brownish plumage, a red or yellow cap, and bold streaking. Their vocalizations are also odd, usually brief buzzy rattles or very high-pitched frog-like notes. The secondaries are stiffened and modified in various ways, a feature taken to its extreme in the most divergent of the quartet, the* ***Club-winged Manakin****. In this montane species, the ends of the secondary shafts are hollow, curved and thickened into point-tipped clubs. In display, the wings are raised above the back and these feathers are vibrated to produce a unique ringing sound.*

[*Machaeropterus deliciosus*, La Planada Nature Reserve, Colombia. Photo: Luis Mazariegos]

*The **Black Manakin**, the sole member of the genus* Xenopipo, *looks somewhat out of place in the manakin family. It is longer-tailed than most of its relatives, and the male is unremittingly black, with no patch of colour. Indeed, its plumage and pale bill are reminiscent of male black-tyrants* Knipolegus. *Added to this, it catches insects on the wing, follows mixed-species flocks and has no conspicuous display. Its posture and large eyes are manakin-like, however, as are its vocalizations. In general, it is patchily distributed and difficult to find, though it can be fairly common in its favoured habitat of low-stature scrubby woodland, especially where this occurs on white-sand soils.*

[*Xenopipo atronitens*, Jeberos, Bajo Huallaga, Loreto, Peru. Photo: José Álvarez Alonso]

comes from studies carried out by M. Théry in French Guiana. Here, the leks of White-bearded Manakins and the display-logs of White-throated Manakins (*Corapipo gutturalis*) were in sites, such as east-facing slopes, which received sunlight at the two times of day when display activity is at its height, namely, the early morning and the afternoon. Similarly, the much higher display-perches of Golden-headed Manakins, 5-15 m above ground, were sited so as to be illuminated through gaps in the canopy to the east and west. The display sites of White-fronted Manakins (*Lepidothrix serena*), near the ground in the densest patches of forest, were nevertheless situated in places where there was most light, the males regularly alternating between a morning site and an afternoon site, each best illuminated at those times of day.

Recent studies being undertaken in southern Venezuela have corroborated these findings. Observations on four piprid species living in forest bordering the upper River Orinoco, in Amazonas, confirmed that the males, for their leks, selected positions along the vertical gradient where ambient light increased chromatic and/or achromatic contrast of their colour signals against the background or within their coloration patterns.

As mentioned above, the *Manacus* species prefer forest edge and secondary woodland to the interior of primary forest. Some other piprids, most notably those in the genus *Chiroxiphia*, occur, at least locally, in more open and drier types of woodland; the Lance-tailed Manakin (*Chiroxiphia lanceolata*), for instance, lives mainly in thick scrub and the lower growth of rather dry woodland. At the other extreme, the closely related Crimson-hooded, Band-tailed and Wire-tailed Manakins are found mainly in seasonally flooded *várzea* forest or in drier forest along watercourses. The three *Heterocercus* manakins also show a strong preference for seasonally flooded forest.

Two manakins occur in habitats which are atypical for the family. The Helmeted Manakin (*Antilophia galeata*) inhabits gallery woodland in the *cerrado* region of central Brazil, and the Black Manakin (*Xenopipo atronitens*) lives in patches of scrubby woodland and gallery forest in mainly unforested areas of the Amazon Basin. Both of these species are "true" manakins (see Systematics), and one of them, the Helmeted Manakin, is apparently quite closely related to *Chiroxiphia*. It is noteworthy, therefore, that they have not developed, or perhaps have lost, the elaborate courtship displays of their forest-living relatives and appear, instead, to have a more conventional social organization, although this aspect of their life is not well known.

The genus Heterocercus *amounts to a superspecies of three taxa, all of which have rather graduated tails. This feature is unique in the entire suborder Tyranni. In each member of the trio, males have bright crowns, and silky white elongated throat feathers. Like its congeners, and despite its Amazonian range, the **Orange-crested Manakin** is more a bird of* várzea *and low-stature woodland than of rainforest. Its remarkable display involves a spiral ascent until the bird is 60-100 m above the forest canopy, then a headlong plummet at high speed back to the understorey. During this rapid descent, the wings produce a hissing sound, and a loud pop.*

[*Heterocercus aurantiivertex*, upper River Tigre, Loreto, Peru. Photo: José Álvarez Alonso]

General Habits

Typical manakins share a combination of habits that marks them out from other Neotropical forest birds. Almost all of their move-

Five unassuming species occupy the genus Neopelma. *They are characterized by dull plumage in both sexes, and slightly longer tails and bills than is usual for the family. They are highly inconspicuous, and often ignored as unidentifiable tyrant-flycatchers (which they may well be!). Indeed, were it not for their distinctive voices, they would often go unnoticed. Until recently, only one species of* Neopelma *was thought to live in south-east Brazil, but vocal analysis revealed two song types. As a result, the* ***Serra Tyrant-manakin*** *was split from Wied's Tyrant-manakin* (Neopelma aurifrons), *which is otherwise extremely similar.*

[*Neopelma chrysolophum*, Intervales, São Paulo, Brazil.
Photo: Edson Endrigo]

ments, facilitated by the small size of the species, are quick and abrupt. When foraging, they do not hop about among branches or foliage, but perch motionless and make sudden aerial sallies. When displaying, they perform very rapid, often complex flights. Their actions when perched consist either of rapid "about-faces", so sudden that the foot movements are hard to see, or apparent "slides" along the perch, either sideways or backwards, by means of very fast, short steps, again too rapid to be followed by the unaided eye. Adult males spend a great part of their lives in more or less elaborate advertising display at fixed sites, either singly or in groups, and females undertake single-handedly all nesting and young-rearing duties (see Breeding).

The members of this family are generally unsociable when foraging and feeding, but some piprids do at times accompany mixed-species foraging flocks. Not uncommonly, however, several individuals may be found together at a fruiting tree, independently attracted by the same food source.

Manakins bathe communally in forest streams in the late afternoon, mainly between 16:00 and 17:30 hours. In his detailed study in French Guiana, Théry found that four species, the Golden-headed, White-crowned, White-fronted and White-throated Manakins, regularly bathed together, whereas the White-bearded Manakin bathed separately. Individuals took turns to bathe, the others perching a few metres away. Evidently, it is important to keep a keen lookout, as predators such as forest-falcons (*Micrastur*) and snakes were seen near bathing sites, and a bathing tanager (Thraupidae) was observed to be taken by a snake.

Roosting takes place on slender perches in the lower levels of the forest. Théry found that, in the breeding season, the roost-sites of adult males were always outside their display areas, and generally near a main feeding area. Two males with neighbouring display sites might sleep less than 5 m apart. Females roosted in different areas, either alone or with a dependent juvenile on the same branch.

It is, however, for their courtship displays that the manakins are famous. These displays involve the most elaborate and complex movements, and interactions between individuals, that are known among passerine birds. A main feature of the displays of many manakin species is that the males perform in groups, or "leks", which persist in the same place from year to year. Moreover, an adult male manakin's entire life, with the exception of the period of the annual moult (see Morphological Habits), is centred on the lek, at which he may, furthermore, be present for up to 90% of the daylight hours (see Movements), with brief absences for foraging. This is typical of, for example, the Golden-headed Manakin. Observations in Trinidad, where this species is numerous, reveal that the males may perch inactively for long periods, frequently emitting brief calls; at times they peck at excrescences on their perches, and, if there are leaves or vine tendrils hanging nearby, they habitually pull at these while hovering, thus keeping the area immediately around the perch clear of obstruction.

A highly complex social organization has been found to exist at these display arenas, where the males compete with one

The genus Tyranneutes *is probably only distantly related to the typical manakins. Two tiny, sexually monomorphic species are involved, one of which, the* ***Dwarf Tyrant-manakin****, is amongst the commonest birds in Amazonia. Despite this, it is rarely seen until its voice is recognized. Single males give their simple two-note song from static traditional sites, evenly spaced in the lower middle storey. This song can be heard throughout the day, and during all seasons.*

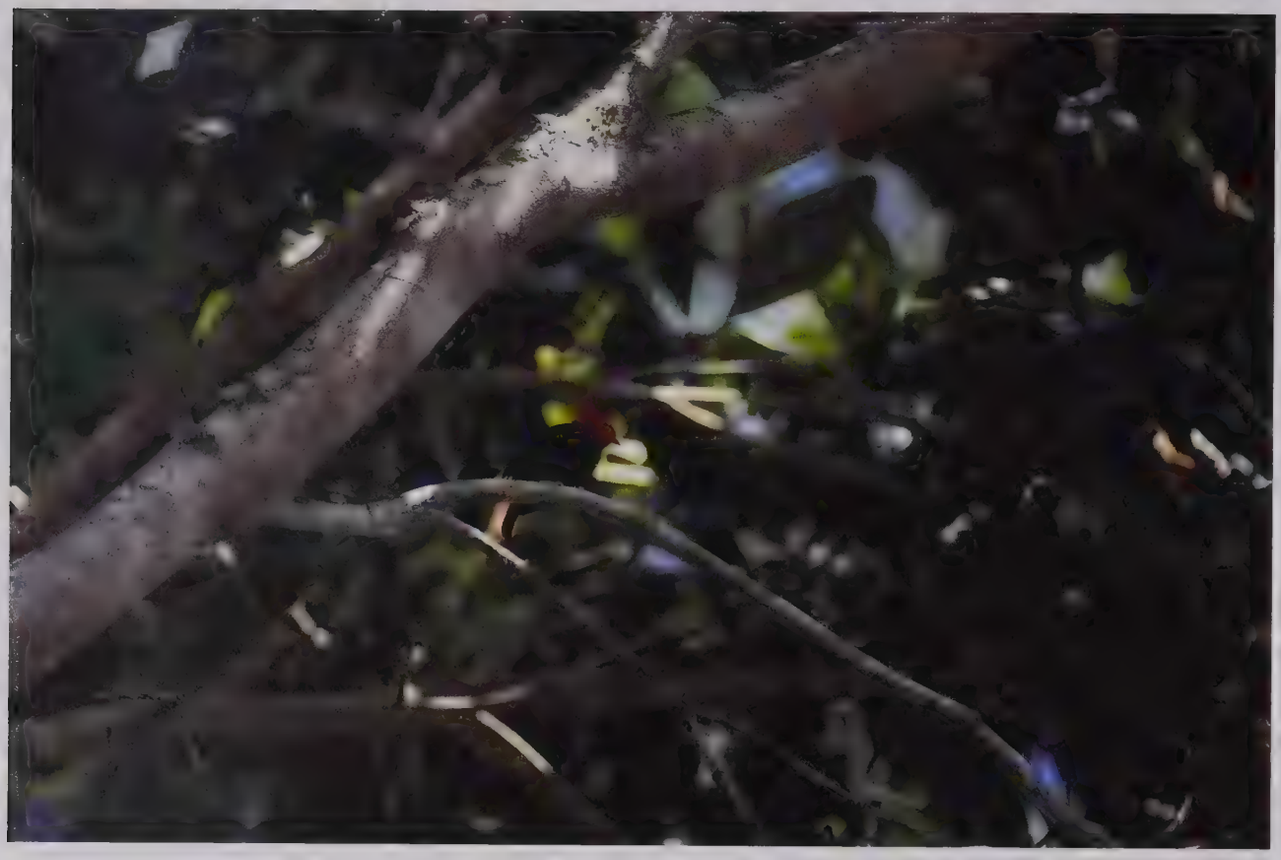
[*Tyranneutes stolzmanni*, Peru.
Photo: Ketil Knudsen]

Members of the genus Schiffornis *resemble typical manakins in their general form. They differ dramatically, however, in their loud and musical whistled vocalizations, pair-living social structure, dull monomorphic plumage, and nest architecture, factors suggesting that their true affinities lie elsewhere. This impression is emphasized by their size (bigger than most manakins) and their colour, which tends towards brown rather than green or yellow. Despite its name, the* ***Greenish Mourner*** *is quite rufescent, especially on the wings and tail. Like others in the genus, it is difficult to see, but easy to hear, and is often caught in mist-nets.*

[*Schiffornis virescens*, Serra da Cantareira, São Paulo, Brazil. Photo: Edson Endrigo]

another for the females, which visit the leks to mate. Nevertheless, displays are also performed intermittently when no female is present. As this intriguing behaviour is so closely associated with reproduction, however, it is discussed in greater detail in that context (see Breeding).

Voice



Manakins are generally rather silent birds, except at their display grounds. There, in association with their displays (see Breeding), the males utter a variety of mainly simple but often strange or striking calls. In addition, many species produce mechanical sounds, either in flight or when perched; the wing feathers and associated musculature of some piprids are specially modified to this end (see Morphological Aspects). These mechanical sounds are functionally equivalent to vocal sounds. Indeed, because of the rapidity of the bird's movements, it is in some cases by no means obvious to the observer whether a particular sound is vocal or mechanical. Furthermore, even when it is obviously mechanical, it is usually impossible to determine with the naked eye exactly how the sound is made. The following account is not exhaustive, but aims to give some idea of the range of sounds produced by manakins, and the contexts in which they are made.

Males of all of the well-studied piprids with fixed, often traditional, display territories or "courts", namely the typical manakins (see Systematics), have special advertising calls which they utter more or less regularly when at the display site. Away from the display area, both sexes are generally silent. These

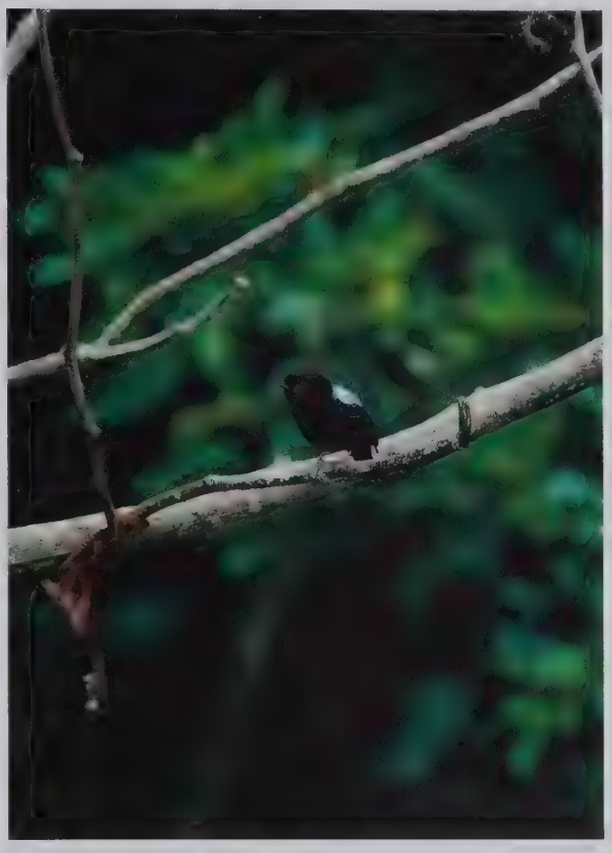
The ***Wing-barred Piprites*** *is typical of its genus but unusual amongst manakins in being a canopy dweller and a flock follower. Territorial males produce distinctive songs, and never perform displays or gather in leks. The only nest found to date was extraordinary within the context of the Pipridae in being sited in a cavity and lacking any form of suspended structure. The genus as a whole seems only weakly allied to true manakins, and it might have stronger ties to the Tyrannidae or Cotingidae.*

[*Piprites chloris chloris*, Intervales, São Paulo, Brazil. Photo: Edson Endrigo]

*The **Scarlet-horned Manakin** resides in tall forests, a habitat occupied by the vast majority of its relatives. Highest piprid diversity is found in primary forests of the humid lowlands, but many species occur elsewhere. Some tolerate, or even prefer, secondary vegetation. A few are found in dry forests, gallery woodland or the temperate zone. Manakins are essentially birds of lower or middle strata, although within these general constraints there is some niche segregation.* Pipra *species, for example, tend to travel in the middle storey, and* Manacus *in the understorey.*

[*Pipra cornuta*, SE Venezuela. Photo: Roland Seitre]

advertising calls, unlike those of many of the related cotingas, are mostly not very loud or far-carrying; they may be monosyllabic or they may be more complex, for instance a rapid phrase of a few notes, or a trill. Some are curiously unlike any "normal" sound expected from a bird. Thus, the male Golden-winged Manakin utters, at intervals that can be as short as 5-6 seconds but are usually rather longer, a low-pitched frog-like "nurrt", which is audible for only a short distance. This note seems to be designed to make any conspecific which may be in the near vicinity aware that he is in his display territory. Male Pin-tailed Manakins (*Ilicura militaris*) advertise their presence by emitting a soft, regularly repeated "see-see-see", usually of 5-8 notes, ending faintly and sounding plaintive to the human ear. In both of these species, males occupy display areas well separated from those of their fellows, and they can easily be overlooked by a human observer who is unacquainted with their voices. The lek-displaying *Pipra* and *Manacus* species, by contrast, have louder, more incisive advertising calls which are mutually stimulating, so that they tend to be given in bursts interspersed with more silent periods.



*The **Varzea Mourner** earns part of its English name from its specialized habitat requirements. It is widespread in Amazonia, where it is strictly tied to seasonally flooded forest, or* várzea. *This forest type is found along low-lying river margins and in the curved depressions formed by old ox-bow lakes. It tends to be much lower in stature than* terra firme *forest, and usually more tangled. The Varzea Mourner would be difficult to see in this dense swampy habitat were it not for its loud, distinctive song, and its aggressive response to playback.*

[*Schiffornis major major*, Anavilhanas, Amazonas, Brazil. Photo: Arthur Grosset]

The loudest advertising calls are given by the blue-backed *Chiroxiphia* species, notable for their co-operative courtship displays (see Breeding). Those of the four best-known species are strikingly different from one another. In the case of the Blue-backed Manakin (*Chiroxiphia pareola*), the dominant male of a group uses a single, incisive "chup", preceded by a rolling "wrrrr", to call up a subordinate male, which perches close beside him. The two then commence a duet of almost perfectly synchronized phrases, usually with 2-4 notes per phrase, "chup-chup, chup-chup-chup" and so on, the dominant male beginning each note about 0·04-0·06 seconds before the subordinate male. The very small time difference between the two birds gives the duet a curious quality, which has been aptly described as "a resounding phrase that rang through the forest like the clicking of billiard balls". In contrast, the duets of the Long-tailed and Lance-tailed Manakins, which replace the Blue-backed in Central America and northern South America, are musical and almost flute-like, and the intervals between the utterances of the two birds are longer. From the resulting medley of pure whistled phrases, these two species have earned the local name of *toledo*. The fourth of the well-known species in the genus, the Blue Manakin (*Chiroxiphia caudata*) from eastern South America, is different again; its duetting calls, irregularly overlapping, consist of phrases of sharply ascending and descending pitch, and sound to the human ear like a confused gabbling.

Quite different from the calls of the typical manakins, in both their form and the context in which they are given, are the calls of the three mourners in the genus *Schiffornis*, included

Long considered a montane race of the Blue-backed Manakin (Chiroxiphia pareola), *the* ***Yungas Manakin*** *inhabits subtropical forests in south Peru and Bolivia. It prefers cloudforest at moderate altitudes in the Andean foothills, but it has been recorded up to 2200 m. Like most* Chiroxiphia *manakins, the males are noisy but surprisingly difficult to see. This is a common bird, especially in Bolivia, where it is almost constantly audible in suitable habitat, even in small forest patches, or in narrow strips of bushy forest along streams in otherwise open country.*

[*Chiroxiphia boliviana*, Manu National Park and Biosphere Reserve, Peru. Photo: Bernard van Elegem]

within the Pipridae more for convenience than for any other reason (see Systematics). Far more easily heard than seen, the inconspicuously coloured males, as they move through the forest undergrowth while foraging, give a pure whistled phrase of several notes and characteristic rhythm at irregular, usually rather long intervals. The function of this vocalization is presumably that of advertising possession of a territory to neighbouring males, and the caller's position to interested females.

The closely related *Manacus* species are outstanding for the loudness of some of the mechanical sounds that accompany their displays. The main sound is a loud snap, produced at the moment when a bird takes off from a vertical stem bordering one side of its court, to land on another on the opposite side. It had been thought that the snap was caused by the modified secondaries brushing very rapidly against one another, but recent research by K. Bostwick and Prum, using high-speed video recording, has shown that the sound is made by the dorsal surfaces of the wings being clapped together above the back in a movement of extreme rapidity, apparently meeting one another at or near the swollen bases of the secondaries. This is made possible by an enlargement and modification of the muscles that raise the wing. A different form of the snap, the "roll-snap", is produced, much less frequently, by a perched individual; as it is made, the wings can be seen momentarily to be raised above the back.

Some other manakin species, when displaying, make a snap or less loud clicks. Only one such species, the Red-capped Manakin (*Pipra mentalis*), has been studied by means of high-speed video recording, and this has produced some remarkable findings. The display of the male Red-capped Manakin features three kinds of sound of this type, brief broad-frequency sounds with a very sharp beginning, and all three of them are produced in different ways, differing also from the mechanism used in the *Manacus* snap. One is produced by the wings alone, another by brushing the tips of the primaries very rapidly against the raised and fanned tail, and the third by striking the ventral surface of the wing against the side of the body and the thigh.

The extraordinarily modified secondaries of the adult male Club-winged Manakin are apparently responsible for the second part of a double mechanical sound, "tip-beeuwww", produced by displaying birds. For the "tip" the wings are flicked downwards, and for the "beeuwww", like the sound of a miniature trumpet, they are held up vertically above the back and vibrated, the expanded club-like endings of the middle secondaries presumably acting as resonators and producing harmonics that are apparently unique among avian mechanical sounds. Displaying males of the related Eastern Striped Manakin (*Machaeropterus regulus*), having less extreme club-like endings of the secondaries, make a resonant grasshopper-like whirring as they cling head downwards on a vertical perch, turning from side to side so rapidly as to become a blur. In the Western Striped Manakin (*Machaeropterus striolatus*) and the Fiery-capped Manakin (*Machaeropterus pyrocephalus*), but not the congeneric Club-winged Manakin, the shafts of the tail feathers are thickened and are probably used for mechanical sound production. It is significant that in the genus *Machaeropterus*, with these extreme specializations for mechanical sound, the syringeal muscles are reduced in comparison with those of other manakins. In particular, the Club-winged Manakin, the most specialized of all, has almost no syringeal musculature, and in its courtship display makes only two simple vocal sounds. The advertising call common to most other manakins has been replaced in this species by the mechanical trumpet sound.

Several members of the Pipridae produce mechanical sounds during a rapid, stereotyped fly-in to the display perch. The three members of the "*Pipra aureola* group", consisting of the Crimson-hooded, Band-tailed and Wire-tailed Manakins, make a soft "kloop", apparently with the wings, at the lowest point of the flight before swooping up and landing on the perch. Similarly, the White-throated Manakin produces a muffled "pop" at the moment of stalling in mid-air, with a flash of his white wing patches, just before alighting on his display-log. As described later (see Breeding), the Orange-crested Manakin (*Heterocercus aurantiivertex*), after a spiral ascent high above the forest canopy, makes a loud hissing sound as it plummets vertically downwards at high speed; again, it is thought that this extraordinary sound is made with the wings.

It is likely that further research employing high-speed video recording will reveal equally amazing methods of sound production in manakin genera that have so far been studied only by means of field observation and sound recording. It is probable

A few manakins are associated with drier forest or marginal habitats rather than intact humid forest. The tyrant-manakins in the genus Neopelma, *for example, tend to live in riverine growth, dense secondary vegetation, gallery woodland, bamboo or fern forest. The* ***Saffron-crested Tyrant-manakin****, pictured here, is a bird of forest islands in savanna regions, and of scrubby habitat where thin-stemmed brushwood is prevalent. It shuns humid forests, but is relatively common in low-stature woodland, especially where this stands on white-sand soils.*

[*Neopelma chrysocephalum*, Allpahuayo-Mishana Reserved Zone, Loreto, Peru. Photo: José Álvarez Alonso]

Most manakins are birds of the dark understorey and apparently never sun-bathe. Likewise, dust-bathing has not been reported for any member of the family. As with most birds, their chief comfort behaviour is preening, a habit they indulge in with a fair degree of enthusiasm, as these photographs testify. They show a ***Green Manakin****, perhaps a male, stretching its wings, nibbling the wing-coverts, and drawing its bill along the primaries to neaten the arrangement of barbs and barbules. Away from leks, manakins are relatively solitary birds, and no allopreening has ever been recorded. The genus* Chloropipo*, in which the Green Manakin resides, contains four inconspicuous species, each with a slightly longer tail than in typical manakins. Not only is the dull plumage of males identical to that of females, but these species seem remarkably quiet for a manakin: only modest vocalizations have been heard and no display has been recorded. There is evidence that* Chloropipo *is allied to* Xenopipo*, and it has even been suggested that the former should be subsumed within the latter. The traditional separation of these genera is maintained here, in part because the loud voice and wide repertoire of* Xenopipo *finds no match in* Chloropipo.

[*Chloropipo holochlora litae*, Anchicaya River, 40 km inland from Buenaventura, Colombia. Photos: Cyril Laubscher]

that modifications of musculature will come to light, and extreme rates of muscle contraction, comparable to those exhibited by hummingbirds (Trochilidae) in flight. This is an area of manakin research that is only just beginning.

Food and Feeding

Piprids feed mainly on small fruits, supplemented by insects and spiders. They usually pluck fruit in a rapid aerial sally from a nearby perch, landing with the food in the bill and then swallowing it whole, but they will sometimes pluck fruit from a perched position, if it is accessible by this means. Insects, and also small spiders, are likewise typically snatched from the vegetation following a brief flight. When termites (Isoptera) swarm after heavy rains, manakins may hawk for them from treetop perches, as do many other bird species. Some members of the family occasionally accompany mixed-species foraging flocks, and a few regularly do so. Among the few species for which the diets of the sexes have been analysed separately, females have been found to take a higher proportion of animal food than do males.

Sometimes, manakins join other birds in order to feed on insects disturbed by army ants. They usually do so only briefly, however, and they are not very efficient ant-followers, as they hardly ever sally to the ground. Moreover, most manakins use slender horizontal perches, and these are rarely to be found near ground level. E. O. Willis, who has made prolonged studies of ant-following birds in different parts of tropical America, found that in Amazonia the many manakin species rarely follow ants, but some of the same or closely related species attend ant swarms fairly often in Trinidad, Panama and eastern Brazil, where few specialized ant-followers occur. He concluded that the wealth of ant-following antbirds (Thamnophilidae) and woodcreepers (Dendrocolaptidae) which saturate the ant swarms in Amazonia makes ant-following rather unrewarding for manakins.

Manakins have a wide gape, and are able to swallow fruits that are very large in relation to the size of the bird. They often have to "juggle" large fruits in the bill, probably softening them in the process, before they can swallow them. The biggest fruits that the White-bearded Manakin has been recorded as swallowing, those of the rubiaceous plant *Coussarea paniculata*, were 19 mm long and 16 mm in diameter, and the largest ones recorded as eaten by the smaller Golden-headed Manakin, those of the burseraceous *Protium heptaphyllum*, measured 15 × 11 mm. The very wide gape is clearly important in enabling manakins to exploit fruits that cannot be eaten by considerably larger but less specialized frugivores, such as many tanagers.

A greater proportion of insect food is fed to the young than is eaten by the adults. For example, of 93 samples of regurgitated or defecated matter collected from below the display perches of White-bearded Manakins, insect remains were found in only four, the remainder containing seeds; by contrast, eight of 15 samples collected below nests with young contained insect remains. Nearly all of the insect remains consisted of hard parts of flies (Diptera) and beetles (Coleoptera). The Thrush-like Mourner, atypical also in other ways (see Systematics), is more insectivorous than the typical manakins and has been recorded as feeding large caterpillars to its nestlings.

The forests in which manakins live are rich in plants that bear small fruits, and the diets of manakin species are correspondingly varied. In a small area in Trinidad, White-bearded Manakins were documented as feeding on the fruits of 105 different plant species belonging to 27 families, and Golden-headed Manakins, less intensively studied, fed on 43 species. For both piprids, the trees and shrubs of species of Melastomataceae were of greatest importance numerically, and those of the Rubiaceae were second in importance. The major role of these two plant families in the diet of the Pipridae has been confirmed in studies elsewhere, especially in those undertaken by Théry in French Guiana.

Théry's research showed that manakins were the main dispersers of the Melastomataceae species and of the rubiaceous genus *Psychotria* present in his study area. They took an estimated 52-75% of the fruit crop of melastome species, and 61-89% of the fruit crop of *Psychotria*. In addition, they are very efficient dispersers. This is because their flight sallies enable them to select the ripest fruits, including terminal ones not available to other birds, and also because they feed in short bouts, shorter than the time taken by seeds to pass through the gut, resulting in good dispersal away from the parent plant. Moreover, and significantly, they tend to defecate at forest edges, in small clearings and along the courses of streams, sites that are suitable for the establishment of "pioneer plants", a category which includes most of the Melastomataceae and Rubiaceae. Seeds dropped elsewhere remain dormant for a long time, and in the event of a treefall they may germinate; in fact, a high percentage of such seeds in soil in French Guiana are from fruits eaten by manakins. In all these ways, manakins help to ensure the continuing abundance of their food supply.

As outstanding examples among small specialized frugivores in tropical forest, the adaptations of manakins to a diet of small

For some unaccountable reason bathing in water is very important to manakins. In the late afternoon, usually in the last hour of light, individuals of several species may visit streams or water-holes to bathe. In dry forests, or humid forests in the dry season, manakins are amongst the most frequent visitors to these sources of water. As such, it seems likely that this male ***White-crowned Manakin*** *is bathing rather than drinking. Indeed, the high water content of their fruit-based diet means that manakins drink infrequently.*

[*Dixiphia pipra cephaleucos*, Linhares, Espírito Santo, Brazil. Photo: Edson Endrigo]

Many piprids roost at or below human head-height, often at the edge of trails. Thus, they are amongst the birds most commonly found roosting by people walking through forests with flashlights. This female ***Blue-crowned Manakin*** *was found in this way as it roosted low down on a narrow stem. Dependent juveniles are known to roost alongside their mothers, but most adults roost alone. In all likelihood, males are always solitary at the roost, although those with neighbouring display arenas sometimes roost less than 5 m apart. In addition, the roosting behaviour of* Chiroxiphia *manakins is not yet known; perhaps co-operative groups of adult males roost side-by-side, just as they display.*

[*Lepidothrix coronata carbonata*, near Sucusari river, Peru. Photo: Michael & Patricia Fogden]

fruits, which typically have a high water content but low concentrations of nutrients, are of particular interest. An important aspect of these adaptations concerns the fact that the diversity of available fruits may be highly variable, both in regular seasonal succession and unpredictably at times of occasional scarcity. Manakins, therefore, in addition to being able to swallow fruits of a wide range of sizes, must be able to process them rapidly, assimilating the nutrients, mainly carbohydrates, efficiently and getting rid of the seeds as quickly as possible. Consistent with these needs is the fact that manakins' stomachs are small and their intestines relatively short, and they have no crop for storing food. Experimental studies by A. H. Worthington, using temporarily caged Golden-collared and Red-capped Manakins in Panama, revealed that the average passage time of small seeds through the gut was 15 minutes for the former species and 12 minutes, with a minimum of 7 minutes, for the Red-capped Manakin. Seeds with a maximum dimension of more than 5 mm did not pass through the gut but were quickly regurgitated, after an average of 7 minutes and 9 minutes, respectively, for the two species. Efficiency of assimilation of the nutrients in the pulp was variable, as has been found for other frugivores, but it was very high, at 86-98%, for non-structural carbohydrates, the most readily available energy source. These studies also showed that feeding bouts were short, lasting up to 2 minutes, as is the case in the wild, and the birds did not begin a session until the remnants from the previous bout of feeding had been evacuated.

Breeding

Like the majority of bird species inhabiting tropical forest, manakins nest solitarily. For all the typical piprids that have been studied, only the female is concerned with the nest. Manakins do not form pairs, but females that are ready to mate visit the males at their display grounds, where probably all matings take place. Studies of colour-ringed local populations of Golden-headed Manakins and White-bearded Manakins have demonstrated that most females mate with a single male in any one season, and the few that mate with more than one show a strong preference for one particular male. It is always a small number of dominant males at a lek that perform the majority of all matings; indeed, in the co-operatively displaying *Chiroxiphia* species, all matings are performed by the dominant male of the group. Since it may take several years to acquire a dominant position, males may not breed until they are several years old; females, as a rule, probably begin to breed at the age of about one year.

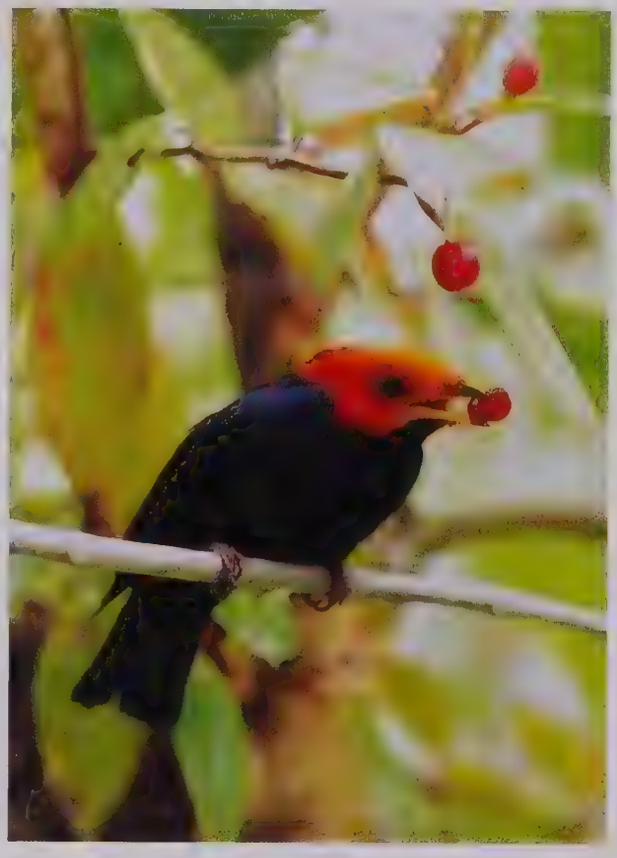
If there is one thing for which the family is renowned, it is its courtship displays. These displays, while not set off by such extraordinary feather adornments as those of some of the cotingas, or the birds-of-paradise (Paradisaeidae), are nevertheless remarkable in that they involve the most complex and elaborate movements, as well as the most highly evolved interactions among individuals, that are known among passerine birds. A predominant feature of this aspect of behaviour is that the males of many piprids display in groups at special leks, which are situated in the same places from one year to the next. The males compete with one another for the females, which visit the leks to mate. The spacing of males at a lek varies greatly, males of *Manacus* species being regularly as little as a metre or less apart, whereas several other species perform at dispersed or "exploded" leks, where males are within hearing distance of, but not in visual contact with, one another. Apart from during the period of the annual moult (see Morphological Aspects), an adult male manakin's whole life is centred on the lek, at which he may be present for up to 90% of the daylight hours (see Movements).

The complexity of manakin displays is two-fold, involving, on the one hand, the display movements and associated sounds, and, on the other, the complexity of social organization. The main features tend to be similar among members of the same genus. Limitation of space prevents a detailed description of all those which have been described, and the following is a necessarily selective summary.

The lek behaviour of the Golden-headed Manakin is a good example, central, so to speak, in terms of both its complexity

The true manakins are quiet birds when not displaying at their courts, but their displays are a different matter. Male White-bearded Manakins (Manacus manacus) *make a great variety of noises, including some loud snapping sounds produced by hitting the upper surfaces of the wings together at take-off. The* ***Red-capped Manakin*** *has recently been shown to make three kinds of sharp snapping or clicking sounds during its displays, all in very different ways. One is made by the wings alone, another is caused by brushing the tips of the primaries along the raised and fanned tail, and the third is made by striking the ventral surface of the wing against the side of the body and the thigh. The displaying male also makes sharp "psip" notes, and long descending "p'tsweeeeeee" calls. Were it not for sounds like these, manakin leks would be hard to find in the gloom of the forest. Luckily, leks are often so noisy that they announce themselves even when far off the trail.*

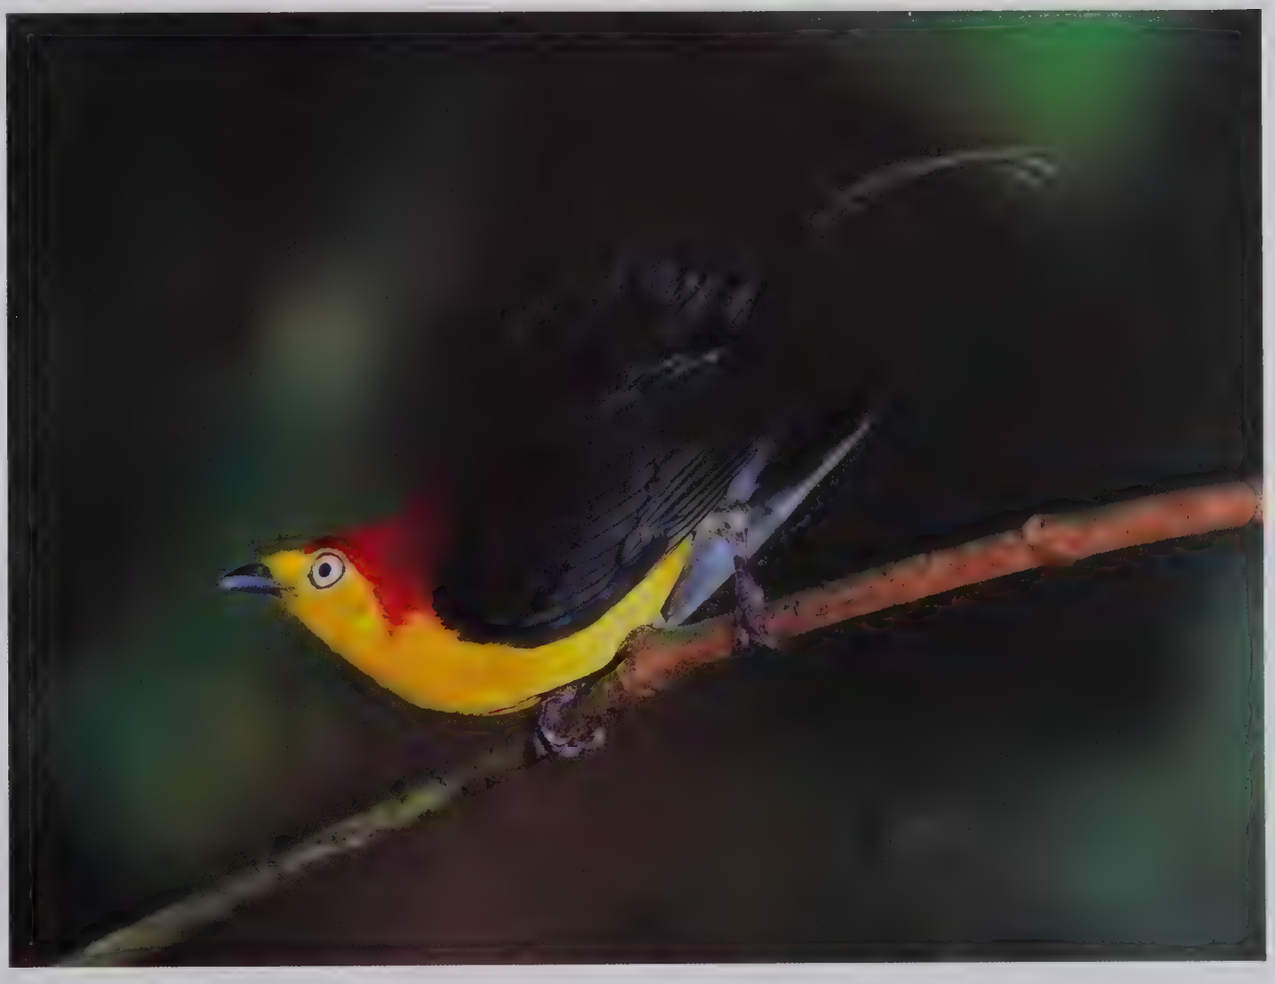
[*Pipra mentalis ignifera*, Panama. Photo: Marie Read]



*Manakins pluck fruit with gusto, usually during brief aerial sallies. To this end, they have a broad bill in relation to their body size, allowing them to swallow relatively large items. The **Golden-headed Manakin** is tiny, only 80-90 mm long, but it can eat fruit measuring 15 mm by 11 mm, a feat equivalent to a guan (Cracidae) swallowing a coconut! This individual is after more manageable fare: the fruits of a melastome shrub (Melastomataceae). These plants are regularly visited by manakins, and play an important role in manakin ecology. Manakins in turn play a role in melastome ecology by dispersing the seeds, thus ensuring the abundance of their own food supply.*

[*Pipra erythrocephala erythrocephala*, Santa Elena, Bolívar, Venezuela. Photo: Andy & Gill Swash]

and the relationship between the individual males, and it has been well studied. The males display under the canopy of lower-storey trees, on more or less horizontal small branches at a height generally of about 6-12 m. Each has a main perch, on which, if he is successful, mating takes place. The perches may be as little as 2-3 m apart and in the same tree, or 10 m or more apart and in adjacent trees. The number of males constituting a lek is variable, depending, at least in part, on the local population density. In Trinidad, where the Golden-headed Manakin is particularly numerous, leks can consist of up to twelve males. For most of the day, apart from short absences to forage, and for most of the year, except for the moult period, males are present at the lek. They often perch, inactively, for long periods, although they frequently utter short calls, and they keep the immediate surroundings of the perch clear of obstruction by continually attempting to remove any hanging leaves or vine tendrils.



Active display can occur at almost any time throughout the day, but is most frequent in the hour after sunrise and in mid-afternoon. Although it may occur spontaneously, it is conspicuously stimulated by the arrival of a female at the lek. The posture and movements involved in the display are highly stereotyped and very diverse, consisting of the following five elements. The first is known as "darting back and forth": with the legs fully stretched so that the red and white thigh feathers become conspicuous, and with the body held horizontally, the manakin makes rapid flights to and fro between its main perch and an adjacent one 1-1·5 m away, the wings producing a brisk humming sound in flight between the two perches; on landing, he at once turns about rapidly to face in the direction from which he came. In the second element, the "about-face", the bird makes rapid about-face turns, so quick that the foot movements cannot be clearly seen; these may be repeated while the bird remains in the same place, and each turn may be accompanied by an upward flick of the wings. Next is the "backward slide", in which the bird, with legs stretched, head held low and tail elevated, moves with very short and rapid steps, so that it seems to slide, backwards along the perch for about 10-20 cm; at the end of the slide, the tail is suddenly depressed and fanned and the wings are raised and held vertically above the back. Sometimes, halfway through the slide, the wings are suddenly spread horizontally and then closed again. The fourth display element, the "upright posture", is a stiff, almost statuesque posture, with head and body nearly vertical, which may be held for several seconds, the bird clinging to the side of the perch rather than perching on it; during this, the pupil is greatly contracted and the bill may be slightly opened. The fifth and final element is the "display-flight". This begins with the male leaving his perch and flying to a somewhat higher one some 15-25 m away, where he perches, facing the main perch, utters two or three sharp mono-

*Red pigments are prominent in manakin plumage, and in the strategies adopted by plants to attract manakins to fruit. Both plant and plumage are designed to exploit the spectral sensitivity of the avian eye. Typical manakins, such as the **Red-headed Manakin**, are very largely frugivorous, though they also eat a small proportion of insects and spiders, and feed their nestlings on a much higher proportion of animal matter. Some other genera, including* Schiffornis *and* Neopelma *(both only dubiously included in the family), are much more heavily reliant on insects.*

[*Pipra rubrocapilla*, Jenaro Herrera, River Ucayali, Loreto, Peru. Photo: José Álvarez Alonso]

Like many cotingas (Cotingidae) and birds-of-paradise (Paradisaeidae), male manakins of numerous species spend a large portion of their adult life advertising for mates at communal display sites, or leks. These leks are permanent and static, and females visit them to choose the father of their projected offspring. Fatherhood is only achieved by a few dominant males, none of whom make any contribution to parental care. As a consequence, through sexual selection, there is powerful evolutionary pressure on males to outdo their rivals when showing off to females, and it is this pressure that decorates them with gorgeous plumage, and shapes their marvellous displays. The latter involve the most elaborate movements and complex interactions found in any passerine birds. For their dances and costumes, the manakins are justifiably famous. Male ***Wire-tailed Manakins****, for example, are clothed in black, yellow and red. The shafts of their tail feathers are elongated into fine curved filaments, longest in the outermost pair. Thus attired they perform a complex co-operative display 2-4 m above the ground. This begins with co-ordinated flights between alpha and beta males, and reaches a crescendo when a female alights on the display perch. At this signal, the alpha male pivots his body back and forth, vibrates his wings, and approaches the female backwards. Then he does something remarkable: he tickles her chin with the shafts of his tail feathers. The use of an appendage as a tactile organ is very rare in birds; the lower photograph shows a male perched in readiness for this feat. If the female is suitably impressed, copulation ensues.*

[*Pipra filicauda filicauda*, Explorama Lodge, Quebrada Sucusari, Peru. Photos: Jordi Bas]

syllables, and then takes off and returns to the main perch in extremely rapid flight, uttering a succession of the same monosyllables which speed up and become sharper as he nears it; he approaches the main perch with a rapid downward swoop followed immediately by an upward swoop, and as he lands he utters a sharp buzzing call. Immediately on landing, he usually executes a backward slide.

As already mentioned, some or all of these displays are intermittently performed when no female is present. On the arrival of a female, however, display by all the males at the lek becomes intense and continuous. A female's behaviour is variable, being probably dependent on her familiarity with the lek and on her breeding condition; she may herself perform some of the display movements, but in less intense form. When ready to mate, she eventually goes to the main perch of one of the males. Occasionally, when the two are perched close together, she pecks very lightly at the male's brilliant orange crown feathers. Copulation may be preceded by any of the above-mentioned displays with the exception of the upright posture, which is used in more aggressive contexts. Mating often ensues immediately after a display-flight, the male landing beside the female and then mounting.

Although the details differ, the courtship displays of the Red-headed and Red-capped Manakins, both closely related to the Golden-headed Manakin, follow the same pattern. Very different is the lek behaviour of the White-bearded Manakin, the males of which display in compact groups on and near the forest floor. Each male clears a small "court", usually roughly circular or oval and about a metre across, removing all fallen leaves and other debris. Each court must have around it at least two, and generally three or four, vertical stems, usually of saplings; one of these is of special importance, as mating takes place on it. Courts are usually compactly grouped, sometimes even immediately adjacent to one another, although more often a metre or two apart. The number of courts at a lek varies greatly, and can number 50 or more in places where the manakins are abundant. At large leks, competition for central courts, where most of the matings take place, can be intense, leading to prolonged and violent fighting between the owner and a would-be usurper.

Like Golden-headed Manakins, male White-bearded Manakins are present at their courts for the greater part of the day and of the year. When not actively displaying, they utter simple, mainly monosyllabic calls. Bouts of display may occur throughout the day, but are concentrated in two periods, the hour after dawn and the early afternoon, and these are the times when females most often visit the leks. The display repertoire of this species consists of three distinct elements. The first of these, and the commonest display, involves jumps between vertical stems. Perched sideways on one of the vertical stems on the court's periphery, with the long throat feathers thrust forward to produce a "beard" that projects beyond the bill tip, the bird leaps across to one of the opposite stems, turning as he lands so as to face the way from which he came; at the moment of take-off, he makes a loud snap by striking the upper surfaces of the wings together above the back (see Voice). He may rapidly repeat the manoeuvre, either to and fro between two stems or irregularly around all the vertical stems surrounding the court. When a closely packed group of males is performing together, the impression is of a confusing collection of jumping black-and-white fire-crackers. The second element of display is less common, being performed only occasionally. After a series of snap-jumps ending low down on the mating perch, a male remains on the perch for a few moments, tense and quivering, with head and body pointing obliquely downwards; then, with a snap, he leaps to the ground, turning in the air, and on landing immediately leaps, making a curious grunting sound, back up to a higher position on the mating perch, and then, taking very rapid short steps, he "slides" down the perch while beating his wings. This sequence, of snap to ground, upward leap with grunt, and slide down perch, is in fact the stereotyped sequence of pre-mating movements. The third element, fanning, is a very distinct but comparatively infrequent display, most often directed to a female on her initial approach to a court. The male crouches, with head retracted between the shoulders, sways from side to side, and beats his wings with a low whirring sound; as the wings are raised, the long neck feathers are pushed forwards and upwards and appear as two flickering white puffs, one at each side.

When a female visits a male's court in order to mate, she usually first joins him in a co-ordinated dance of to-and-fro jumps between the mating perch and an adjacent perch, the two birds crossing one another in mid-air, until finally the female lands on the mating perch and remains there. This is the signal

Tending a display court is a full-time job. Adult male manakins often spend up to 90% of their day in attendance, and rarely stray very far from the area. Their only vacation is during the annual moult. This ***White-bearded Manakin*** *is busy maintaining a circular or oval court, roughly a metre wide, and free of litter. Each court has on its border two or more slender vertical stems, between which the owner makes rapid jumps accompanied by loud snaps. In larger leks, courts may be very close to one another, especially in the central area, sometimes leading to violent fights between rival males. Most matings take place in the central area of the lek.*

[*Manacus manacus trinitatis*,
Trinidad.

Ardea]

There is no pair bond in manakins. As soon as the female is ready to mate, she visits a lek and selects a suitable male. Her arrival invariably stimulates a flurry of activity amongst the contestants vying for her attention. Perched a few metres above the ground, the male ***Red-capped Manakin*** *pulls out all the stops. He hops back and forth on his perch, extending his thighs to show off his fine yellow "trousers". Every few seconds, he makes a rapid darting flight to an adjacent perch, accompanied by a loud whirring of wings. On landing, he immediately executes an "about-face" and returns to his original perch. Here he performs his* pièce de resistance, *the hugely fetching "backward slide", which involves holding the head down, elevating the tail, and moving with short rapid steps on stretched legs so that he seems to glide in reverse for 10-20 cm. At the end of this manoeuvre, the tail is pressed down and fanned, and the wings are raised vertically for a few moments, as if in triumph. Throughout this magical performance, a variety of sharp and sweet vocalizations are given.*

[*Pipra mentalis ignifera*, Soberanía National Park, Panama. Photos: Marie Read]

Although male manakins attend their display arenas for most of the day, and much of the year, they are often perched quietly, or just occasionally calling. The periods of most intense display activity are the hour after dawn and the early afternoon. In all species, the action is particularly frantic when a female arrives on the scene. The male ***Golden-collared Manakin*** *clears a court similar to that of the White-bearded Manakin* (Manacus manacus). *When the female selects a male to mate with, she and the male perform co-ordinated to-and-fro flights between the court's main vertical stem and the auxiliary stems, passing each other in mid-air.*

for the male to perform the pre-mating sequence described in the preceding paragraph, culminating in the "slide down the pole" on to the female's back.

The courtship behaviour of the three other *Manacus* species is extremely similar, and in most details in fact identical, to that of the White-bearded Manakin. This indicates a relatively recent splitting of the four species, which differ mainly in the presence or absence of yellow or orange pigment in the male plumage, and which interbreed to form narrow hybrid zones where their ranges meet (see Systematics).

A new level of complexity is reached in the lek displays of the "*Pipra aureola* group", comprising the Crimson-hooded, Band-tailed and Wire-tailed Manakins. In this case, additional males, referred to as "beta males", perform co-ordinated displays centred on the mating perch of a dominant male, "the alpha male", which alone mates with the females visiting that perch. The most striking feature in the co-ordinated display consists of precisely alternating display-flights similar to those of the Golden-headed Manakin. In quick succession, each male flies in and lands on the mating perch. As one bird approaches in rapid flight, the other, a moment before the incomer alights, leaves and flies back to the taking-off perch some 20 m away, then at once flies back in and displaces the first, and so it may continue for minutes on end. The beta males are younger birds, which, unlike the alpha males, are not sedentary but move around, competing with one another to take part in the older, established males' displays. The display repertoires of the three species are very similar, but with one extraordinary difference. In the culminating phase, the male, with tail raised, backs towards the female on the mating perch. Whereas two of the species have a tail of normal shape, the male Wire-tailed Manakin has uniquely modified rectrices ending in long wire-like projections, with which, when he has backed close to the female, he vigorously brushes her chin, rapidly pivoting his upturned body from side to side. This treatment is evidently agreeable to the female, as she perches quietly, facing him, with bill raised to present her chin.

The most elaborate display repertoire and social organization in the family, and perhaps among all birds, is that found in the genus *Chiroxiphia*. The display of the Yungas Manakin (*Chiroxiphia boliviana*) is unrecorded, but for the other four species the pattern is essentially the same. The Blue-backed Manakin may serve as the example.

Male Blue-backed Manakins display, and mate, on slender, more or less horizontal and typically slightly bowed stems or branches about 1-1·5 m above the ground in forest undergrowth. Each mating perch is "owned" by a dominant male, with which a small number of subordinate males are associated. The courtship display consists of four distinct stages. The first stage is duetting. The dominant male, perched at some height near his mating perch, calls at regular intervals until he is joined by one of his subordinates. The two then perch side by side, facing in the same direction and almost touching each other, and begin a loud synchronized duet in which the subordinate bird utters each note a fraction of a second after the dominant bird, the slight time difference producing a characteristic ringing sound (see Voice). After calling thus for a little time, the two birds fly down to the mating perch for the next stage. This second stage, the jumping display, has as its basic movement a fluttering jump. The bird crouches, and then jumps up with wings fluttering, bill pointing downwards and legs dangling, and hangs momentarily in the air before landing back on the perch; while in the air, he utters a strange vibrant, twanging call with the bill wide open. Typically, the two birds jump alternately, side by side, one beginning his jump as the other lands. The rhythmic twanging calls of the two jumping birds is often the main clue guiding a human observer to a mating perch, which is otherwise often difficult to locate in the tangled woody undergrowth. As the display proceeds, the jumps become lower and more rapid, and the calls become more irregular and confused, and take on a bleating quality. Finally, the last bird to jump emits a louder and more distinct bleating note, followed at once by one or more quite different, high-pitched "zeek" notes, after which both fly off. The third stage is the cartwheel dance. This is a modification of the jumping display and is performed in response to the arrival of a female on the mating perch. The two males turn to face her; the foremost male jumps up, hovers in the air, facing the fe-

*In the **Golden-collared Manakin** and its relatives, mating follows a set pattern. If the female is receptive, after a series of co-ordinated criss-crossing flights with the male between the vertical stems around the court, she lands on the mating perch and stands her ground as the male approaches. He lands below her, pauses for a moment with beard extended and wings quivering, then leaps to the ground at lightning speed, "bounces" up to land above her, and then "slides" down towards her and mates, with one foot on her back and the other on the stem. This species is a common bird in much of its Central American and Colombian range. It is very closely related to the White-bearded Manakin* (Manacus manacus)*, and indeed there is a distinct hybrid swarm at the junction of their ranges in the Cauca Valley of Colombia.*

[*Manacus vitellinus vitellinus*, Panama. Photo: Marie Read]

The most complex displays are performed by members of the genus Chiroxiphia. *Of these, the* ***Long-tailed Manakin*** *has been well studied in Central America, but the essential elements seem roughly similar throughout the genus. A typical display sequence proceeds as follows. The alpha male shares a slender horizontal perch with one or more subordinant associates (beta males). He calls near this perch until a beta male lands at his side and duets with him. Both birds then fly to the perch to perform a jumping display: the beta male crouches, while the alpha male flutters up into the air with bill pointing downwards and legs dangling. For a split second he hangs in mid-air, gives a peculiar twanging call, and then drops back onto the perch. At this point, the beta male performs an identical jump, and the sequence is repeated so that at any particular time one or other bird is in the air. The whole process accelerates, and the calls get more jumbled, until the alpha male utters a loud bleating noise then a screechy series of "zeek" notes, after which one or both birds fly off into the undergrowth.*
The so-called "cartwheel dance", performed when a female lands on the perch, is an escalation of this performance. Facing the female, the airborne male moves backwards, while the perched male shuffles forwards, so that the two birds rotate in front of her, as seen here (below).
In the Blue Manakin (Chiroxiphia caudata), *up to four collaborating males gather shoulder-to-shoulder. Each male jumps when it reaches the front of the queue and lands back down at the rear, while all males shuffle along the perch to keep in the same position. The resulting cartwheeling cacophony is not often witnessed, but it ranks as one of the most amazing spectacles in the natural world.*

[*Chiroxiphia linearis fastuosa*, Monteverde Forest Reserve, Costa Rica. Photos: Marie Read]

This photograph captures a pair of ***Long-tailed Manakins*** *performing the last act of the* Chiroxiphia *display. The terminal element in the sequence only begins if the female remains on the perch after the "cartwheel dance". If she does, the alpha male flutters around her in a bouncing, butterfly-like flight, occasionally perching momentarily. Whenever he alights near the female, he crouches facing her, revealing his shimmering blue mantle, and his crown patch, which is flattened into two crimson horns. Finally, he lands at her side and mounts, nipping her nape feathers for balance. Without exception, copulations always take place on the display perch, and always involve the alpha male.*

[*Chiroxiphia linearis fastuosa*, Monteverde Forest Reserve, Costa Rica. Photo: Marie Read]

male, and then moves back, still hovering, while the other male shuffles forward to take its place and in turn jumps up as the first bird lands behind it. Thus, the two males move in the form of a revolving wheel. As in the jumping display of two males by themselves, the cartwheel dance in front of a female, accompanied by the rhythmic twanging, becomes more and more rapid, seemingly frenzied, until it is brought to an end by the sharp "zeek". This is, in fact, uttered by the dominant male, the perch-owner, and is the signal to his dancing partner to leave, the latter's part in the display being completed. The fourth and final stage is the pre-copulatory display. If the female has stood her ground and remained on the mating perch, rather than, as often happens, leaving when the cartwheel dance ends, the dominant male begins a further, quite different and mainly silent display. He flutters around the female with a bouncing, butterfly-like flight, silently crossing and recrossing the display perch, every few seconds alighting momentarily and then flying on. If he alights near the female, he faces her, crouches with head lowered, thus exhibiting the blue patch on his back, and vibrates his wings. As the head is lowered, his red crown is presented squarely to the female, appearing shield-like as the two small lateral "horns" are extended. The female is thus presented with a red shield surmounted by a vibrating patch of shimmering blue. The female turns constantly to face the male, intently watching his performance. Occasionally, the male flies out to a more distant perch, faces the female, and, uttering a low twanging note, takes off with an audible click of the wings and resumes the bouncing flight. Finally, he flies to the mating perch, lands beside the female, and mounts.

The courtship displays of the other well-known *Chiroxiphia* species differ mainly in the first stage, the duetting calls being quite distinct. The display of one of them, the Blue Manakin, further differs in that three males regularly take part in the cartwheel dance, and occasionally more do so, perching close together and shuffling forward in line as the individual nearest the female jumps up.

By contrast, the two *Corapipo* species, the White-ruffed and White-throated Manakins, as well as the Golden-winged Manakin, are unusual in that they mate on fallen logs on the forest floor. The social organization of these three has been puzzling. Whereas some accounts describe single males in apparently uncontested ownership of a log, others mention groups of males, up to seven in one case, displaying together on and around a log in a more or less co-ordinated manner, and apparently moving as a group from one log to another. The most recent study of the White-ruffed Manakin, by L. Rosselli and co-workers, which included colour-ringed birds, indicates that each log is the property of a dominant resident male. When females visit for mating, which occurred at 12:45 and 14:47 hours in the two cases observed, that male alone is present, while earlier in the day other males, both adult and immature, are permitted to come and take part in communal, and at times co-ordinated, display among themselves or with the resident male. The function of these communal displays is probably that of establishing and maintaining a hierarchy of males within the local population.

The pre-mating display of the White-ruffed Manakin is one of the most elaborate and impressive. Following a series of flight displays close to the ground, ending with the female perching on the central part of the log, the male flies up from the log in a series of steep spirals until he is above the forest canopy; there he hovers briefly, while uttering one or more very high-pitched calls, before plummeting down to the display-log, landing beside the female and, at the moment of landing, making an explosive snap, almost certainly with the wings, followed instantly by one or two high notes and a sharp buzzing "wah", both probably vocal. Thereupon he immediately jumps over the female, hops towards her, and mounts.

Recently, it has been found that *Heterocercus* and *Tyranneutes* species also perform high flight displays. The most spectacular of such performances that is known is that of the Orange-crested Manakin. The male flies steeply upwards, in a series of spirals of decreasing size, to a height of 60-100 m above the forest canopy. From there it plummets down, gaining momentum for the first 15-20 m with rapid wingbeats, and then partially closes its wings and continues its descent in this posture, producing a peculiar hissing sound that becomes louder as the bird's velocity increases. When it is 2-3 m above the canopy it abruptly changes direction by nearly 90 degrees, producing

Manakins are some of the least egalitarian of birds. Females build the nest, incubate the eggs and rear the chicks alone. Males contribute nothing but sperm. The typical nest of true manakins is a small cup hung hammock-like between two horizontal forking twigs. It is bound to these twigs by cobwebs and plant or fungal fibres. In the ***White-collared Manakin****, the nest is unusually large, but the female's green plumage provides perfect camouflage in the dark understorey. To reduce the likelihood of predation further, she covers her nest with pieces of dead leaves and moss, and attaches a "tail" of vegetation. Although this increases the overall size of the nest, it confers extra camouflage in humid areas, where tangles of vegetation and strands of moss are common features in the undergrowth.*

[*Manacus candei*, Costa Rica. Photo: Michael & Patricia Fogden]

One of the perils of incubation in humid forests is the ever-present mosquito. These insects often settle on the head of incubating birds, and bite the small patches of bare skin accessible around the eyes and bill. In day to day life, small birds move too quickly for mosquitoes, and during the night roosting birds tuck their heads safely under their scapular feathers. An incubating bird is vulnerable because it must not draw attention to itself, and therefore never moves. Whether the unwelcome attention of mosquitoes is causing any discomfort to this female ***White-collared Manakin*** *is impossible to assess: it will sit motionless, with limitless patience, no matter how ruthlessly it is besieged.*

[*Manacus candei*, Costa Rica. Photo: Michael & Patricia Fogden]

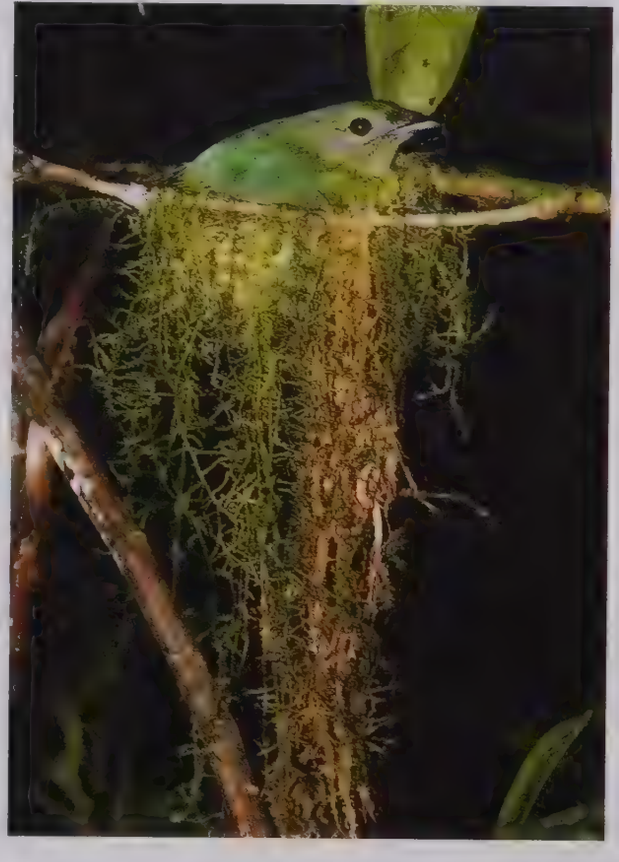
an explosive "pop". Finally, the manakin flies in a wide horizontal arc above the canopy, before entering the trees at great speed and returning to its terrestrial court.

The impossibility of adequately observing such a display in closed forest will be obvious. Detailed observation of the Orange-crested Manakin's display, by J. Álvarez, was made possible by the species' riverside habitat, enabling the whole performance to be seen from a boat. The high aerial displays of the two *Tyranneutes* species have been watched from a canopy crane and a canopy tower. B. Walther, watching from a canopy crane in Venezuela, has observed the Dwarf Tyrant-manakin (*Tyranneutes stolzmanni*) to fly straight up with very fast wingbeats from a perch at the top of a very tall tree to a height of 20-30 m and then "dive-bomb", in the manner of an aggressive hummingbird, back to the same perch. In Brazil, K. J. Zimmer, watching from canopy towers, has seen similar displays performed by the Dwarf Tyrant-manakin in Para and by the Tiny Tyrant-manakin (*Tyranneutes virescens*) near Manaus. How these spectacular displays relate to the species' behaviour at ground level is unknown. Male Tiny Tyrant-manakins call from low perches about 2-6 m above the ground, and make floating flights with rapidly beating wings between these perches.

A common feature of all the manakin lek displays that have been well studied, with individually marked birds, is that, in any one season, most or all of the matings are made by only one or a few of the males, and some males have no mating success at all. In large leks, the successful males are usually those occupying the more central display perches or courts. This at once raises a number of questions, which have been extensively discussed but not all unequivocally answered, concerning the factors that influence females in their choice of a mate. Among males, there is constant competition for central positions in a lek or, in the case of species with joint displays, for dominant status at a mating perch; therefore, a female would choose wisely by simply mating with central or dominant males, because they are likely to be efficient, vigorous individuals. This would not, however, explain the evolution of the males' extravagant displays and adornments, unless the central or dominant males also have the most spectacular performances, and yet the most careful observations and measurements of the few species studied in detail have failed to show any such correlation. However, one must bear in mind that birds certainly recognize many of their neighbours individually, presumably by using very subtle differences in appearance, voice and behaviour that humans cannot detect. In addition, there is some evidence that females are, as it were, "fascinated" by the males' adornments and show this by lightly pecking or touching them with the bill; thus, there would be scope for selection of males on the basis of their individual structural or colour differences. It is difficult otherwise to understand how the extravagant displays and associated plumage have evolved, as Darwin argued long ago. It has been suggested that competition between males, rather than female choice, may be the main selective agency affecting male physical characters. This is presumably the case for animal species in which the males fight for dominance, as with, for example, many mammals, but it seems highly unlikely to apply to manakins and other birds with highly ornate males, as the most elaborate displays are so clearly directed towards, and normally visible only to, the females.

Another intriguing question raised by such displays concerns those in which two or more males engage in some form of co-ordinated display, culminating almost invariably in mating being achieved only by the dominant male. What do the subordinate individuals get out of it? Long-term study of colour-ringed birds, most notably D. B. McDonald's study of the Long-tailed Manakin, has provided what is almost certainly the correct explanation: namely, that the subordinate males, in a ranking order based on age, are awaiting their turn to take over the dominant male's position when he loses it. Meanwhile, by displaying with him, they are gaining experience and maintaining the attractiveness, for females in the area, of the traditional display area and mating perch. This would not be a sensible strategy if annual mortality were high and senility in consequence rare, as is prevalent among many small north-temperate passerine birds. Adult manakins, however, are known to have high annual survival rates, of the order of 90%, and there is evidence that senility or loss of vigour may be quite usual, so that a younger male may have a very good chance of being able to take over the position of a dominant older bird. Even so, it is amazing that a male Long-tailed Manakin may have to wait up to ten years before achieving dominant status and being able to mate.

In many piprid species, nests are tiny, flimsy structures, not much larger than hummingbird nests, and easily identifiable by their hammock-like design. In some cases the structure is so loosely woven that the contents can be seen from below. Most manakins nest low down, and this ***Crimson-hooded Manakin*** *is no exception: she has built her nest on an open branch within a few metres of the ground. Despite its open aspect, her nest has been overlooked by predators due to its small size.*



[*Pipra aureola aureola*, Rorota, Rémire-Montjoly, French Guiana. Photo: Olivier Tostain/ EcoBios]

The evolutionary interpretation of piprid behaviour can be only briefly touched on. There is general agreement that an underlying prerequisite for the kind of social organization so strikingly illustrated by the manakins, characterized by conspicuously ornamented and conspicuously displaying polygamous males, and cryptically coloured females which single-handedly undertake all nesting duties, is the mainly frugivorous diet, which allows adults living in a rich forest habitat to feed themselves in a very small fraction of the daylight hours. Combined with this, there is good reason to suppose that the intense nest predation to which manakins, as other tropical-forest birds, are subject has resulted in their building very small, inconspicuous nests, capable of holding a maximum of two nestlings, which the female can rear alone, the presence of a brightly coloured male at the nest being positively disadvantageous. Under such conditions, intense sexual competition among males has arisen.

Exactly how the elaborate and even bizarre courtship behaviour has evolved in the Pipridae has been much discussed, with outstanding contributions by Prum. What has clearly emerged from Prum's analyses of manakin evolution, based on morphology, behaviour and DNA, is that the extraordinarily varied elements of their displays, including their spatial organization, have a strong phylogenetic component; in other words, they must have a long evolutionary history and, for the most part, are not recent responses to the present-day ecological conditions to which the different species are subject. The most likely evolutionary mechanism seems to be one proposed long ago by R. A. Fisher, who suggested that there has been some kind of linkage between genes producing extreme traits in males and genes determining female preference; put simply, females prefer the most extravagant males. Such a mechanism could, as seems to have occurred with the manakins, lead to the evolution of essentially arbitrary male characters and displays.

Like those of many birds of tropical forest, manakin nests, although not placed in thick cover, are small and hard to see; some are camouflaged. They are generally sited within a few metres of the ground, and the nests of some species are very low down. The result is that, while the nests of some manakins have never been found, those of a few of the most abundant species have been located in good numbers. Most of what is known of the family's breeding biology is therefore based on just a few species.

Breeding seasons of the few well-known species are long, extending over several months. Most of the available information originates from studies carried out north of the equator, in Central America and Trinidad around latitude 10° N, where the dry season, usually from about January to mid-May, is followed by a wet season lasting, usually with a minor interruption in September or October, until the end of the year. Under this seasonal regime, manakins begin to breed at some time in the dry period and continue into the wet, breeding usually being at its

In all manakins studied so far, the clutch consists of two eggs. The first is usually laid around midday, the second roughly 48 hours later. Beyond this, very few studies have focused on the piprid breeding cycle. There are no data about incubation period in the ***White-fronted Manakin****, but in several relatives it seems unusually protracted. The fledging period is shorter, and closer to what might be expected for birds of their size. In the genus* Lepidothrix*, there are records of incubation periods of 17-5-19 days, and fledging periods of 13-15 days.*

[*Lepidothrix serena*, Nouragues Natural Reserve, French Guiana. Photo: Olivier Tostain]

During the fortnight after laying female manakins spend most of each day on the nest. They break up the time spent incubating into a series of sessions, each lasting a minimum of one hour, and a maximum of several hours. All foraging is conducted in a few short absences, a strategy facilitated both by the abundance of small fruits in the forest understorey, and by the ease with which they are found. While incubating, female manakins shield the eggs from heavy downpours, as this ***Helmeted Manakin*** *has done; they also sit tight when approached by humans. Often, they only flush when a hand reaches out to touch them.*

[*Antilophia galeata*, Minas Gerais, Brazil. Photo: Anita Studer]

height in April-June. Individual females may make repeated nesting attempts in the course of a single season. Following the breeding season, adults undergo a complete moult which lasts, in the case of the White-bearded Manakin, for about 80 days. Studies of manakins in Trinidad and Panama have indicated that initiation of breeding is associated with, and apparently dependent on, an increase in the availability of fruit, and that the timing of this increase may be annually highly variable. Nevertheless, caution is needed in generalizing from findings in these two areas. This is demonstrated by the fact that, in Costa Rica, the White-ruffed Manakin, an altitudinal migrant (see Movements), was found to leave its breeding area when fruit was abundant and to return to breed at a time of overall scarcity.

A typical manakin nest is a very characteristic structure, easily recognized as such even if the owner is not seen. It is a small cup, constructed from vegetable fibres, leaf midribs, fungal rhizomorphs or other fine material, suspended in a fork between two horizontal diverging twigs, to which it is bound by cobweb or fungal rhizomorphs, or a combination of both. In places where large ferns are abundant, it may be suspended between two adjacent fern frondlets. The nest of some species is covered on the outside with pieces of dead leaves or moss, and may have a "tail" of dead leaves, moss or other material hanging down below it, thus increasing its apparent bulk but obscuring the rounded bottom of the nest cup. Such nests, when seen from the side or below, can be almost indistinguishable from the bunches of dead leaves that are commonly caught up in the forest undergrowth. The only known exceptions to this general form of nest are those of the Thrush-like Mourner, which builds a bulky nest in a quite different kind of site, and the Wing-barred Piprites (*Piprites chloris*), with a cavity nest. However, *Schiffornis* and *Piprites* are among the genera of uncertain affinities that are included in Pipridae only for historical reasons and for want of a clearly preferable alternative (see Systematics).

Perhaps the most extreme instance of adaptations designed to make the nest inconspicuous is that of the Orange-crested Manakin, the nest of which has only recently been discovered. Typically slung in a horizontal fork, the nest was so loosely woven, from vegetable fibres, that the observer could easily see through it from below. The incubating female adopted an exaggeratedly upright posture, with most of her breast well above the nest rim and the entire tail and undertail-coverts clearly in view, angled downwards, the nest itself being practically invisible. Thus, the visual impression was of a perched bird in a state of vigilance. There are clear analogies to this in the nesting strategies of some cotingas in the genera *Lipaugus*, *Xipholena* and *Procnias*.

Manakin eggs are rather large for the size of the bird. For example, those of the Red-capped Manakin measure 21·5 × 15·9 mm and those of the Orange-collared Manakin (*Manacus aurantiacus*) 20·5 × 14·9 mm. The ground colour is whitish, or pale cream-coloured, buff or grey, variably but often quite heavily marked with brown. So far as is known, the clutch size of all species is almost invariably of two eggs; occasional apparent single-egg clutches are probably the result of egg loss caused by predation. Eggs are usually laid around midday, the second about 48 hours after the first. Bearing in mind the small size of these birds, the incubation period is relatively long: a period of 16-17 days is recorded for the Golden-headed Manakin, 17·5-19 days for the Blue-crowned Manakin, 18-19 days for the White-bearded and Orange-collared Manakins, and 20-21 days for the Thrush-like Mourner. Fledging periods are less well documented, as nestling predation tends to be high, but they are not correspondingly long, being 13-15 days in the case of the Blue-crowned, White-bearded and Golden-collared Manakins.

Incubating female manakins spend long sessions on the nest, with relatively short absences for foraging. Thus, they devote a higher proportion of the day to incubation than do most small birds of other families. This is made possible by their diet of small fruits, which are usually abundant in the near vicinity. They are often very "tame", permitting a very close approach, even to the extent of allowing themselves to be gently touched. Sessions of incubation frequently last for more than an hour, and can be as long as 3-4 hours. The newly hatched young are pink-skinned, with a sparse covering of grey down, an exception being the chicks of *Schiffornis*, which have a copious down. They are fed with a mixture of small insects and small fruits, which the female carries mainly in her throat, although a few items may be held in the bill. Feeds are infrequent, usually one or two per hour for older nestlings. The female at first removes the chicks' droppings, but older nestlings defecate over the nest rim, so that the ground below is spattered with droppings by the time they are ready to fly. This is a rather surprising habit, as the low nests of, for instance, the White-bearded Manakin can

Newly hatched manakins are pink-skinned with a sparse covering of grey down. They are fed with insects and small fruit, many of which are carried back in the female's throat and regurgitated on arrival. In the ***Blue-backed Manakin****, as with most members of the family, feeds are relatively infrequent and insects are the commonest item. It is worth remembering that, despite her best efforts, she is statistically unlikely to raise her brood. Breeding success in piprids is exceedingly low. Of a large sample of White-bearded Manakin* (Manacus manacus) *nests, only 19% produced young. Data from other studies are roughly similar, suggesting that predation levels are extremely high. It is certainly a consequence of the heavy nest predation that manakin nests are so small and inconspicuous, and probably a result of this that the clutch has been reduced to two eggs, since the nest can only safely hold a maximum of two well-grown young. Taking this line of thinking further, if clutches are small they can be raised by a single parent, and the male is freed from his family duties. This skewed parental investment promotes female choosiness and intense sexual selection. Thus, heavy predation has probably played a role in driving the evolution of the elaborate behaviour and ornamentation so characteristic of male manakins.*

*The **Yellow-headed Manakin** is patchily distributed along the slopes of the Andes in Colombia and Ecuador. In general, it seems uncommon or rare, although this may have more to do with its behaviour than its true status. It is an inconspicuous understorey bird, easily overlooked, and it is probably commoner than records suggest. Nevertheless, its preferred moderate-elevation habitat is suffering intense pressure from agricultural expansion and settlement. It is currently treated as Near-threatened, but further surveys are required, perhaps using mist-nets, to gain a clearer picture of its distribution and abundance.*

[*Chloropipo flavicapilla*. Photo: John S. Dunning/ Ardea]

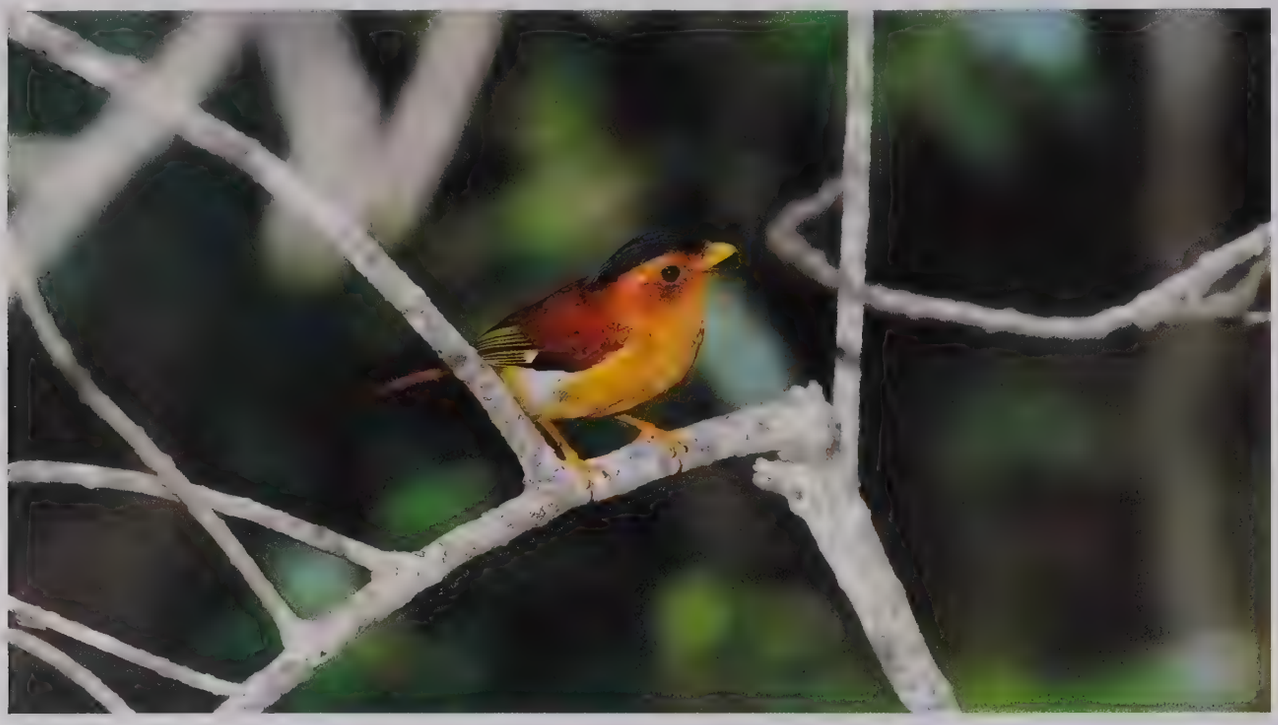
be less than a metre above ground and clearly visible from below. Presumably, potential predators are not attracted in this way.

Be that as it may, nesting success of all piprid species studied is very low. The following figures take into account only nests located before the clutch was complete, as those found later are biased in favour of success. In terms of percentages of nests that yielded at least one fledged young, the success rate for 23 Orange-collared Manakin nests was 13% and that for 227 nests of White-bearded Manakins was 19%. For *Pipra* species, the higher nests of which are more difficult to find, extremely low success has been recorded; of eight nests of Red-capped Manakins and seven of Golden-headed Manakins, not one produced any fledglings.

With such low breeding success, followed probably by a considerable post-fledging mortality, about which nothing is known, it follows that, for populations to remain stable, adult survival must be high. This has been found to be so for the four species to which long-term studies have been devoted. Thus, for the White-bearded Manakin in Trinidad an annual survival rate of at least 89% has been recorded, with individual males living for a minimum of 14 years and females for 12·5 years. In the same area, male Golden-headed Manakins were recorded as surviving for at least 11·5 years and females for 12 years.

Movements

The White-ruffed Manakin in Costa Rica breeds in the mountains, mainly at altitudes of 400-900 m, descending to adjacent foothills and lowlands in the non-breeding season, and there is evidence that similar movements are made by the Red-capped and White-crowned Manakins. In Ecuador, the Club-winged Manakin apparently makes similar elevational displacements. No other manakin is known to undertake seasonal migratory movements of any kind. Indeed, those species that have been investigated in detail have been found to be highly sedentary. For example, in a Trinidad population of White-bearded Manakins studied intensively for 3·5 years, a colour-ringed male was seen while foraging about 800 m from where it had first been trapped, and three colour-ringed females were found nesting at about the same distance from the ringing site; these were the longest movements recorded. Except for the moulting period, most adults, at least, spent the whole time within very restricted areas. During the moult, when the display grounds were largely abandoned, systematic trapping indicated that some individuals wandered farther, since a considerable proportion of adults trapped at that time were never recorded again. Trapping of Golden-headed Manakins in the same area produced similar results.



Established males at display grounds, in particular, are extremely sedentary for much of the year. Male White-bearded Manakins were recorded as spending up to 90% of the daylight hours at their courts, making only brief excursions, nearly all less than 5 minutes in duration, in order to forage at nearby fruit sources, with a slightly longer absence in the late afternoon to bathe in a stream close by. Similarly, a male Golden-headed Manakin, watched throughout the day, was present on his display perch for 88% of the time; he made brief foraging excursions and, in the afternoon, one longer one, of 5 minutes, during which he bathed. A male Pin-tailed Manakin in south-east Brazil was observed throughout the hours of daylight, and was found to be present in his display territory for 87% of the period.

These findings have been confirmed and much amplified by the results of radio-tracking experiments by Théry in French Guiana, involving five manakin species. For four species of typical piprid, the Golden-headed, White-fronted, White-crowned and White-bearded Manakins, the home ranges of adult males during the breeding season were very restricted, from 2·1 ha to 3·4 ha, and included the individual bird's display area and one bathing site. The home ranges of females were more extensive, from 8·8 ha to 14·4 ha, and contained several display areas and bathing sites, and those of immature males were larger still, from 18·7 ha to 24·1 ha. Outside the breeding season, they all used much wider areas; radio-tracking over short periods indicated ranges of 30-32 ha, and these would probably have extended to several hundred hectares if the tracking had continued for long periods.

The fifth species tracked, the Thrush-like Mourner, was found to have much larger home ranges than those of the four typical manakins during the breeding season. The figures for two males were 14·3 ha and 16·5 ha, respectively, and the home range of one female was 20·1 ha. Thrush-like Mourners are more insectivorous than the typical manakins; the males have no fixed display area but give their advertising calls while on the move, as they forage through the forest undergrowth.

Relationship with Man

The native Americans of Amazonia and other areas of humid forest could hardly fail to be familiar with many manakin spe-

*The **Black-capped Piprites** is an unusual manakin restricted to the Atlantic Forest. There are records from Minas Gerais south to Rio Grande do Sul, and it has even been seen far inland in Misiones, Argentina. However, it has always been scarce and unevenly distributed. Also, suitable habitat has been heavily fragmented, and its overall numbers must have declined. For these reasons it is classed as Vulnerable. Fortunately, it occurs at some well-protected sites, such as Itatiaia National Park, where it is fairly common.*

[*Piprites pileata*, Campos do Jordão, São Paulo, Brazil. Photo: Edson Endrigo]

cies, especially those with conspicuous displays. In Amazonian Brazil, the brightly coloured *Pipra* species are associated with a variety of legends, superstitions and witchcraft. Dried skins, as well as whole birds preserved in alcohol, are used as charms, talismans and amulets. No doubt there were many local names for the different species. The word *manaquim*, from which *Manacus* and the English vernacular "manakin" are derived, may be a transliteration of an indigenous name used in the upper Amazon.

More recently, the amazing co-operative "dancing" displays of the blue-backed *Chiroxiphia* manakins became familiar enough to the Spanish and Portuguese settlers to earn the name *bailador* for the Long-tailed Manakin and *dançador* for the Blue Manakin. In Trinidad, where the White-bearded Manakin is especially abundant and its leks, with wing-snapping birds leaping to and fro between vertical stems close to the ground, often near forest paths, can hardly be missed, it is known to country people as the "stick-man".

Status and Conservation

In many Neotropical forest areas, manakins are among the most abundant birds of the forest understorey. Thus, in three years of mist-netting in French Guiana, the area's seven species of manakin made up one third of all birds trapped, and in 3·5 years of mist-netting in Trinidad the number of manakins trapped, of two species, far exceeded the combined total for eleven species of tyrant-flycatcher of the forest understorey. The efficiency of manakins as dispersers of the main fruits on which they feed (see Food and Feeding) is probably a main reason for their general abundance. A few species, however, are unaccountably scarce or local.

Of the 58 piprid species currently recognized, four are considered to be globally threatened and a further one could potentially join that category. The species most at risk is the Araripe Manakin (*Antilophia bokermanni*), the conservation status of which is listed as Critical. This little-known species, the handsome male sporting a plumage of white, black and red, is confined to an extremely tiny range in north-east Brazil. It was first discovered as recently as 1996, in the foothills of the Chapada do Araripe, in south-east Ceará, and has not been found anywhere away from the type locality. Its known range, therefore, covers no more than about 1 km². Although there is hope that it may be present elsewhere in nearby foothills, it has not yet been found there, despite searches having been carried out in the region. The total population, of fewer than 250 individuals, lives in tall secondary forest in the Araripe National Forest, which is encompassed within a large Environmental Protection Area, but legal protection is minimal. Lowland areas adjacent to the species' habitat have already been cleared for commercial plantations, farmsteads and human settlement, and associated developments, including road-building and the construction of recreational facilities, constitute a major threat. Unless effective protection of this manakin's habitat is achieved, its future prospects appear bleak. Even in the event of additional populations of the Araripe Manakin being located in nearby forest, there is no guarantee that these could be safeguarded.

Farther south, in the lowland forests of south-east Brazil, Wied's Tyrant-manakin (*Neopelma aurifrons*) has similarly suffered from extensive loss of habitat and is now classified as Endangered. It has been found at a number of localities from Bahia south to Rio de Janeiro, but there are very few records since 1990. The species was formerly treated as conspecific with the Serra Tyrant-manakin (*Neopelma chrysolophum*), which may have obscured its true status. Nevertheless, it appears certainly to have been more widespread in the past in Bahia and Minas Gerais, in both of which states it has not been seen for some years. It was present in Chapada Diamantina National Park, in Bahia, but was last recorded there in 1990. In Espírito Santo, it was uncommon in Sooretama Biological Reserve in 1981 and

*The **Golden-crowned Manakin** is extremely poorly known. After its discovery in 1957 on the upper River Cururu-ri in Pará, Brazil, it went unrecorded until May 2002, when it was found 200 km away. Further surveys are urgently required to clarify its range and status, and to formulate an effective programme of conservation action, if required.*

[*Lepidothrix vilasboasi*, Consorcio Jamanxim, Novo Progresso, Pará, Brazil. Photo: Fabio Olmos]

*In 1996, the Chapada do Araripe played host to one of the most staggering ornithological discoveries of recent times. The **Araripe Manakin** is not a cryptic species, and only evaded detection so long because its entire global range is very small (roughly 1 km²). With a tiny population, and shrinking habitat, the species is classified as Critical. If conservation action is not implemented urgently, the prospects for its survival seem bleak.*

[*Antilophia bokermanni*, Barbalha, Chapada do Araripe, Ceará, Brazil. Photo: Edson Endrigo]

has been seen there only once since, and it occurs locally within Augusto Ruschi Biological Reserve. Otherwise, Wied's Tyrant-manakin is known from a single locality in the state of Rio de Janeiro, and one target of conservationists is to achieve full and effective protection for this forest, situated north-east of the city of Rio de Janeiro itself.

Two piprids are categorized as Vulnerable. These are the Golden-crowned Manakin (*Lepidothrix vilasboasi*) and the Black-capped Piprites (*Piprites pileata*), both of which, as the two other threatened species, are Brazilian, although the latter has been recorded once in north-east Argentina. The Golden-crowned Manakin is so little known that it is difficult to say anything definite about possible threats to its survival. It has been seen only in south-west Pará. The type locality, where the species was discovered by H. Sick in 1957, is on the upper River Cururu-ri, a tributary of the River Teles Pires. It lies within an area of 400,000 ha belonging to the Brazilian air force; here, access is limited and there is no logging. The manakin had not been seen again since its initial discovery, until, in May 2002, it was rediscovered at Consórcio Jamunxim, 200 km north-east of the type locality. This second site, however, is under pressure from an increasing human population and the planned paving of the Cuiabá-Santarém road, which traverses the region. Clearly, fieldwork is needed in order to determine the species' current status and distribution. It seems that the earlier failure of ornithologists to relocate this manakin was probably the result of some confusion over its precise type locality. There are two right-bank tributaries of the Teles Pires bearing the name Cururu. The original specimens were found on the Cururu-ri (often referred to simply as Cururu), which flows north-west, but a better-known river is the Cururu-açu, farther south, which flows south-west to join the main Teles Pires.

The other Vulnerable member of the family, the Black-capped Piprites, has apparently always been rare and local, but it has evidently become more so in recent years, especially in the south of its range, where the *Araucaria* forest in which it occurred has been extensively destroyed. It is restricted to south-east Brazil, from Minas Gerais and Rio de Janeiro south to Rio Grande do Sul, and there is a single record from extreme north-east Argentina, where an individual was caught in September 1959. Although very sparsely distributed and certainly rare, this species does occur in several protected areas in Brazil, including Itatiaia, Serra da Bocaína and Aparados da Serra National Parks and Campos do Jordão State Park. Rumours of its presence in Iguazú National Park, in Argentina, have never been substantiated. It appears to prefer montane forest, which is not at so great a risk of being cleared as are forests in the lowlands, and its prospects for survival should, therefore, be reasonably secure, at least in the short term.

In addition to these four threatened piprids, one other, the Yellow-headed Manakin (*Chloropipo flavicapilla*), is currently considered Near-threatened. This species, patchily distributed in montane forest and mature second growth in the Andes of Colombia and Ecuador, is generally uncommon to rare. There are few recent records, although it is an inconspicuous bird and may have been overlooked. Much of the range within which the Yellow-headed Manakin occurs consists of potentially good-quality agricultural land, and a good deal of its habitat has already been lost as a consequence. It is desirable that the precise status of this manakin be established by means of further fieldwork and research, and any possible changes in its circumstances should be closely monitored.

Finally, two members of the family with rather limited ranges, the Opal-crowned Manakin (*Lepidothrix iris*) of Brazil and the Grey-headed Piprites (*Piprites griseiceps*) of Central America, were formerly included in the category of Near-threatened. Both had suffered habitat loss as a result of forest clearance, but recent work suggests that there is no longer any reason for immediate concern over their conservation status.

In general, the future conservation of manakins, as that of many other Neotropical birds, will depend on the effective protection of adequate areas of forest. Because of their small size, enabling populations to be maintained within relatively small areas, and because many species occur in mature secondary woodland as well as in primary forest, the prospects for the manakins should be better than those of larger and ecologically more specialized forest birds.

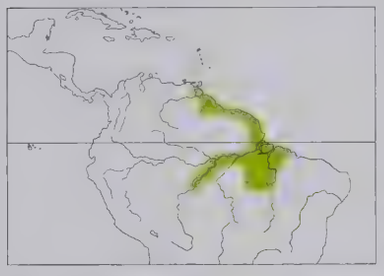
PLATE 10

inches 4

cm 10



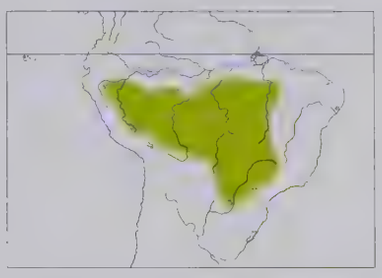
Genus *PIPRA* Linnaeus, 1764

1. Crimson-hooded Manakin

Pipra aureola

French: Manakin auréole **German**: Rothaubenpipra **Spanish**: Saltarín Cabecinaranja
Other common names: Anomalous Manakin ("*P. anomala*")

Taxonomy. [*Parus*] *Aureola* Linnaeus, 1758, "some part of South America, near the equinoctial line" = Surinam.
Closely related to, and forming a superspecies with, *P. fasciicauda* and *P. filicauda*, all three replacing each other geographically. "*P. heterocerca*" is hybrid between present species and *P. filicauda*. Has apparently hybridized also with *Heterocercus linteatus* (hybrid form described as "*Pipra anomala*"). Four subspecies recognized.
Subspecies and Distribution.
P. a. aureola (Linnaeus, 1758) - E Venezuela, the Guianas and NE Brazil.
P. a. flavicollis P. L. Sclater, 1851 - middle Amazon region of Brazil.
P. a. aurantiicollis Todd, 1925 - lower middle Amazon region in W Pará (Brazil).
P. a. borbae J. T. Zimmer, 1936 - along R Madeira, in Brazil.



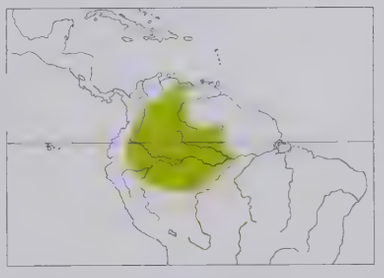
Descriptive notes. 11 cm; 14-18·5 g. Male nominate race has orange-yellow on face and throat; otherwise, foreparts to upper mantle and lower breast crimson; rest of plumage black, except for creamy to whitish thighs and some reddish or orange on vent; barbs of secondaries stiff and shafts thickened; iris white or whitish; bill blackish, paler grey below, and palest along cutting edges; legs pink or purplish-pink. Differs from *P. fasciicauda* in more extensively crimson foreparts, mainly black belly and vent, lack of white in tail. Female is dull olive-green, yellowish-tinged on lores, throat and in diffuse streaks on breast; greyer below, palest on belly; iris pale grey. Immature male resembles female, but iris dark. Races vary mainly in width and definition of yellow frontal band; *flavicollis* differs from nominate in having yellow frontal band narrow and more clearly demarcated from crown, yellow extending farther down throat; *borbae* differs from previous in yellow on forehead being much broader, extending farther back and merging with red of crown, tail shorter; *aurantiicollis* has very narrow yellow frontal band not sharply defined, rather deep yellow throat. Voice. Main call of male a plaintive, somewhat drawn-out "eeeeew", also sharper, double "chee-weep". In flight display male makes two wing noises, a soft "poop" at lowest point of flight, and a click on landing.
Habitat. Swampy and seasonally flooded forest (*várzea*), tangled woodland along watercourses, undergrowth of secondary forest, locally mangroves; also white-sand *campina* forest in Brazil (Amapá). Mostly below 300 m; at 1200 m near Cerro Roraima, in Venezuela.
Food and Feeding. Small fruits, especially of species of Araceae, also insects and spiders. Items plucked or snatched in aerial sallies from nearby perch.
Breeding. Egg-laying in Feb-Mar in Guyana, Oct and Mar-May in Surinam and Oct-May in French Guiana. Male performs complex lek display with others, with co-ordinated alternating display-flights; only dominant (older) male mates with visiting females. Nest a small open cup slung in fork of shrub, c. 1 m above ground. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Resident; dominant males sedentary.
Status and Conservation. Not globally threatened. Rather uncommon over much of range; locally abundant in Guianan coastal areas.
Bibliography. Bangs & Penard (1918), Colorado & Pulgarín (2003), Cracraft (1985), Forrester (1993), Graves (1981), Haffer (1997b, 2002), Haverschmidt (1965, 1968), Haverschmidt & Mees (1994), Hellmayr (1929), Hilty (2003), Le Maitre & Reynaud (1994), Meyer de Schauensee (1982), Novaes (1978a), Ouellet (1990), Reynaud (1998), Ridgely & Tudor (1994), Robbins (1983), Schubart *et al.* (1965), Sick (1993, 1997), Snow (1963a), Snyder (1966), Stotz *et al.* (1996), Tostain (1988b), Tostain *et al.* (1992).

2. Band-tailed Manakin

Pipra fasciicauda

French: Manakin à queue barrée **German**: Schwanzbindenpipra **Spanish**: Saltarín Naranja

Taxonomy. *Pipra fasciicauda* Hellmayr, 1906, Guarayos, Santa Cruz, Bolivia.
Closely related to, and forming a superspecies with, *P. aureola* and *P. filicauda*, all three replacing each other geographically. Five subspecies recognized.
Subspecies and Distribution.
P. f. saturata J. T. Zimmer, 1936 - tropical zone of N Peru E of Andes (in San Martín).
P. f. purusiana Snethlage, 1907 - E Peru S of Amazon (Loreto S to Cuzco) and W Brazil (Acre, and upper R Purús in Amazonas).
P. f. fasciicauda Hellmayr, 1906 - SE Peru (N Puno) and N & NE Bolivia (near Andes in Cochabamba and N Santa Cruz).
P. f. calamae Hellmayr, 1910 - WC Brazil (limited area near upper R Madeira and extreme NW Mato Grosso).
P. f. scarlatina Hellmayr, 1915 - interior Brazil from C Pará (S of Belém area) S to Mato Grosso do Sul, S Goiás, W Minas Gerais and NW São Paulo, with apparently isolated populations in NE (Ceará and Alagoas), and extreme N Bolivia (Pando, Beni), SE Paraguay and extreme NE Argentina (Misiones).
Descriptive notes. 11 cm; 11·5-19 g. Male nominate race has red forebody with some yellow admixed on breast; much yellower on face and throat, light creamy yellow on rest of underparts; rest of plumage black, except for white tail base, white patch on inner webs of flight-feathers (white wingstripe in flight); barbs of secondaries stiff and shafts thickened; iris white or nearly so; bill blackish, paler grey below, palest along cutting edges; legs dull reddish, greyer and sootier on feet. Differs from *P. aureola* in having more yellow and less red on foreparts, paler underparts, white tail base. Female is dull olive-green, tinged yellow on parts of face and breast, greyer below, belly palest, iris pale grey or magenta to whitish; almost indistinguishable from female *P. aureola*, perhaps very slightly more yellowish-green above and very slightly more yellowish on belly. Immature male resembles female, has iris brown or grey. Races vary mainly in degree of scarlet staining on breast, least developed in nominate, noticeably deeper and extending farther over plumage in *scarlatina*, deepest and most extensive (reaching to lower belly) in *saturata*. Voice. Male advertisement call a downward-inflected "eeew"; display call a somewhat harsh "wee-ee-eeh"; in flight display a prolonged "eeeooo", also two wing noises, i.e. a very low-pitched "kloop" in descending part and a sharp "klok" at end of flight.



Habitat. Seasonally flooded lowland forest (*várzea*) and gallery forest; to 600 m in Peru. Of 50 individuals mist-netted during study in S Brazil (Mato Grosso do Sul), most were in *cerradão* and gallery forest.
Food and Feeding. Small fruits (Melastomataceae, Rubiaceae) and insects. In study in S Brazil (Mato Grosso do Sul), 93% of faecal samples contained fruits or seeds and 7% insect remains. Items plucked or snatched from vegetation in flight. Has been observed to follow army ants (*Eciton burchelli*) for brief period.
Breeding. In Brazil, egg-laying in Dec in N (Belém area) and species breeds mainly Aug-Nov in S (E Mato Grosso do Sul). Male performs complex lek display with others, with co-ordinated alternating display-flights; yellow vent conspicuously exhibited in courtship; only dominant (older) male mates with visiting females. Nest a tiny cup of fungal rhizomorphs on base of dead leaves, 2-3 m up in fork of small tree. Clutch 2 eggs; no information available on incubation and fledging periods.
Movements. None reliably reported.
Status and Conservation. Not globally threatened. Fairly common to common in most of range; present in several protected areas, e.g. Chapada dos Guimarães National Park (Brazil) and Noel Kempff Mercado National Park (Bolivia). Survival of the undoubtedly small, apparently isolated populations in NE Brazil (Ceará and Alagoas) must be uncertain, in view of deforestation and desiccation of that region; occurs in Serra do Baturité State Environmental Protection Area, in Ceará.
Bibliography. Allen (1995), Angehr & Aucca (1997), Bates & Parker (1998), Brooks *et al.* (1993), Canevari *et al.* (1991), Capper *et al.* (2000), Chebez (1994), Chebez *et al.* (1999), Davis (1993), Dubs (1992), Foster (1985), Fraga & Narosky (1985), Graves (1981), Haffer (1971, 1997b, 2002), Hayes (1995), Hellmayr (1929), Lowen *et al.* (1996), Mazar Barnett & Pearman (2001), Mello & Piratelli (1997), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Oniki & Willis (1983a), Oren & Parker (1997), de la Peña (1989), Pichorim *et al.* (2000), Piratelli & Mello (2001), Ridgely & Tudor (1994), Robbins (1983, 1985), Robinson & Terborgh (1997), Saibene *et al.* (1996), Schulenberg *et al.* (2001), Sick (1960, 1993, 1997), de Souza (2000), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984).

3. Wire-tailed Manakin

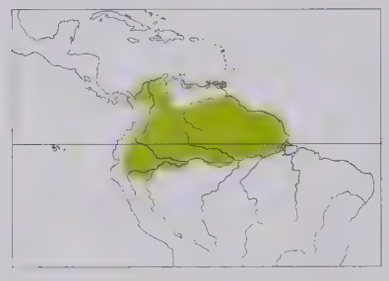
Pipra filicauda

French: Manakin filifère **German**: Fadenpipra **Spanish**: Saltarín Uirapuru

Taxonomy. *Pipra filicauda* Spix, 1825, São Paulo de Olivença, River Solimões, west Amazonas, Brazil.
Was for long placed in monotypic genus *Teleonema* on basis of highly modified tail feathers. Closely related to, and forming a superspecies with, *P. aureola* and *P. fasciicauda*, all three replacing each other geographically. "*P. heterocerca*" is hybrid between present species and *P. aureola*. Race *subpallida* apparently intergrades with nominate around Colombia-Ecuador border. Two subspecies recognized.
Subspecies and Distribution.
P. f. subpallida (Todd, 1928) - E Colombia (E of Andes) and NW Venezuela (E, on both sides of Andes, to Miranda).
P. f. filicauda Spix, 1825 - S Venezuela (S & W Amazonas), NW & C Brazil (E to mouth of R Negro, S to headwaters of R Juruá and middle R Purus), E Ecuador and NE Peru (S to middle R Ucayali).

Descriptive notes. 11·5 cm, exclusive of tail filaments (which c. 4 cm long on male, 2·5 cm on female); mean 13·9 g. Male has yellow forecrown, face and underparts, bright red crown to upper mantle and side of neck; rest of upperparts, including wings and tail, black; secondaries with barbs stiffened and shafts thickened, rectrices with long curved filaments; underwing-coverts black; iris white or nearly so; bill blackish, paler along cutting edges; legs sooty reddish. Female is dull olive-green, tinged yellow on face and breast, greyer below, belly palest; very similar to female *P. fasciicauda*, but larger, has tail filaments, and is slightly brighter yellow on throat and belly. Immature resembles female, but has brown iris; at more advanced stage of immature plumage, male has brighter yellow underparts, yellowish frontal band, white iris. Race *subpallida* is very like nominate but slightly paler. Voice. Male advertisement call a downward-inflected "eeew". Two wing noises in courtship: a very low-pitched "kloop" in descending part of display-flight and a sharp "klok" at end of flight.

On following pages: 4. Golden-headed Manakin (*Pipra erythrocephala*); 5. Red-headed Manakin (*Pipra rubrocapilla*); 6. Red-capped Manakin (*Pipra mentalis*); 7. Round-tailed Manakin (*Pipra chloromeros*); 8. Scarlet-horned Manakin (*Pipra cornuta*).



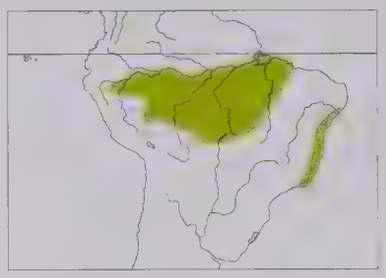
Habitat. Gallery forest, second growth, and lighter open woodlands, including cocoa plantations in Venezuela; in all habitats often near streams. Mostly below 300 m, but to 500 m in Peru and 750 m in Ecuador; to 1000 m N of R Orinoco (Venezuela).
Food and Feeding. Small fruits and insects. Food items plucked or snatched in flight.
Breeding. Nesting in progress in May-Jun in N Venezuela. Male performs complex lek display with others, with co-ordinated alternating display-flights; elongated tail filaments used as tactile organs in courtship; only dominant (older) male mates with visiting females. Nest a small cup slung in horizontal fork of small tree or shrub, mainly 2-4 m above ground, frequently in vegetation bordering or overhanging a stream. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Locally common in suitable habitat. Despite fairly wide habitat tolerance, is patchily distributed in N Venezuela, but occurs there in Henri Pittier and Guatopo National Parks. Elsewhere present in several protected areas, e.g. Amacayacu National Park (Colombia) and Cuyabeno Reserve (Ecuador).
Bibliography. Best *et al.* (1997), Butler (1979), Friedmann (1948), Graves (1981, 1993), Haffer (1997b, 2002), Heindl (2002), Heindl & Winkler (2002, 2003a, 2003b), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Iafrancesco *et al.* (1987), Meyer de Schauensee (1982), Ortiz & Carrión (1991), Pearson & Belebsky (2000), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robbins (1983), Schubart *et al.* (1965), Schwartz & Snow (1979), Sick (1993, 1997), Snow (1975a), Stotz *et al.* (1996).

4. Golden-headed Manakin

Pipra erythrocephala

French: Manakin à tête d'or **German**: Gelbkopfpipra **Spanish**: Saltarín Cabecidorado
Other common names: Yellow-thighed Manakin

Taxonomy. [*Parus*] *erythrocephalus* Linnaeus, 1758, Surinam.
May form a superspecies with *P. rubrocapilla* and *P. mentalis*; has been considered conspecific with former, but the two occur sympatrically in NE Peru (along R Ucayali and lower R Huallaga). Birds from E Colombia sometimes separated as race *flammiceps*, but considered indistinguishable from *berlepschi*. Two subspecies recognized.
Subspecies and Distribution.
P. e. erythrocephala (Linnaeus, 1758) - E Panama, NW, NC & NE Colombia, Venezuela, Trinidad, the Guianas, and N Brazil (N of middle and lower Amazon).
P. e. berlepschi Ridgway, 1906 - S & E Colombia, E Ecuador, NC & NE Peru, and NW Brazil (N of upper Amazon).



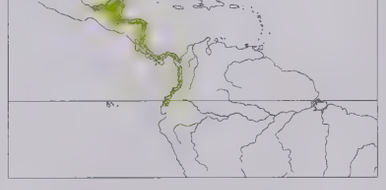
Descriptive notes. 8-9 cm; male average 12·8 g (Trinidad), 11·1 g (Surinam) and 11·8 g (French Guiana), female average 14·1 g (Trinidad), 12·5 g (Surinam) and 12·6 g (French Guiana). Male nominate race has orange-yellow head from forehead and malar area to hindneck, yellow very indistinctly outlined in red; rest of plumage black, except for red and white thigh feathers; iris white; bill pale yellowish to greyish-white; legs brownish flesh. Female is dull olive-green, paler below, especially on belly, which has slight yellowish wash; iris usually grey, sometimes with variable amount of white. Juvenile resembles female, but eyes grey; young male often acquires some adult feathers in first moult (after a few months), at next moult gains full adult plumage. Race *berlepschi* has yellower crown, with narrower and more sharply defined red border, than nominate. Voice. Main call of male on display-perch 3-4 syllables, a clear note followed by trill, ending in one or two sharp notes, "pu prrrrrr-pt(pt)"; also short, sharp "zit, zit". In display-flight to perch, accelerating series of "kew" notes, followed by sharp buzz on landing.
Habitat. Forest and secondary woodland, both humid and partly deciduous; mostly low to middle altitudes, locally to 2000 m.
Food and Feeding. Small fruits and arthropods. In 4-year study in small area of forest in Trinidad, fruits of 43 plant species recorded as taken, by far the most important being the small berries of the melastomataceous genus *Miconia*; in French Guiana Melastomataceae also most important plant family, followed by Rubiaceae. Fruits plucked in flight, swallowed on landing. Small insects and spiders snatched in flight from twigs and foliage.
Breeding. Egg-laying in Jan-Aug, mostly Mar-Jul (end of dry season and beginning of wet season), in Trinidad; from Nov (at start of rains) in Surinam, and in Mar-Jul (during main rainy season) in French Guiana. Male has complex lek display with others, each on separate perch, posture and movements highly stereotyped and diverse, consisting of five elements, including rapid flights with "about-face" on landing; red and white thigh feathers exhibited conspicuously. Nest a small shallow cup thinly woven from vegetable fibres, dead leaf petioles and rootlets, lined with black fungal strands (*Marasmius*), often with few dead leaves attached to sides of cup and hanging from underside, attached by cobweb, slung in fork between horizontal twigs of sapling, shrub or lower branches of tree, 1·5-10 m above ground. Clutch 2 eggs; incubation 16-17 days; fledging period not documented. Nesting success evidently low; of seven nests found in Trinidad during laying or incubation, none survived to fledging stage.
Movements. Resident. In radio-tracking study in French Guiana, adults sedentary when breeding, moving over larger area (probably of several hundred hectares) during moult period; an immature male wandered over range of 22·7 ha.
Status and Conservation. Not globally threatened. Fairly common to common generally; in many areas one of the most abundant of all forest bird species. In 100-ha Trinidad study area, total of 625 individuals trapped over period of 3 years and 3 months. In French Guiana during breeding season, home ranges of two adult males were 3 ha and 3·4 ha (centred on single display area and bathing site), and of two females 12·8 ha and 14·4 ha (including several male display areas and bathing sites). Present in numerous protected areas, e.g. Darién National Park (Panama), Guatopo National Park (Venezuela) and Asa Wright Nature Centre (Trinidad).
Bibliography. Allen (1961), Bangs & Penard (1918), Best *et al.* (1997), Blake (1950, 1962), Bond *et al.* (1989), Borgia *et al.* (1985), Butler (1979), Canaday & Jost (1997), Capparella (1988), Cohn-Haft *et al.* (1997), Eisenmann (1955), ffrench (1991), Friedmann (1948), Gilliard (1941), Graves (1981), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Heindl & Winkler (2002, 2003a), Hellmayr (1929), Herklots (1961), Hilty (2003), Hilty & Brown (1986), Hudon *et al.* (1989), Iafrancesco *et al.* (1987), Lill (1976), Meyer de Schauensee (1982), Murphy (1995), Ortiz & Carrión (1991), Ouellet (1990), Reynaud (1998), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Schubart *et al.* (1965), Schulenberg *et al.* (2001), Sick (1960, 1993, 1997), Snow (1962b), Snyder (1966), Stotz *et al.* (1996), Théry (1990b, 1990c, 1992, 1997), Tostain *et al.* (1992), Wetmore (1972), Willard *et al.* (1991), Zimmer & Hilty (1997).

5. Red-headed Manakin

Pipra rubrocapilla

French: Manakin à tête rouge **German**: Rotkopfpipra **Spanish**: Saltarín Cabeirrojo Sureño

Taxonomy. *Pipra rubro-capilla* Temminck, 1821, Bahia, Brazil.
May form a superspecies with *P. erythrocephala* and *P. mentalis*; has been considered conspecific with former, but the two occur sympatrically in NE Peru (along R Ucayali and lower R Huallaga). Monotypic.
Distribution. E Peru, Brazil S of Amazon (E to N Maranhão, S to Rondônia and SC Mato Grosso, also disjunct coastal population from Pernambuco S to Rio de Janeiro) and N Bolivia.



Descriptive notes. 10 cm; male 10·9-13·8 g, female 12·7-16·6 g. Male has red head from forehead and malar area to hindneck, red thighs; rest of plumage black; iris hazel-brown; bill pale brownish; legs dull pinkish. Differs from *P. erythrocephala* in head colour and eye colour, also longer tail; from *P. mentalis* in red thighs, black underwing-coverts. Female is dull olive-green, paler below, especially on belly, iris and bill darker than male's; very similar to female *P. erythrocephala*, perhaps very slightly more yellowish on throat and belly. Juvenile plumage not documented, presumed similar to female. Voice. Main call of male "drree-dit, dree-dee-dew", with variations; other calls include sharp "zit, zit" and in display-flight series of "kew" notes, similar to calls of *P. erythrocephala*.
Habitat. Humid lowland forest and secondary woodland; to 500 m.
Food and Feeding. Small fruits and insects, plucked or snatched in flight.
Breeding. Eggs laid in Sept-Apr in N Brazil (Belém area). Male has complex lek display with others, posture and movements highly stereotyped and diverse, consisting of several elements, including rapid flights with "about-face" on landing; red thigh feathers exhibited conspicuously. Nest 2-5 m above ground. Clutch 2 eggs; incubation period not documented; fledging period 13-14 days.
Movements. No information; almost certainly sedentary.
Status and Conservation. Not globally threatened. Fairly common to common in most of range. Isolated E Brazilian population much reduced by extensive destruction of lowland forest; occurs in Pedra Talhada State Park and in Sooretama Biological Reserve.
Bibliography. Acheson & Davis (2001), Allen (1995), Bates & Parker (1998), Capparella (1988), Castro Astor, Alves & Cavalcanti (2004), Castro Astor, Cavalcanti & Alves (1998), Dubs (1992), Graves (1981), Gyldenstolpe (1950), Hellmayr (1929), Hudon *et al.* (1989), Meyer de Schauensee (1982), Oren & Parker (1997), Parker, Donahue & Schulenberg (1994), Pinto (1953), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1967, 1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tobias *et al.* (1993), Zimmer *et al.* (1997).

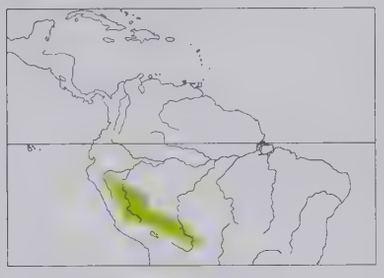
6. Red-capped Manakin

Pipra mentalis

French: Manakin à cuisses jaunes **Spanish**: Saltarín Cabeirrojo Norteño
German: Nördliche Gelbhosenpipra
Other common names: Yellow-thighed Manakin

Taxonomy. *Pipra mentalis* P. L. Sclater, 1857, Córdoba, Veracruz, Mexico.
May form a superspecies with *P. erythrocephala* and *P. rubrocapilla*. Three subspecies recognized.
Subspecies and Distribution.
P. m. mentalis P. L. Sclater, 1857 - from SE Mexico (S Veracruz) S, on Caribbean slope, to E Costa Rica.
P. m. ignifera Bangs, 1901 - Panama, mainly on Caribbean side.
P. m. minor Hartert, 1898 - W Colombia and W Ecuador.

Descriptive notes. 10 cm; 12·5-18·5 g. Male has red head from forehead and malar area to hindneck, creamy yellow thighs; rest of plumage mostly black; secondaries enlarged, curved and stiffened, with thick shafts; underwing-coverts yellow; iris white; bill brownish, darker and greyer above, paler horn below; legs dull reddish to lead-grey. Differs from very similar *P. rubrocapilla* in yellow thighs and yellow underwing-coverts. Female is dull olive-green, paler below, especially on belly, iris dull brown or, rarely, white; very similar to female *P. rubrocapilla* but perhaps very slightly duller below. Immature is like adult female; immature male at advanced stage has white iris and usually some adult feathers on head and body. Race *ignifera* male has red and yellow colours deeper and black more intense than nominate; *minor* is smaller. Voice. Main call of male a short, explosive "psip", often preceded by high, thin "p'tsweeeeee"; full call in display "psit psit psit p'tsweeee psip", final note sharp and emphatic. Display also accompanied by wing-snaps.
Habitat. Humid forest and mature secondary woodland, mostly below 500 m; to 750 m in Mexico.
Food and Feeding. Chiefly small fruits and insects, taken in rapid aerial sally. Sometimes joins mixed-species parties following army ants.
Breeding. Eggs laid in Mar-Jun in Costa Rica, Feb-Jul in Panama. Male has complex lek display with others, posture and movements highly stereotyped and diverse, consisting of several elements, including rapid flights with "about-face" on landing; yellow thighs and underwing-coverts exhibited conspicuously. Nest a small cup mainly of vegetable fibres, sometimes with black fungal filaments as lining, and variable number of leaf fragments hanging below, suspended c. 1·5-9 m above ground in horizontal fork of shrub, sapling or small tree, bound to supporting arms by cobweb. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Generally sedentary. In Costa Rica, probably some regular movement to lower altitudes in non-breeding season; no other information.



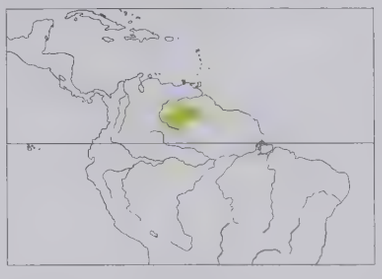
Status and Conservation. Not globally threatened. Common to fairly common where lowland forest remains; often rather local in occurrence. Numbers in W Ecuador have declined severely as a result of extensive deforestation in lowlands, but species is still very common in NW.
Bibliography. Bangs (1903), Bartholomew *et al.* (1983), Best *et al.* (1997), Binford (1989), Blake & Loiselle (2002), Bostwick & Prum (2003), Brodkorb (1943), Butler (1979), Cracraft (1985), Dearborn (1907), Eisenmann (1955), González-García (1993), Graves (1981), Griscom (1950), Haffer (1975), Hellmayr (1929), Herrera-Rosales (1998), Hilty & Brown (1986), Howell & Webb (1995a), Hudon *et al.* (1989), Klaas (1968), Komar & Domínguez (2001), Land (1970), Lee Jones (2004), Levey (1987), Loiselle & Blake (1999), Meyer de Schauensee (1982), Miller (1995), Moermond & Denslow (1985), Monroe (1968), Ortiz & Carrión (1991), Paynter (1955, 1957), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Rutgers & Norris (1977), Selvin & Castillo (2000), Skutch (1967, 1969), Slud (1960, 1964), Smithe (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Van Tyne (1935), Westcott (1994), Wetmore (1972), Willis & Eisenmann (1979), Worthington (1982a, 1982b, 1983, 1989).

7. Round-tailed Manakin

Pipra chloromeros

French: Manakin à queue ronde **Spanish**: Saltarín Coliancho
German: Südliche Gelbhosenpipra

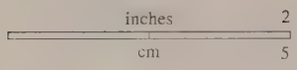
Taxonomy. *P[ipra] chloromeros* Tschudi, 1844, Vitoc Valley, Junín, Peru.
Monotypic.
Distribution. E Peru (S from S Amazonas and San Martín), adjacent W Brazil (Acre) and N Bolivia.



Descriptive notes. 11 cm; 16·5 g. Male has red from forehead and malar area to hindneck, creamy yellow thighs; rest of plumage black; secondaries enlarged, curved and stiffened, with thick shafts; iris white; bill blackish, darker grey on culmen; legs smoky flesh-coloured. Distinguished from very similar *P. mentalis* by black (not yellow) underwing-coverts, rounded tail (not more or less square-cut as in congeners), red nape feathers often somewhat protruding. Female is dull olive-green, paler below, especially on belly, iris greyish; differs from female *P. mentalis* in having rounded tail. Immature is similar to adult female, but iris darker grey. Voice. Full advertisement call of male a multisyllabic "fui-ii-ii-i chi-awaaak", lasting c. 1·7 seconds, most often only second part given; display call a trisyllablic "fi-cuac-cuac", last two elements with buzzing quality, display also accompanied by double wing-snaps.
Habitat. Humid forest, from lowlands to well into Andean foothills; to 1400 m.
Food and Feeding. Few details; diet and foraging behaviour presumably similar to those of congeners.
Breeding. Mainly Aug-Nov in SE Peru. Male displays with others at "exploded" lek, defends territory with diameter of 20-50 m; display elements include, among others, to-and-fro flights between main perch and adjacent ones, rapid "about-face" turns on perch, backward slides, down-and-up swooping flights, various postures, conspicuous exhibiting of yellow thighs. Nest and eggs not documented.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common in quite extensive range, where much forest remains. Present in Tambopata-Candamo Reserved Zone, and in Manu National Park and Biosphere Reserve (Peru).
Bibliography. Allen (1995), Angehr & Aucca (1997), Chapman (1921), Cracraft (1985), Graves (1981), Graves *et al.* (1983), Hellmayr (1929), Hudon *et al.* (1989), Meyer de Schauensee (1982), Parker & Wust (1994), Parker, Donahue & Schulenberg (1994), Parker, Kratter & Wust (1994), Parker, Schulenberg & Wust (1994), Pearson & Beletsky (2001), Perry *et al.* (1997), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Stotz *et al.* (1996), Tello (2001), Terborgh *et al.* (1984), Whittaker & Oren (1999), Zimmer (1930).

8. Scarlet-horned Manakin

Pipra cornuta



French: Manakin à cornes rouges **German**: Rotschopfpipra **Spanish**: Saltarín Copetón

Taxonomy. *Pipra cornuta* Spix, 1825, "in sylvis flum. Amazonum"; error = Mount Roraima, Venezuela.
Monotypic.
Distribution. Mountains of S Venezuela and adjacent W Guyana (E to Merumé and Potaro Plateau) and extreme N Brazil (upper R Branco).

Descriptive notes. 12·5 cm; 4 adult males average 23·5 g. The largest *Pipra* species, with longer tail than congeners. Male has entire head, including chin and throat, red, feathers of hindcrown elongated to form two slightly upward-curving "horns"; thighs red, rest of plumage black; secondaries enlarged, curved and stiffened, with thick shafts; iris white; bill pale flesh; legs fleshy-coloured or brownish. Female is dull olive-green, paler below, especially on belly, slightly elongated hindcrown feathers giving tufted appearance, iris darker than male's, bill browner. Immature resembles female, eyes dark. Voice. Main advertisement call of male an abrupt trisyllabic "wrrt pit-arrk", lasting c. 1 second; less frequently a double "kerzeek". Explosive wing noise, "prrt", accompanies display.
Habitat. Humid forest and well-grown secondary woodland in highlands, at 500-1800 m.
Food and Feeding. Little information; fruits of Melastomataceae recorded as eaten. Fruits taken in sallying and hovering flights.
Breeding. Not recorded. Male has complex lek display with others, posture and movements stereotyped and diverse, consisting of several elements, including rapid flights with "about-face" on landing, backward "slides" on perch, tail-flicking; red thigh feathers exhibited conspicuously when legs fully stretched.
Movements. Resident; almost certainly sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Locally fairly common to common. Much suitable habitat remains within its range, and in many areas forest is still effectively inaccessible to major human intrusions. Present in Canaíma National Park (Venezuela).
Bibliography. Barnett *et al.* (2002), Chapman (1931), Gilliard (1941), Hellmayr (1929), Hilty (2003), Mayr & Phelps (1967), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Rodner *et al.* (2000), Snow, D.W. (1977a), Snyder (1966), Stotz *et al.* (1996), Willard *et al.* (1991).

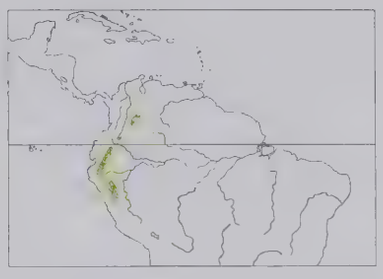
9. Blue-crowned Manakin

Lepidothrix coronata

French: Manakin à tête bleue **German**: Blauscheitelpipra **Spanish**: Saltarín Coroniazul
Other common names: Exquisite Manakin ("*exquisita* group"); Velvety Manakin (*velutina* and *minuscula*)

Taxonomy. *Pipra coronata* Spix, 1825, São Paulo de Olivença, River Solimões, west Amazonas, Brazil.
Genus often merged with *Pipra*. Taxonomy complex and poorly understood: NW populations (*velutina*, *minuscula*) may represent a separate species; populations E of Andes of two distinct types, with males black-bodied in N (*carbonata*, *caquetae*, nominate) and green-bodied in S (*exquisita*, *caelestipileata*, *regalis*), and apparently intermediate populations in W Amazonia (S of Amazon in N Peru and W Brazil). Further research needed. Eight subspecies recognized.
Subspecies and Distribution.
L. c. velutina (Berlepsch, 1883) - Costa Rica (Pacific side, also on Atlantic side in extreme E) and W Panama.
L. c. minuscula (Todd, 1919) - E Panama (E from Canal Zone), NW & NC Colombia (in E, S possibly to S Caldas) and NW Ecuador.
L. c. caquetae (Meyer de Schauensee, 1953) - S Colombia E of Andes (W Meta, W Caquetá).
L. c. carbonata (Todd, 1925) - SC & SE Colombia, S Venezuela, and NE Peru and NW Brazil N of Amazon.
L. c. coronata (Spix, 1825) - E Ecuador, and NE Peru and adjacent extreme W Brazil S of Amazon.
L. c. exquisita (Hellmayr, 1905) - C Peru E of Andes.
L. c. caelestipileata (Goeldi, 1905) - SE Peru and adjacent W Brazil.
L. c. regalis (Bond & Meyer de Schauensee, 1940) - NC Bolivia (Cochabamba).



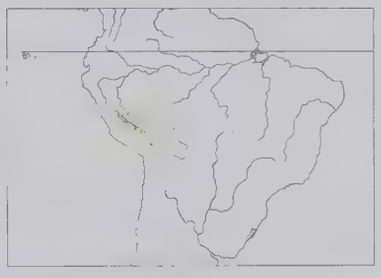
Descriptive notes. 8-9 cm; 8·5 g. Male nominate race has bright blue cap; rest of plumage entirely sooty black; iris rather dark brown-red; bill blackish above, paler grey below; legs greyish. Female is green above, duller green on breast, paler greyish on face and abdomen, the latter slightly tinged yellowish. Juvenile resembles female; immature male has blue crown, sometimes some black feathers in body plumage. Races differ mainly in male plumage coloration or intensity of colour: *caquetae* resembles nominate; *carbonata* differs in having lower belly and undertail-coverts tinged greenish-blue; *velutina* is a deeper and more lustrous black; *minuscula* resembles previous but smaller, with crown deeper blue; *exquisita* is very different, has crown paler blue, black lores, mostly black flight-feathers and tail, green upperparts, throat and chest, pale yellow central breast and belly, white vent; *regalis* differs from last in deeper blue (less silvery) crown, yellower upperparts, duller and less extensive yellow below; *caelestipileata* resembles previous but crown brighter. Voice. Male advertisement call varies geographically, including the following: a soft "tho-wiik" or "chí-wrrr", first note hiccup-like, often preceded by thin high-pitched "wheeeeee"; also a clear trill, "prrrreew"; in courtship "pi pipipipi chu-wáák", last notes nasal and frog-like; at least in Middle America (*velutina*) a musical trill, "treereereereu", by both sexes.
Habitat. Humid forest and mature secondary woodland; to 1400 m, mostly below 1000 m.
Food and Feeding. Largely small fruits; also insects. Items plucked from foliage or twigs in flight. Often joins mixed-species foraging parties.
Breeding. Eggs laid in Feb-Jun (mainly Mar-May) in Costa Rica. Male displays solitarily or at "exploded" lek, from several low slender branches, executes rapid flight manoeuvres. Following details all from Costa Rica. Nest a small cup, attached to support and bound together with cobweb, mainly of fine fibres, bottom more or less covered with dry fragments of leaf and green moss, often some hanging below, mostly 0·6-1·5 m above ground in fork of slender horizontal branch. Clutch 2 eggs; incubation period 17·5 and 19 days (two records); fledging period 13-15 days.
Movements. Little information; probably sedentary.
Status and Conservation. Not globally threatened. Locally common in most of range; fairly common to common in Ecuador and Peru. Easily overlooked.
Bibliography. Capparella (1988), Chapman (1917c), Eisenmann (1955), Graves (1981), Gyldenstolpe (1950), Haffer (1975), Heindl & Winkler (2003a), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Iafrancesco *et al.* (1987), Prum (1988), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Robinson & Terborgh (1997), Sekercioglu *et al.* (2002), Sick (1993, 1997), Skutch (1969), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz (1993), Stotz *et al.* (1996), Westcott (1994), Wetmore (1972), Zimmer (1930).

10. Blue-rumped Manakin

Lepidothrix isidorei

French: Manakin à dos bleu **German**: Blaubürzelpipra **Spanish**: Saltarín Lomiazul

Taxonomy. *Pipra isidorei* P. L. Sclater, 1852, "Nouvelle-Grenade" [Bogotá] = Buenavista, above Villavicencio, Meta, Colombia.
Genus often merged with *Pipra*. Forms a superspecies with *L. coeruleocapilla*, which it replaces geographically. Race *leucopygia* may be a separate species. Two subspecies currently recognized.
Subspecies and Distribution.
L. i. isidorei (P. L. Sclater, 1852) - E side of E Andes in Colombia (Boyacá, Meta, Cauca) and E Ecuador.
L. i. leucopygia (Hellmayr, 1903) - N Peru on E side of C Andes (San Martín, N Huánuco).



Descriptive notes. 7·5 cm. Male nominate race has shiny white cap, azure-blue rump and uppertail-coverts; rest of plumage black; iris dark brownish-red; bill blackish above, paler grey below; legs greyish. Female is green above, brightest on rump, contrasting with dusky tail, duller green on breast, with pale yellowish-grey face, grey throat and yellowish-grey abdomen; distinguished from extremely similar female *L. coronata* mainly by slightly brighter face, contrasting rump and tail. Juvenile plumage not documented, presumably like female. Race *leucopygia* differs from nominate in having rump and uppertail-coverts milky white, tinged blue at upper and lower edges. Voice. Male display call a rising "kooooit" or "wreee", repeated at intervals of 2-5 seconds.
Habitat. Humid forest in Andean foothills; 500-1700 m.
Food and Feeding. No data; presumed similar to *L. coronata*.
Breeding. Not recorded. Display little known; a solitary male in Ecuador, perched 4-8 m up on thin horizontal branches, seen to raise pale feathers of crown and rump while crouching forwards.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Locally fairly common to uncommon; rare in Peru. Observed less frequently than e.g. *L. coronata*, and seems to call less often; may be somewhat more numerous than it appears to be. In Ecuador, possibly commonest in R Bombuscaro sector of Podocarpus National Park.
Bibliography. Best *et al.* (1997), Bloch *et al.* (1991), Butler (1979), Chapman (1917c), Graves (1981), Hellmayr (1929), Hilty & Brown (1986), Iafrancesco *et al.* (1987), Mazar Barnett & Kirwan (1998b), Meyer de Schauensee (1982), Parker *et al.* (1982), Prum (1988), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996).

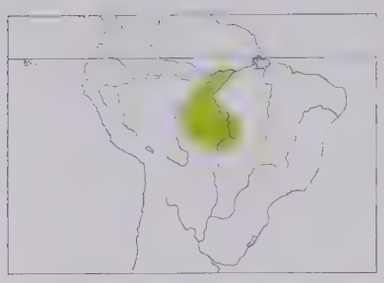
11. Cerulean-capped Manakin

Lepidothrix coeruleocapilla

French: Manakin céruléen **German**: Blaukappenpipra **Spanish**: Saltarín Coroniceleste

Taxonomy. *P[ipra] coeruleo-capilla* Tschudi, 1844, Montañas de Vitoc, Junín, Peru.
Genus often merged with *Pipra*. Forms a superspecies with *L. isidorei*, which it replaces geographically. Monotypic.
Distribution. Upper tropical zone on E slope of Andes of C & SE Peru (S Huánuco S to Puno).

Descriptive notes. 8·5 cm; 9·1 g. Male has bright blue cap, deeper blue rump and uppertail-coverts; rest of plumage black; iris dark brownish-red; bill blackish above, paler grey below; legs greyish. Female is green above, brightest on rump, tail more dusky, duller green on breast, with pale greyish face and throat, yellowish-grey abdomen; distinguished from extremely similar female *L. isidorei* by slightly larger size and longer tail. Juvenile plumage not documented; immature male has small blue spots on crown. Voice. Call a sharp "tee-zeek".
Habitat. Humid forest in foothills, also ridgetop scrub; 500-2100 m.
Food and Feeding. No information; presumably as for *L. coronata*. Occasionally observed at fruiting trees near forest edge.
Breeding. Not recorded.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Peruvian East Andean Foothills EBA. Uncommon to locally quite common. Very poorly known, and often extremely inconspicuous.
Bibliography. Clements & Shany (2001), Cracraft (1985), Mee *et al.* (2002), Meyer de Schauensee (1982), Parker *et al.* (1982), Prum (1988), Ridgely & Tudor (1994), Stotz *et al.* (1996), Walker (2001).



12. Snow-capped Manakin

Lepidothrix nattereri

French: Manakin neigeux **German**: Weißbürzelpipra **Spanish**: Saltarín Coronialbo

Taxonomy. *Pipra nattereri* P. L. Sclater, 1865, Borba, River Madeira, Brazil.
Genus often merged with *Pipra*. Probably a close relative of *L. vilasboasi*. Two subspecies recognized.
Subspecies and Distribution.
L. n. nattereri (P. L. Sclater, 1865) - C Brazil S of middle Amazon (from R Madeira, S to Calama, E to R Tapajós and its affluents).
L. n. gracilis (Hellmayr, 1903) - SC Brazil from upper R Madeira (S of Calama) E to C Mato Grosso (E to upper R Xingu drainage), S to extreme NE Bolivia (NE Santa Cruz).
Descriptive notes. Male 8·5 cm, 8 g; female 9·2 cm, 8·8 g. Male is green above, with contrasting white cap and white lower back to uppertail-coverts; flight-feathers and tail blackish with broad green edgings; chin to breast green, slightly paler and duller than back, belly to undertail-coverts yellow; iris yellowish-white or pale yellow; bill pale bluish; legs pinkish-flesh. Female nominate race is larger than male, has blue crown, green (not white) lower back to uppertail-coverts. Juvenile resembles female, but iris dark; immature male has some white feathers on crown. Race *gracilis* male is like nominate; female differs from nominate in having green crown concolorous with back. Voice. Male call a soft, short "chí-wrrr", very like call of *L. coronata*; more piercing call, a rising "pweeee", also heard given by female or juvenile individual.
Habitat. Humid forest, mainly *terra firme*; to c. 500 m.

On following page: 13. Golden-crowned Manakin (*Lepidothrix vilasboasi*); 14. Opal-crowned Manakin (*Lepidothrix iris*); 15. Orange-bellied Manakin (*Lepidothrix suavissima*); 16. White-fronted Manakin (*Lepidothrix serena*).

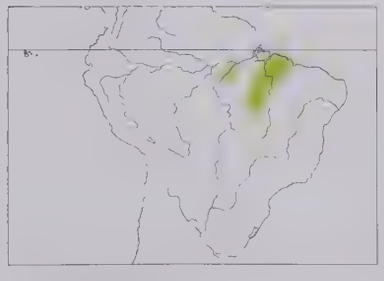
Food and Feeding. Small insects and a spider recorded in stomach contents; probably also takes small fruits.
Breeding. Not recorded.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Locally common to uncommon. Poorly known species; known to occur in Amazônia (Tapajós) National Park, in Brazil, and Noel Kempff Mercado National Park, in Bolivia.
Bibliography. Acheson & Davis (2001), Bates & Parker (1998), Dubs (1992), Forrester (1993), Haffer (1997b), Hellmayr (1929), Hennessey, Herzog & Sagot (2003), Meyer de Schauensee (1982), Oren & Parker (1997), Prum (1988), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Zimmer *et al.* (1997).

13. Golden-crowned Manakin

Lepidothrix vilasboasi

French: Manakin doré **German**: Gelbscheitelpipra **Spanish**: Saltarín Coronidorado
Other common names: Sick's Manakin ("*L. obscura*")

Taxonomy. *Pipra vilasboasi* Sick, 1959, headwaters of River Cururu-ri, south-west Pará, Brazil.
Genus often merged with *Pipra*. Probably a close relative of *L. nattereri*. Was for some time thought to be possibly a hybrid between that species (which replaces it to W) and *L. iris* (to E), but distinctive plumage characters, coupled with its recent rediscovery c. 200 km NE of type locality, leave little doubt that it is a distinct species. Described taxon *L. obscura* based on two specimens, now believed probably to be female and immature male of present species. Monotypic.
Distribution. SW Pará (upper R Cururu-ri and Consórcio Jamunxim), in C Brazil.



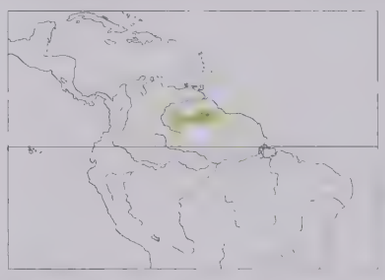
Descriptive notes. 8·5 cm. Male has glittering greenish-gold crown and nape, yellow-green lower back to uppertail-coverts; rest of head and upperparts green, flight-feathers and tail mostly blackish, broadly edged green; chin to breast green, belly to undertail-coverts yellow; iris pale greyish; bill pale bluish; legs pinkish-flesh. Presumed female has golden and yellow colours of upperside replaced by green. Juvenile plumage not documented; presumed immature male like female, but has some greenish-gold on crown. Voice. Male call a burry "prreee", sometimes in series.
Habitat. Humid forest; c. 200 m.
Food and Feeding. Small fruits and insects.
Breeding. Not recorded.
Movements. No information.
Status and Conservation. VULNERABLE. Recorded at only two sites. Until recently known only from type locality, on upper R Cururu-ri (a tributary of R Teles Pires), where not seen since time of discovery, in 1957; in May 2002, however, several individuals were found 200 km NE of there, at Consórcio Jamunxim. Earlier failure of ornithologists to relocate this manakin was probably result of confusion over precise locality (original specimens were found on R Cururu-ri, which flows NW, but a better-known river is the SW-flowing Cururu-açu, farther S). Full range of species unknown, but certainly not very large. Type locality lies within the 400,000-ha Mundurucânia Forest Reserve belonging to the Brazilian air force; here, access is limited and there is no logging. Consórcio Jamunxim is under pressure from increasing human population, as well as from planned paving of Cuiabá-Santarém road, which traverses the region. Fieldwork urgently required with the aim of determining the species' current status and distribution, and the extent of habitat destruction and further threats at its two known sites.
Bibliography. Collar & Andrew (1988), Collar *et al.* (1992), Cracraft (1985), Dinerstein *et al.* (1995), Fernández (2003), Forrester (1993), Haffer (1997a, 1997b), Meyer de Schauensee (1982), Olmos & Pacheco (2002, 2003), Parr (2002), Parrini *et al.* (1999), Prum (1988), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1959, 1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996).

14. Opal-crowned Manakin

Lepidothrix iris

French: Manakin à tête d'opale **German**: Opalscheitelpipra **Spanish**: Saltarín Opalescente
Other common names: Pearl-headed Manakin

Taxonomy. *Pipra iris* Schinz, 1851, "Guyana"; error = Belém, Pará, Brazil.
Genus often merged with *Pipra*. Two subspecies recognized.
Subspecies and Distribution.
L. i. eucephala (Todd, 1928) - SW Pará (right bank of lower R Tapajós), in NC Brazil.
L. i. iris (Schinz, 1851) - E Pará (neighbourhood of Belém) E to NW Maranhão and S to upper R Xingu (Brazil).



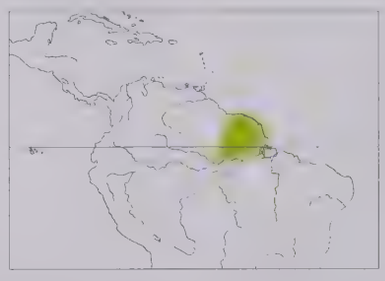
Descriptive notes. 9 cm; female 7·8-9·5 g. Has notably heavy bill. Male nominate race has narrow green band on forehead, and shiny opal-escent crown and nape; plumage otherwise mostly olive-green above and from chin to breast, yellow below; iris pale buff or cream; bill pale bluish; legs pinkish-flesh. Female has crown and nape green. Juvenile resembles female, but iris dark. Race *eucephala* male lacks green on forehead, female has bluish crown and nape. Voice. Male call a rather rapidly repeated "chi-wir".
Habitat. Humid forest and mature secondary woodland; below c. 200 m.
Food and Feeding. No data; probably similar to *L. coronata*.
Breeding. Female with fully formed egg in oviduct, Aug, in E Pará (Belém area). Male displays solitarily or at "exploded" lek, from low slender branches, with rapid flight manoeuvres. No other information.
Movements. No information; presumably resident.
Status and Conservation. Not globally threatened. Formerly considered Near-threatened. Uncommon to locally fairly common. Numbers undoubtedly reduced by deforestation within its limited range. Poorly known species.
Bibliography. Collar *et al.* (1994), Cracraft (1985), Forrester (1993), Haffer (1971, 1997b), Hellmayr (1929), Meyer de Schauensee (1982), Pinto (1953), Prum (1988), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Zimmer *et al.* (1997).

15. Orange-bellied Manakin

Lepidothrix suavissima

French: Manakin à ventre orange **German**: Orangebauchpipra **Spanish**: Saltarín Ventrinaranja
Other common names: Tepui Manakin

Taxonomy. *Pipra suavissima* Salvin and Godman, 1882, Merume Mountains and Bartica, Guyana.
Genus often merged with *Pipra*. Until recently treated as conspecific with *L. serena*, but differs markedly in voice and in syringeal anatomy, as well as in male plumage characters. Monotypic.
Distribution. Montane zone of S & SE Venezuela, NC Guyana, and adjacent extreme N Brazil.



Descriptive notes. 9 cm; 1 male 8·5 g. Male is black with contrasting white forecrown, bright azure-blue lower rump and uppertail-coverts, yellow-orange belly; iris dark brown; bill black; legs greyish to nearly black. Differs from *L. serena* in having belly more orange-coloured (less yellow), no orange-yellow spot on chest. Female is mostly green, with bluish forehead, duller and greyer face and throat, yellow belly and undertail-coverts. Juvenile resembles female; immature male has some black in plumage. Voice. Male call a sharp, nasal, upward-inflected "aank"; also a rapid, emphatic, piping series of 7-8 notes, rising and falling in pitch.
Habitat. Montane forest and forest borders; 500-1800 m, locally down to 250 m.
Food and Feeding. Small fruits and insects, snatched in hovering flight.
Breeding. Not recorded. Male displays solitarily, or occasionally at "exploded" lek, executes bursts of rapid flight manoeuvres from low slender branches.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Locally common to fairly common; easily overlooked. Montane forest in much of its range is extensive and mostly difficult of access.
Bibliography. Blake (1950), Chapman (1931), Friedmann (1948), Gilliard (1941), Hellmayr (1929), Hilty (2003), Mayr & Phelps (1967), Prum (1994b), Ridgely & Tudor (1994), Rodner *et al.* (2000), Snyder (1966), Stotz (1993), Stotz *et al.* (1996), Willard *et al.* (1991).

16. White-fronted Manakin

Lepidothrix serena

French: Manakin à front blanc **German**: Weißstirnpipra **Spanish**: Saltarín Frentiblanco

Taxonomy. [*Pipra*] *serena* Linnaeus, 1766, Crique Ipoucin, River Approuague, French Guiana.
Genus often merged with *Pipra*. Until recently treated as conspecific with *L. suavissima*, but differs markedly in voice and in syringeal anatomy, as well as in plumage characters of male. Monotypic.
Distribution. Extreme SE Guyana, Surinam, French Guiana and N Brazil N of Amazon (lower R Negro E to Amapá).

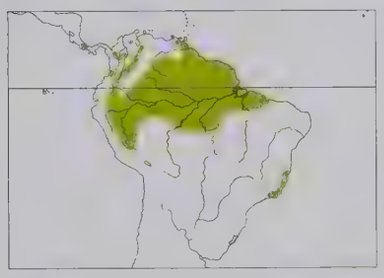
Descriptive notes. 9 cm; male average 10·7 g, female 11 g. Male is black with contrasting white forecrown, bright azure-blue lower rump and uppertail-coverts, orange-yellow patch on breast, yellow belly; iris dark brown; bill black; legs greyish to nearly black. Differs from *L. suavissima* in orange breast patch, purer yellow belly. Female is mostly green, crown tinged bluish, duller and greyer face and throat, yellower below, yellow belly and undertail-coverts. Juvenile resembles female; immature male has some black in plumage. Voice. Male call a soft, throaty, rolling "whree", given in long series; soft, descending "puurr" during display.
Habitat. Humid forest and forest edge; to 500 m.
Food and Feeding. Small fruits and insects. Fruits mainly small berries of Melastomataceae, with Rubiaceae next in importance. Items taken 1-6 m above ground, in aerial sally.
Breeding. Egg-laying from Oct/Nov (beginning of rainy season) probably to Apr in French Guiana; single record of laying in Feb in Surinam. Male display usually solitary, sometimes co-ordinated with those of others; long bouts of calling, with whirring flights between several perches. Nest a cup of whitish woody or herbaceous fibres, exterior covered with long moss filaments, some hanging below, producing total nest depth of up to 37 cm, placed 1-2 m above ground in horizontal fork of shrub or small tree. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. Resident. In radio-tracking study in French Guiana, adults largely sedentary when breeding, moving over much larger area (probably of several hundred hectares) during moult period; an immature male wandered over range of 24·1 ha.
Status and Conservation. Not globally threatened. Locally common. Very common throughout forested massif of interior French Guiana; during breeding season in latter country, home ranges of two adult males were 2·8 ha and 3·2 ha (centred on single display area and bathing site), and of two females 11·2 ha and 13 ha (including several male display areas and bathing sites).
Bibliography. Blake (1950), Cohn-Haft *et al.* (1997), Cracraft (1985), Dujardin (1987), Endler & Théry (1996), Forrester (1993), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1929), Meyer de Schauensee (1982), Novaes (1978a), Prum (1985, 1988, 1994b), Reynaud (1998), Ridgely & Tudor (1994), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Théry (1990a, 1990b, 1990c, 1992, 1997), Thiollay & Jullien (1998), Tostain (1988b), Tostain *et al.* (1992).

PLATE 12 ➤

PLATE 12

inches 4

cm 10



Genus *DIXIPHIA* Reichenbach, 1850

17. White-crowned Manakin

Dixiphia pipra

French: Manakin à tête blanche **German**: Weißscheitelpipra **Spanish**: Saltarín Coroniblanco
Other common names: Sclater's Manakin (NW & W races); Velvet/Zeledon's Manakin (*anthracina*)

Taxonomy. [*Parus*] *Pipra* Linnaeus, 1758, Surinam.
Genus often merged with *Pipra*. Races in Central America and W part of South American range differ vocally from E ones, and may represent a distinct species; taxonomic status of isolated race *cephaleucos* uncertain; further study required. Thirteen subspecies recognized.
Subspecies and Distribution.
D. p. anthracina (Ridgway, 1906) - C & E Costa Rica and W Panama (W of Canal Zone).
D. p. bolivari (Meyer de Schauensee, 1950) - NW Colombia (upper Sinú Valley E to S Bolívar).
D. p. minima (Chapman, 1917) - SW Colombia on W side of W Andes.
D. p. unica (Meyer de Schauensee, 1945) - subtropical zone of NC & S Colombia (Magdalena Valley).
D. p. coracina (P. L. Sclater, 1856) - NW Venezuela (Perijá Mts, and SE Lara S to SE Táchira) S, on E slope of E Andes, to E Ecuador and NC Peru (N of R Marañón).
D. p. discolor (J. T. Zimmer, 1936) - NE Peru.
D. p. occulta (J. T. Zimmer, 1936) - NC Peru on E side of C Andes.
D. p. pygmaea (J. T. Zimmer, 1936) - lower R Huallaga, in NC Peru.
D. p. comata (Berlepsch & Stolzmann, 1894) - EC Peru (S Pasco S to N Cuzco).
D. p. microlopha (J. T. Zimmer, 1929) - E Peru (S of R Marañón) and W Brazil.
D. p. pipra (Linnaeus, 1758) - S & E Venezuela, the Guianas, and lowland E Colombia and Brazil mainly N of Amazon (E to Amapá, crossing to S bank at Tefé).
D. p. separabilis (J. T. Zimmer, 1936) - S side of lower Amazon from R Tapajós E to N Maranhão.
D. p. cephaleucos (Thunberg, 1822) - coastal E Brazil (S Bahia S to Rio de Janeiro).

Descriptive notes. 9-10 cm; male average 11 g, female 12·8 g (*pipra*), male average 10·6 g, female 11 g (*separabilis*), sexes combined average 14 g (*anthracina*). Male nominate race is all black, apart from contrasting white crown and nape, nuchal feathers forming flattened crest; iris bright brick-red to brown-red; bill dark brownish-grey to blackish; legs purplish-pink to blackish. Female is green above, greyer on head, paler below, especially on throat and belly. Juvenile resembles female. Races differ primarily in extent of white on crown and nape of male, and extent of grey on head of female (least extensive and least obvious on E races): *anthracina* male has black bases of crown and nape (but not forehead) feathers, upperparts velvety black; *bolivari* resembles last but has black of plumage glossed blue; *unica* differs in having longer white crest, bases of head-top feathers entirely white; *minima* is like previous but much smaller, black more velvety; *coracina* male has black feather bases on head top, white extending farther back on nape, female is brighter than nominate, head entirely blue-grey, brighter olive above, pale olive with weak yellowish tinge below; *comata* has longer tail than previous, male head with most extensive white of all races, feather bases entirely white; *occulta* resembles previous, but nape feathers shorter, bases of crown and nape feathers sooty grey, shorter wing and tail, female rather pale, whitish below with yellowish on breast and flanks; *pygmaea* is like last but smaller, bases of crown feathers white, those of nape narrowly grey, female much paler; *microlopha* has shorter nuchal feathers than previous, marginally larger bill, female rather pale; *discolor* male has bluer (less violaceous) gloss than last, bases of crown as well as nape feathers grey; *separabilis* has narrow dusky feather bases on head top (sometimes white on forehead), moderate violaceous gloss above, rather dull and brownish below, immature male distinctive, with top of head entirely pale grey; *cephaleucos* male is identical to previous, immature male differs in white (not grey) head top, darker green back, darker underparts. Voice. Male call varies geographically: nominate race a thin, insect-like "chrrrrrr", lasting c. 1·5 seconds; *coracina* a loud "drrrrrr-eúw"; probably also other geographical variants.
Habitat. Humid forest and adjacent tall secondary woodland. Lowlands and mountains, to 1600 m in Andes; breeds mainly at 800-1500 m in Costa Rica.
Food and Feeding. Small fruits and insects. In French Guiana fruits mainly of Melastomataceae, with Rubiaceae next in importance. Items plucked or snatched from vegetation during rapid aerial sallies. Occasionally joins mixed-species flocks for brief periods.
Breeding. Egg-laying in Oct in Surinam, in Feb-May, Aug and Oct in French Guiana; in Brazil, Jun-Oct in Belém area and Nov in Manaus area. Male displays usually at "exploded" lek, from slender low branches, makes short stereotyped flights, often with crown feathers spread outwards. Nest a cup of fibres and fungal hyphae, covered on outside with dead leaves, built 1-3·5 m above ground in horizontal fork of shrub or small tree. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. Resident. In Costa Rica, occasionally descends to lower altitudes during wet season. In radio-tracking studies in French Guiana, adults (especially males) sedentary during breeding season, moving over much more extensive areas (probably of several hundred hectares) during moult period; two immature males ranged over, respectively, 18·7 ha and 20·9 ha.
Status and Conservation. Not globally threatened. Fairly common to common in much of E part of range; generally less common and more local in W. Isolated race *cephaleucos* in coastal E Brazil could potentially be threatened by habitat loss; protected population occurs in Sooretama Biological Reserve. In French Guiana, breeding-season home ranges of two adult males were 2·1 ha and 2·3 ha (centred on single display area and bathing site), and of two females 8·8 ha and 9·2 ha (including several male display areas and bathing sites).
Bibliography. Castro Astor *et al.* (1998), Cohn-Haft *et al.* (1997), Eisenmann (1955), Graves (1981, 1993), Haverschmidt (1968), Haverschmidt & Mees (1994), Heindl & Winkler (2003a), Hellmayr (1929), Hilty (1997, 2003), Hilty & Brown (1986), Iafrancesco *et al.* (1987), Oniki & Willis (1982), Oren & Parker (1997), Pinto (1953), Reynaud (1998), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Sick (1993, 1997), Schubart *et al.* (1965), Slud (1964), Snow, D.W. Genus *ANTILOPHIA* Reichenbach, 1850

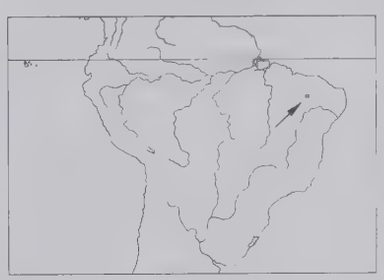
18. Helmeted Manakin

Antilophia galeata

French: Manakin casqué **German**: Helmpipra **Spanish**: Saltarín de Yelmo

Taxonomy. *Pipra galeata* M. H. K. Lichtenstein, 1823, São Paulo, Brazil.
Genus closely related to *Chiroxiphia*; occasional intergeneric hybrids between present species and *C. caudata* recorded. Monotypic.
Distribution. Tableland of C & S Brazil (S from C Maranhão, to W Paraná), just entering NE Bolivia and NE Paraguay.



Descriptive notes. 13·9-14·5 cm; male 18-26·5 g, female 18·8-26·2 g. Distinctively crested manakin with rather long and narrow tail. Male has red forehead to back, with showy erect frontal crest; rest of plumage black; iris dark brown; bill dark; legs pinkish. Female is olive above, with smaller frontal crest, slightly duller and paler below. Juvenile resembles female. Voice. Male call a series of fast, rich musical notes with rollicking cadence, with many variations; throaty "wreee pur", first note rising, given by both sexes.
Habitat. Mainly gallery woodland in *cerrado* region, locally also in buriti palm (*Mauritia vinifera*) groves and deciduous or swampy woodland, often with nearly impenetrable lower strata; mostly 500-1000 m. May fly over open areas between stands of gallery woodland.
Food and Feeding. Fruit and insects, taken in aerial sallies. Regularly accompanies mixed-species flocks.
Breeding. Egg-laying in Aug-Dec, mainly Sept-Nov. Nest a shallow cup made from fine twigs, rootlets and leaves, with hanging leaves on outside, suspended 0·5-10 m above ground in horizontal fork of tree or shrub. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common throughout range. Much suitable habitat remains within its extensive range, in most of which it is the only piprid species. Seems unlikely to be at any risk in foreseeable future. Present in numerous protected areas, e.g. Serra da Canastra, Brasília, Das Emas and Chapada dos Guimarães National Parks (Brazil).
Bibliography. 19. Araripe Manakin

Antilophia bokermanni

French: Manakin de Bokermann **German**: Araripe-Helmpipra **Spanish**: Saltarín de Araripe

Taxonomy. *Antilophia bokermanni* Coelho and Silva, 1998, Nascente do Farias, Chapada do Araripe, Ceará, Brazil.
Genus closely related to *Chiroxiphia*. Monotypic.
Distribution. S Ceará (Chapada do Araripe), in NE Brazil.

Descriptive notes. 15-15·5 cm; 19-20·5 g. Strikingly patterned piprid with erect frontal crest. Male has bright red crest, crown and nape to upper back; rest of plumage mainly white, except for contrasting black flight-feathers and tail, and black inner webs of some upperwing-coverts; iris russet; bill dark; legs dusky brown. Female is olive above, with smaller frontal crest, duller and paler below, especially on belly; differs from very similar female *A. galeata* in paler underparts. Juvenile apparently undescribed. Voice. Male call a repeated musical "guru-uí", both sexes a throaty "wreee pur" with ascending first note; very similar to calls of *A. galeata*.
Habitat. Evergreen secondary forest, moving occasionally into more open adjacent areas; c. 800 m.
Food and Feeding. Recorded as feeding on small fruits of *Cordia* (Boraginaceae).
Breeding. Two females had incubation patches at end Jul. No other information.
Movements. No information; hitherto recorded only from one restricted area.
Status and Conservation. CRITICAL. A very recently discovered species, first observed in 1996. Apparently confined to forested valley (or valleys) running down from the elevated Chapada do

On following pages: 20. Long-tailed Manakin (*Chiroxiphia linearis*); 21. Lance-tailed Manakin (*Chiroxiphia lanceolata*); 22. Blue-backed Manakin (*Chiroxiphia pareola*); 23. Yungas Manakin (*Chiroxiphia boliviana*); 24. Blue Manakin (*Chiroxiphia caudata*); 25. Pin-tailed Manakin (*Ilicura militaris*).

Araripe; known range covers no more than c. 1 km², and total population estimated at fewer than 250 individuals. Area where found lies within the Araripe National Forest, which is part of a large Environmental Protection Area; whole area is of high conservation priority and enjoys partial, but not yet legally binding, protection. Lowland forest adjacent to this species' habitat has already been cleared for commercial plantations, farming and human settlement; associated developments, e.g. road-building and construction of recreational facilities, represent a major threat. Conservation priorities include dedicated surveys of suitable habitat in nearby areas, aimed at determining the existence or otherwise of additional populations of this piprid. If its future is to be secured, effective protection of its habitat is a vital and urgent necessity.

Genus *CHIROXIPHIA* Cabanis, 1847

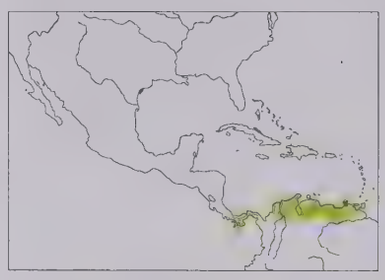
20. **Long-tailed Manakin**

Chiroxiphia linearis

French: Manakin fastueux **German**: Langschwanzpipra **Spanish**: Saltarín Colilargo

Taxonomy. *Pipra linearis* Bonaparte, 1838, Santa Efigenia, Oaxaca, Mexico.
Genus closely related to *Antilophia*. All members of present genus suggested by some as forming a superspecies. Has sometimes been treated as conspecific with *C. lanceolata* and *C. pareola*. Two subspecies recognized.
Subspecies and Distribution.
C. l. linearis (Bonaparte, 1838) - tropical zone of Pacific coastal S Mexico (extreme E Oaxaca, Chiapas) and Guatemala.
C. l. fastuosa (Lesson, 1842) - tropical zone of El Salvador S to NW Costa Rica.

Descriptive notes. 11·5 cm, excluding tail extensions 10-15 cm in male, 2-3 cm in female; male 16·8 g, female 19·1 g. Male has short black frontal crest, red crown patch, light blue back and scapulars; rest of plumage, including greatly elongated central rectrices, black; iris dark reddish-brown; bill black; legs rather dull yellow-orange. Differs from *C. lanceolata* in very much longer and less pointed central rectrices, duller leg colour. Female is olive-green, paler and yellower on throat and, especially, on belly and undertail-coverts. Juvenile resembles female; immature male acquires red crown and somewhat elongated central rectrices by age of 1 year, passes through sequence of distinct, age-specific intermediate stages, assumes full adult plumage in fourth year. Race *fastuosa* is brighter than nominate, red hindcrown feathers form short crest. Voice. Male call, given in duet with another male, a pure, musical "to-lay-do" or "te dee oh"; during courtship dance males alternately utter nasal, twanging "nyanyownh", and at end of dance dominant male gives sharp "buzz-weent".
Habitat. Dry forest and humid forest with abundant undergrowth, also gallery woodland, borders of mangrove swamps and tall second growth; to c. 1500 m.
Food and Feeding. Mainly fruits of trees and shrubs, also insects. Food items plucked or snatched in aerial sallies.
Breeding. Egg-laying in Mar-Aug in Costa Rica. Male displays low down on slender horizontal stems, where joined by one or two subordinate males, two birds alternately making fluttering upward leaps; on arrival of a female, jumps and hovers, then flutters backwards and down to perch, whereupon other male performs same movement, this continuing until sharp call by dominant male causes subordinate to leave; only dominant male mates with female. Nest a shallow cup containing leaves and sometimes grass blades, bark strips, moss or fern fragments, lined with fungal hyphae and leaf midribs, dead leaves hanging below for up to 8·5 cm, suspended 0·7-1·7 m above ground from fork of shrub or near end of small branch of small tree, attached by spider web or insect-cocoon threads, fungal rhizomorphs wrapped around twigs of fork; always sited so that adjacent shoots and leaves provide roof over nest. Clutch usually 2 eggs, records of single-egg clutches perhaps due to partial loss; no information on incubation and fledging periods. Breeding success in Costa Rica study area low: of 15 eggs observed, only one hatched and young did not fledge, presumed preyed on. Male does not reach dominant status until up to ten years.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Common to fairly common; locally abundant in Costa Rica, where present in Carara Biological Reserve. Relatively wide habitat tolerance should ensure its survival.



Bibliography. Beletsky (1998, 1999), Binford (1989), Ceballos & Valdelamar (2000), Dearborn (1907), Eisenmann (1955), Fogden (1993), Foster (1976, 1977a, 1977c, 1984, 1985, 1987), Griscom (1950), Hellmayr (1929), Henderson (2002), Howell & Webb (1995a), Komar & Domínguez (2001), Land (1970), McDonald (1987, 1989a, 1989b, 1993a, 1993b, 2003), McDonald & Potts (1994), Rowley (1984), Slud (1964), Stiles (1983, 1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Trainer & McDonald (1993, 1995), Trainer & Parsons (2001), Trainer *et al.* (2002), Wetmore (1941, 1944), Wheelwright (1985, 1988).

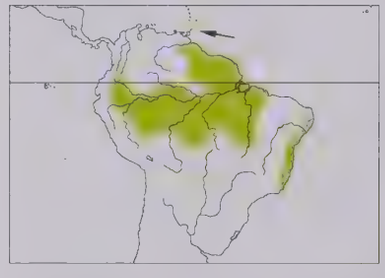
21. **Lance-tailed Manakin**

Chiroxiphia lanceolata

French: Manakin lancéolé **German**: Lanzettschwanzpipra **Spanish**: Saltarín Lanceolado

Taxonomy. *Pipra lanceolata* Wagler, 1830, "Guiana sive Cajenna"; error = Cerro Turumiquire, Sucre, Venezuela.
Genus closely related to *Antilophia*. All members of present genus suggested by some as forming a superspecies. Has sometimes been treated as conspecific with *C. linearis* and *C. pareola*. Monotypic.
Distribution. Pacific coastal region of extreme SW Costa Rica and Panama (including Coiba I and Cébaco I), N Colombia along Caribbean coast (including Santa Marta area), and N Venezuela N of R Orinoco (E, including Margarita I, to Paria Peninsula).

Descriptive notes. Male 13·5 cm (including elongated tail feathers), 2 birds 15·1 g and 17·9 g; female 13 cm (including elongated tail feathers), 14·1-19·8 g. Male has short black frontal crest, red crown patch, light blue back and scapulars; rest of plumage, including elongated central rectrices, black; iris dark reddish-brown; bill black; legs orange or orange-red. Differs from *C. linearis* in much shorter and sharply pointed central rectrices, brighter legs. Female is olive-green, paler and yellower on throat and, especially, on belly and undertail-coverts; like female *C. linearis*, but central rectrices pointed and somewhat shorter. Juvenile resembles female; immature male acquires red crown and somewhat elongated central rectrices by age of 1 year, then has several intermediate plumage stages. Voice. Male call, in duet with another male, a clear, musical "to-wit-doo"; during courtship dance repeated frog-like "na-a-a-a-a-a-a" and nasal "tuuuoo", similar to calls of *C. linearis*.
Habitat. Woodland with thick lower growth, from dry to humid, including patches of thick scrub and second-growth woodland in semi-open country; to 1500 m, locally to 1700 m.
Food and Feeding. Mainly fruits from shrubs and small trees, plucked in flight; also insects.
Breeding. Aug-Sept in Panama. Male displays low down on slender horizontal stems, where joined by a subordinate male, the two alternately making fluttering upward leaps and short flights; only dominant male mates with female. Nest a small shallow cup of grass and leaf fibres, slung c. 1 m above ground in horizontal forked twig of low bush, with dead leaves forming exterior covering and hanging loosely from sides and bottom. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Fairly common to locally common; common throughout N Venezuela. Relatively wide habitat tolerance should ensure its survival. Present in several protected areas, e.g. Tayrona National Park (Colombia), and Henri Pittier and Guatopo National Parks (Venezuela).



Bibliography. Blake (1958), Eisenmann (1955), Foster (1985), Friedmann & Smith (1950, 1955), Haffer (1975), Hallinan (1924), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Iafrancesco *et al.* (1987), Meyer de Schauensee (1982), Moermond & Denslow (1985), Pacheco & Laverde (2002, 2003), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Slud (1964), Snow, D.W. 22. **Blue-backed Manakin**

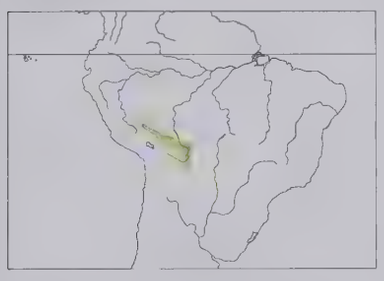
Chiroxiphia pareola

French: Manakin tijé **German**: Prachtpipra **Spanish**: Saltarín Dorsiazul
Other common names: Tobago Manakin (*atlantica*)

Taxonomy. [*Pipra*] *pareola* Linnaeus, 1766, Cayenne.
Genus closely related to *Antilophia*. All members of present genus suggested by some as forming a superspecies. Has sometimes been treated as conspecific with *C. linearis* and *C. lanceolata*. Formerly included *C. boliviana* as a race, but the two recently shown to differ in ecology and voice. Four subspecies recognized.
Subspecies and Distribution.
C. p. napensis W. deW. Miller, 1908 - S & SE Colombia (E of Andes), E Ecuador and N Peru (mainly N of R Marañón).
C. p. regina P. L. Sclater, 1856 - E Peru (S of R Marañón), W Brazil mostly S of Amazon (E to lower R Tapajós, also recorded N of Amazon at two sites W of R Negro) and extreme N Bolivia.
C. p. atlantica Dalmas, 1900 - Tobago.
C. p. pareola (Linnaeus, 1766) - E Venezuela (NE Bolívar), the Guianas, and NE & E Brazil (from Roraima, Obidos and right bank of R Tapajós E to Maranhão and S to Mato Grosso and SE Pará, also isolated coastal population from Rio Grande do Norte S to Espírito Santo).

Descriptive notes. 12-12·5 cm; male 17-21 g (nominate), 20-24·5 g (*atlantica*), female 18-21 g. Male nominate race has small black frontal crest, red crown patch, light blue back and scapulars; rest of plumage black; outer three primaries pointed, with shafts thickened and barbs reduced; iris dark reddish-brown; bill black; legs orange-red. Differs from almost identical *C. lanceolata* in lack of elongated central rectrices. Female is olive-green, paler and yellower on throat, with yellowish-white belly and undertail-coverts, flesh-coloured legs. Juvenile resembles female; immature male passes through sequence of intermediate plumages, in first stage acquiring red cap and sometimes some blue on back. Races differ in size and, mostly slightly, in male coloration: *atlantica* is largest; *napensis* is rather small, has red on crown brighter, blue on back somewhat darker; *regina* has crown patch golden-yellow, not red. Voice. Male advertising call a rolling "wrrrr", often followed by abrupt single or double "chup"; also a disyllabic "joy-ee"; male duets consist of series of almost perfectly synchronized "chup" notes; during courtship dance twanging notes given at increasing speed, ending with very loud "swee-eeék" by dominant male, similar to calls of *C. linearis*.
Habitat. Mainly humid forest and mature secondary woodland with abundant woody undergrowth; also drier forest and scrubby woodland in Tobago, Venezuela and Guyana. Mainly lowlands to c. 500 m; locally to 750 m in Ecuador and Peru. In E Brazil (S Bahia and Espírito Santo), where overlaps in range with *C. caudata*, is restricted to lowlands, whereas latter is confined to montane forest above 500 m.
Food and Feeding. Small fruits and insects. Items plucked or snatched from vegetation in sallying flights.
Breeding. Mar-Jul in Tobago; in Brazil, egg-laying in Sept-Apr in N (Belém area) and Nov in E (Bahia). Male displays low down on slender horizontal stems, where joined by one or two subordinate males, two birds perching close together and alternately making fluttering upward leaps; on arrival of a female, jumps and hovers, then flutters backwards and down to perch, whereupon other male performs same movement, this continuing until sharp call by dominant male causes subordinate to leave; dominant male gives butterfly-like flight around female, before mating. Nests in



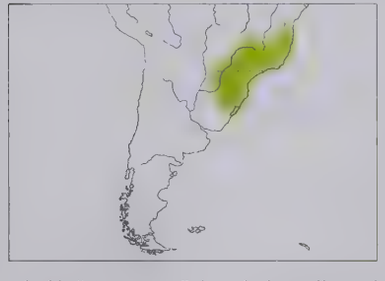
Tobago c. 2 m above ground, one a deep but flimsy cup of rootlets with base of dead leaves, saddled in lateral fork, another in leaf base of small palm; in Belém area 1-2 m above ground, usually with dry leaves and fibres hanging below. Clutch 2 eggs; in captivity, incubation period 17 days, young left nest after 15 days, fed by adult for several weeks.
Movement. Apparently sedentary.
Status and Conservation. Not globally threatened. Rather uncommon to locally common; common in parts of Tobago and the Guianas; fairly common but very local in Venezuela; apparently much less common in some W parts of range, e.g. Colombia, but uncommon to locally fairly common in Ecuador and Peru. Wide habitat tolerance should ensure its long-term survival.
Bibliography. Bangs & Penard (1918), Best *et al.* (1997), Butler (1979), Capparella (1988), ffrench (1991), ffrench & Kenefick (2003), Foster (1985), Gilliard (1959), Haffer (1997b), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1929), Herklots (1961), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Oren & Parker (1997), Ortiz & Carrión (1991), Parker & Remsen (1987), Pinto (1953), Pinto & Camargo (1961), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rutgers & Norris (1977), Sick (1960, 1993, 1997), Snow, D.W. (1963b, 1971b, 1976b, 1977b, 1985a), Snyder (1966), Spee (2001), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tostain *et al.* (1992), Zimmer & Hilty (1997).

23. Yungas Manakin

Chiroxiphia boliviana

French: Manakin des yungas **German**: Yungaspipra **Spanish**: Saltarín Yunga

Taxonomy. *Chiroxiphia pareola boliviana* J. A. Allen, 1889, Apolo, La Paz, Bolivia.
Genus closely related to *Antilophia*. All members of present genus suggested by some as forming a superspecies. Until recently considered a race of *C. pareola*, but now recognized as distinct on basis of ecology and voice. Monotypic.
Distribution. E slope of Andes from S Peru (S from Cuzco) S to SC Bolivia (S to Chuquisaca).



Descriptive notes. 13 cm; male 16·4 g, female 17·9 g. Male has small black frontal crest, dark red crown patch, light blue back and scapulars; rest of plumage black; outer three primaries pointed, with shafts thickened and barbs reduced; iris dark reddish-brown; bill black; legs purplish-brown. Distinguished from extremely similar *C. pareola* by distinctly longer tail, slightly darker red crown, darker legs. Female is olive-green, paler and greyer on belly. Juvenile apparently not described, presumably as female. Voice. Not well known; male advertising call a high-pitched "chereeo", with variations.
Habitat. Montane forest, at 650-2200 m.
Food and Feeding. No details; presumably much as for *C. pareola*. Often visits fruiting trees at forest edge.
Breeding. Not recorded.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Peruvian East Andean Foothills EBA and Bolivian and Peruvian Lower Yungas EBA. Locally fairly common. Frequently observed at Machu Picchu Historical Sanctuary.
Bibliography. Clements & Shany (2001), Fjeldså & Maijer (1996), Graves *et al.* (1983), Hellmayr (1929), Hennessey, Herzog & Sagot (2003), Parker & Remsen (1987), Parker & Wust (1994), Perry *et al.* (1997), Remsen & Traylor (1989), Ridgely & Tudor (1994), Schulenberg *et al.* (1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Montambault *et al.* (2002), Walker (2001).

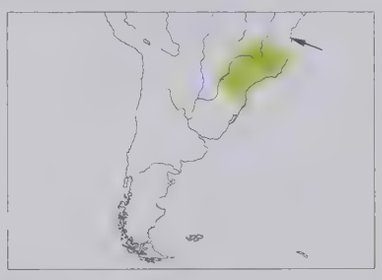
24. Blue Manakin

Chiroxiphia caudata

French: Manakin à longue queue **German**: Blaubrustpipra **Spanish**: Saltarín Azul
Other common names: Swallow-tailed Manakin

Taxonomy. *Pipra caudata* Shaw, 1793, Rio de Janeiro, Brazil.
Genus closely related to *Antilophia*, and occasional intergeneric hybrids between present species and *A. galeata* recorded; has apparently hybridized also with *Ilicura militaris*. All members of present genus suggested by some as forming a superspecies. Monotypic.
Distribution. SE Brazil (S Goiás and S Bahia S to W Paraná and Rio Grande do Sul), SE Paraguay and extreme NE Argentina (Misiones, NE Corrientes).

Descriptive notes. Male 15 cm, female 14·5 cm; mean 25·6 g. Male distinctively patterned, both sexes with elongated central rectrices. Male has black head with red band from forehead to nape; body and much of tail bright turquoise-blue, wings and outer tail black, undertail-coverts dusky; iris dark brown; bill flesh-coloured to sooty; legs pinkish to sooty. Female is dull green, paler below, a few having orange-yellow forehead more or less concealed by green mottling. Juvenile resembles female; immature male passes through a series of intermediate plumages, acquires full adult plumage when c. 3 years old. Voice. Male call a double "ptuwa ptuwa"; in male duet calls overlap, not well synchronized, giving impression of confused gabbling; during courtship dance loud guttural "kwa-a-a-a", at end of dance repetition of loud sharp "eek", similar to calls of *C. linearis*. Far-carrying "chorreeo cho-cho-cho" by both sexes in variety of contexts.
Habitat. Humid forest and secondary woodland, also edges. Mostly below 1500 m, occasionally to 1900 m. In E Brazil (S Bahia and Espírito Santo), where overlaps in range with *C. pareola*, confined to montane forest above 500 m, whereas that species is restricted to lowlands.
Food and Feeding. Small fruits and insects. Items plucked or snatched usually in aerial sally, but sometimes while perched.
Breeding. Egg-laying mainly in Aug-Feb. Male displays low down on slender horizontal stems, where joined by two (sometimes more) subordinate males, the three alternately making fluttering upward leaps; on arrival of a female, all three perch close together and take turns to jump and hover in front of her before landing at back of queue, shuffling forward in line as the individual nearest female jumps up, entire performance being terminated by sharp call by dominant male. Nest made of dry plant fibres, fungal rhizomorphs, sometimes including moss, with dry leaves attached to outside and hanging below, suspended from low fork of small tree or shrub. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Fairly common in most of range, and common in many areas. Might be subjected to habitat destruction in future, but ability to thrive in secondary woodland and edge habitats should ensure its survival. Present in several protected areas, e.g. Ybicuí National Park (Paraguay), Serra dos Órgãos and Itatiaia National Parks (Brazil), and Iguaçu and Iguazú National Parks (Brazil/Argentina).
Bibliography. Brooks *et al.* (1993), Canevari *et al.* (1991), Capper *et al.* (2000), Chebez *et al.* (1999), Clay (1995), Contreras (1983), Cracraft (1985), Ferro & Donatelli (2000), Forrester (1993), Foster (1977a, 1977b, 1981, 1984, 1985, 1987), Galetti & Pizo (1996), Guix (1995), Guix *et al.* (1992), Hayes (1995), Hellmayr (1929), Lowen *et al.* (1996), Mallet-Rodrigues & Marinho (2003), Marini & Hackett (2002), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), Pacheco & Parrini (1995), de la Peña (1989), Ridgely & Tudor (1994), do Rosário (1996), Saibene *et al.* (1996), Sick (1960, 1967, 1979b, 1993, 1997), Snow, D.W. (1976b, 1977b), Stotz *et al.* (1996), Tobias *et al.* (1993), Willis & Oniki (1988b).



Genus *ILICURA* Reichenbach, 1850

25. Pin-tailed Manakin

Ilicura militaris

French: Manakin militaire **German**: Rotbürzelpipra **Spanish**: Saltarín Militar

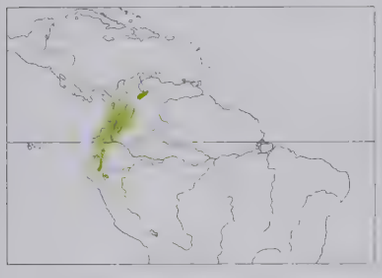
Taxonomy. *Pipra militaris* Shaw, 1809, South America = vicinity of Rio de Janeiro, Brazil.
Has apparently hybridized with *Chiroxiphia caudata*. Monotypic.
Distribution. SE Brazil in S Bahia, and from S Minais Gerais and Espírito Santo S to W Paraná and NE Santa Catarina.

Descriptive notes. Male 12·5 cm, female 11 cm; mean 14·6 g. Male has red patch on forehead, red lower back to uppertail-coverts; rest of upperparts, including tail and most of wings, black, inner remiges olive; central pair of tail feathers pointed, project 21-25 mm beyond rest; outer primaries unusually broad at end and narrow at base (instrumental in making whirring sound in flight during display), secondaries stiffened, with thickened shafts (used in making snapping sounds during display); rear part of head side pale greyish, underparts paler, whitest on belly, some blackish streaks on flanks; iris dull orange; bill pale horn, dark grey culmen; legs pinkish or flesh-coloured, with grey tinge. Female is olive above, grey on face and throat, light greyish-olive below, pointed central rectrices project 2-7 mm. Juvenile resembles female. Voice. Male advertising call an often repeated series of 5-8 high-pitched, rather soft, descending notes, "see-see-see-see-see"; similar series of 3-4 notes given by both sexes away from display area. Whirring and snapping sounds by displaying male in flight.
Habitat. Humid forest and mature secondary woodland, to 1200 m; in N of range only in mountains, but down to sea-level in S.
Food and Feeding. Small fruits and insects. Fruits recorded as eaten are those of Myrsinaceae (*Rapanea*), Loranthaceae and Melastomataceae. Food items plucked or snatched in aerial sally. Males attending display territories feed rapidly at nearby fruiting trees during short absences lasting 1·5-3 minutes. Regularly accompanies mixed-species foraging flocks.
Breeding. Few records. Laying probably in Nov-Feb. Male displays solitarily (but within hearing distance of one or two others), in small arena having many slender stems, raises rump feathers while singing, makes short rapid flights, makes short jumps over female crouched on perch. Nest a shallow "basket", 4 m above ground. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Considered uncommon to locally fairly common. Could possibly suffer from habitat destruction, but occurs in several protected forest areas, including Serra dos Órgãos, Tijuca and Itatiaia National Parks, as well as Augusto Ruschi Biological Reserve.
Bibliography. Anciães & del Lama (2002), Anciães & Straube (1997), Anciães *et al.* (2000), Cracraft (1985), Forrester (1993), Haffer (1985), Hellmayr (1929), Marini & Hackett (2002), Meyer de Schauensee (1982), Ridgely & Tudor (1994), do Rosário (1996), Santos & Ferreira (2000), Sick (1960, 1967, 1993, 1997), Silveira (1998), Snow & Snow (1985), Souza (1999), Stotz *et al.* (1996), Tobias *et al.* (1993), Venturini *et al.* (2001).

PLATE 13

inches 2,7

cm 7



Genus *MASIUS* Bonaparte, 1850

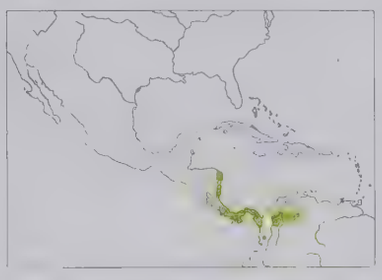
26. Golden-winged Manakin

Masius chrysopterus

French: Manakin aux ailes d'or **German**: Goldschwingenpipra **Spanish**: Saltarín Alidorado

Taxonomy. *Pipra chrysoptera* Lafresnaye, 1843, Santa Fe de Bogotá, Colombia.
Genus apparently closest to *Corapipo*, probably also close to *Ilicura*. Five subspecies recognized.
Subspecies and Distribution.
M. c. bellus Hartert & Hellmayr, 1903 - W Colombia on W side of W Andes E to W side of C range.
M. c. chrysopterus (Lafresnaye, 1843) - both sides of Andes in NW Venezuela and C Colombia (C range).
M. c. coronulatus P. L. Sclater, 1860 - W side of W Andes in SW Colombia and W Ecuador.
M. c. pax Meyer de Schauensee, 1952 - E side of Andes in S Colombia and Ecuador.
M. c. peruvianus Carriker, 1934 - extreme S Ecuador (S Zamora-Chinchipe) and N Peru (Cajamarca, N San Martín).

Descriptive notes. 11 cm; male 9-12·5 g, 2 females 12 g and 13·5 g. Male distinctive, feathers of forecrown projecting forwards, those of hindcrown and nape lying flat (scale-like), feathers on each side of crown projecting backwards to form two small lateral "horns". Male nominate race has golden-yellow forehead and crown, feathers of hindcrown and nape broadly tipped orange; rest of plumage mostly black, with pale yellow patch on throat and breast (largely concealed except at moment of giving advertising call), bright yellow underwing-coverts and inner webs of middle flight-feathers (conspicuous in flight), yellow inner webs of tail feathers (rarely visible); iris dark brown; bill pale flesh-coloured to steel-grey; legs pinkish to dull red or purplish. Female is olive, with yellow patch on throat, yellowish belly. Juvenile resembles female; immature male has some yellow on crown and throat, later acquires some black feathering in plumage (appears mottled). Races differ mainly in colour of male's hindcrown and nape: brown to reddish-brown in *bellus* and *coronulatus*, orange-red in *pax* and *peruvianus*. Voice. Male advertising call a low, nasal, frog-like "nurrt"; during display a high, continuous "seeeeeee" in flight to display-log, a double "tseet-tseet" just before landing, then "nurrt" during rebound.
Habitat. Wet montane forest and forest borders in subtropical zone and foothills; mainly 1000-2300 m, on Pacific slope down to 600 m in Colombia and to 400 m in Ecuador.
Food and Feeding. Small fruits and insects, taken in short flight sallies. Main food plants at two sites in Ecuador were four species of *Miconia* (Melastomataceae); other plant families exploited were Boraginaceae, Poaceae and Rubiaceae. Regularly accompanies mixed-species flocks, but also forages singly or in groups of 2-3 birds.
Breeding. Record of egg-laying in Jun in Colombia. Male display centred on log on forest floor, with stereotyped approach flight obliquely down to alight on log, followed by rebounding jump, also perches motionless on it with tail raised, also has bowing display with "horns" erected. Nest a thin-walled cup of rootlets and moss, suspended from horizontal fork 2-3 m over stream. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Inconspicuous and easily overlooked, so possibly more numerous than it appears to be. Known to occur in several protected areas, including Guaramacal National Park (Venezuela), Río Ñambí and La Planada Nature Reserves (Colombia) and Podocarpus National Park (Ecuador).
Bibliography. Allen (1998), Best *et al.* (1997), Bloch *et al.* (1991), Butler (1979), Chapman (1917c), Hellmayr (1929), Hilty (1997, 2003), Hilty & Brown (1986), Iafrancesco *et al.* (1987), Meyer de Schauensee (1945, 1982), Miller (1963), Ortiz & Carrión (1991), Parker (1992b, 1997), Parker *et al.* (1985), Pearson & Belebsky (2000), Prum & Johnson (1987), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg & Wust (1997), Snow & Snow (1992), Stotz *et al.* (1996), Williams & Tobias (1994).



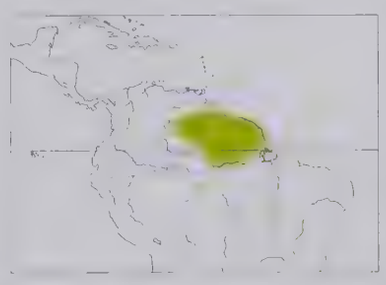
Genus *CORAPIPO* Bonaparte, 1854

27. White-ruffed Manakin

Corapipo leucorrhoa

French: Manakin orné **Spanish**: Saltarín Gorgiblanco Occidental
German: Westliche Weißkehlpipra
Other common names: White-bibbed Manakin (*leucorrhoa*)

Taxonomy. *Pipra leucorrhoa* P. L. Sclater, 1863, Bucaramanga, Santander, Colombia.
Genus probably close to *Masius*; has also been suggested as possibly sister to *Heterocercus* on basis of display behaviour and nest architecture. Probably forms a superspecies with *C. gutturalis*. W races *altera* and *heteroleuca* sometimes treated as a separate species, on basis mainly of greatly reduced outer primary. Three subspecies recognized.
Subspecies and Distribution.
C. l. altera Hellmayr, 1906 - Caribbean slope of Central America S from E Honduras, Pacific slope of S Costa Rica and Panama (except W Chiriquí), and NW Colombia (W of Atrato Valley).
C. l. heteroleuca Hellmayr, 1910 - Pacific slope of SW Costa Rica and W Panama (W Chiriquí).
C. l. leucorrhoa (P. L. Sclater, 1863) - locally in Perijá Mts, W Venezuela (lower slopes of Andes) and NC & W Colombia (S to middle Magdalena Valley, E to NW Arauca, also Pacific slope in Valle).



Descriptive notes. 9·5-10 cm; male 11·1 g, female 12·5 g. Male has white throat feathers elongated at sides to form ruff; rest of plumage glossy blue-black, some white on under-tail-coverts; iris dark brown; upper mandible blackish, cutting edges and lower mandible bluish-grey; legs rather dull reddish-pink, feet sometimes darker and greyer. Female is olive, with pale greyish throat, pale yellowish belly, lead-grey legs. Juvenile resembles female; immature male has paler grey throat, often with varying amount of white, acquires blackish face mask and white throat in second year. Race *altera* has outermost primary very short and narrow, much smaller than that of nominate; *heteroleuca* has outer primary reduced like previous, but white on throat less extensive. Voice. Male advertising call a high, rolling "prreeet"; also a sharp "seee"; in display, male landing on log makes a dull wing-snap, followed immediately by vocal "chee waa".
Habitat. Humid forest and tall secondary growth, also edges with fruiting trees, in foothills and lower mountain slopes. Sea-level to 1500 m in Central America; to 1200 m in Venezuela, and at 200-1500 m (above 400 m when breeding) in Colombia.
Food and Feeding. Mainly small fruits, with small proportion of insects and spiders. In small study area in Costa Rica, total of 57 species of fruit, mainly of Melastomataceae and Rubiaceae, recorded in diet. Females more insectivorous than males, especially during breeding season. Food items plucked or snatched in upward aerial sally. Sometimes joins mixed-species foraging flocks.
Breeding. Egg-laying in Mar-Jun in Costa Rica. Male display centred on log on forest floor, alone or with other males (adult and immature) and at times co-ordinated, includes steep upward flight from log followed by fast landing with rebounding jump with "about-face" turn, also slow flights with fluffed plumage to and from log; dominant male alone present when female visits, his pre-mating display elaborate, a series of flight displays close to ground, ending with female perching on central part of log, from which male flies up in steep spirals to above forest canopy, hovers briefly, then plummets down to alight beside her on log. Nest a small cup made of thin brown filaments or blackish fungal rhizomorphs, with leaf skeletons attached to bottom, slung in horizontal fork 5-7 m above ground. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. Largely resident. In S Costa Rica, race *altera* descends to foothills and adjacent lowlands between about Jul and Dec/Jan, and sporadically at other seasons, females probably moving farther downhill on average than males. Possibly similar altitudinal movements in Panama.
Status and Conservation. Not globally threatened. Common in Costa Rica, fairly common to common in Panama; uncommon and very local in Venezuela and Colombia. Populations of NW South America fragmented and severely reduced by forest destruction.
Bibliography. Beletsky (1998), Chapman (1917c), Cooper (1997), Davis (1982), Eisenmann (1955), Fogden (1993), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Iafrancesco *et al.* (1987), Levey & Stiles (1994), Loiselle & Blake (1999), Luck & Daily (2003), Meyer de Schauensee (1982), Moermond & Denslow (1985), Monroe (1968), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Rosselli (1989, 1994), Rosselli *et al.* (2002), Sekercioglu *et al.* (2002), Skutch (1967, 1969), Slud (1960, 1964), Stiles (1983, 1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972).

28. White-throated Manakin

Corapipo gutturalis

French: Manakin à gorge blanche **Spanish**: Saltarín Gorgiblanco Oriental
German: Östliche Weißkehlpipra

Taxonomy. [*Pipra*] *gutturalis* Linnaeus, 1766, Cayenne.
Genus probably close to *Masius*; has also been suggested as possibly sister to *Heterocercus* on basis of display behaviour and nest architecture. Probably forms a superspecies with *C. leucorrhoa*. Monotypic.
Distribution. S Venezuela (Bolívar, N Amazonas), the Guianas and N Brazil (Roraima E to Amapá, S locally to Manaus area).

Descriptive notes. 8·5-9·5 cm; male 8·1 g, female 8·8 g. Male has white on throat extending down to upper breast, where ends in a point; rest of plumage glossy blue-black, inner webs of inner primaries white (white patch in flight); iris dark; bill pale greyish-horn or pale flesh-coloured, darker and greyer above; legs purplish. Female is dull olive above, mostly greyish-white below, looking paler-bellied than females of most similar species, legs often lead-grey or greyish. Juvenile resembles female; immature male has white throat, later acquiring some black feathering on body. Voice. Both sexes give high, thin "seeu-see" and "chip" notes. Male advertising call a lengthened version, "seeu-see-ee-ee-ee"; in display-flight to log 2-10 high "seee" notes, a "pop" wing noise just before landing, then a complex "tickee-yeah" during rebound.
Habitat. Humid forest, occasionally at borders, mainly in hilly areas; 200-1100 m in Venezuela, 400-700 m in Surinam.
Food and Feeding. Small fruits and insects; fruits of Melastomataceae, followed by Rubiaceae, main components of diet in French Guiana. Items taken mainly in aerial sallies. Tends to forage at higher levels than most other piprids. Regularly accompanies mixed-species feeding flocks.
Breeding. Record of egg-laying in Oct in French Guiana. Male display centred on large log on forest floor, sometimes with other males, sometimes well separated from them in "exploded" lek, includes slow flight to log, from which "bounces" up and alights short distance away, facing in

On following pages: 29. White-collared Manakin (*Manacus candei*); 30. Orange-collared Manakin (*Manacus aurantiacus*); 31. Golden-collared Manakin (*Manacus vitellinus*); 32. White-bearded Manakin (*Manacus manacus*).

opposite direction; pre-mating display, by dominant male alone, a spiralling upward flight to above canopy, plummeting back to log. Nest a very small cup, of moss on outside, lined with thin layer of black fungal rhizomorphs (*Marasmius*), 8·3 m above ground in horizontal fork of small tree, bound to supporting twigs by cobweb. Clutch size apparently not documented, presumably 2 eggs; no information on incubation and fledging periods.
Movements. Resident. In French Guiana, colour-ringed adult males ranged over 2-2·5 ha during breeding season, females over 9-10 ha.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common in Venezuela; locally common in the Guianas. Difficult to observe and easily overlooked.

Genus *MANACUS* Brisson, 1760

29. White-collared Manakin

Manacus candei

French: Manakin à col blanc **German**: Weißbandpipra **Spanish**: Saltarín Cuelliblanco
Other common names: Almirante Manakin ("*M. cerritus*")

Taxonomy. *Pipra candei* Parzudaki, 1841, Trujillo, Honduras.
Genus possibly closest to *Chiroxiphia* and *Antilophia*. Its four members form a superspecies, and all sometimes treated as conspecific under the name *M. manacus*. Present species hybridizes with *M. vitellinus* in NW Panama (Bocas del Toro); hybrid forms have been treated as a distinct species, *M. cerritus*. Monotypic.
Distribution. Caribbean slope from SE Mexico (N Oaxaca) S to extreme W Panama (NW Bocas del Toro).

Descriptive notes. 11-12 cm; male 18·8, female (some possibly during egg-laying) 20·9 g. Male has black cap, rest of head and forebody (to upper back and upper breast) white, throat feathers elongated (projected forwards well beyond bill tip in display); black central back, wings and tail, olive lower back to uppertail-coverts; outer primaries thin and curved, secondaries with thickened shafts; yellow from lower breast downwards; iris dark brown; bill blackish; legs orange. Female is olive-green, yellower on belly. Juvenile resembles female; immature male has pale grey throat and upper chest, may acquire full adult plumage at c. 1 year. Voice. Male calls at lek a rolling "preew" or double "prrr-weeu", first note rolling, second note clear; also loud wing-snaps during display.
Habitat. Edges of humid evergreen forest, secondary woodland and thickets, locally cocoa and other plantations; sea-level to 700 m.
Food and Feeding. Small fruits and insects, plucked or snatched from vegetation in aerial sally.
Breeding. Apr-Aug in Costa Rica. Male displays with others at lek, each clearing a small "court" in which several vertical stems present, displays involve mainly jumps between stems with "about-face" on landing, also occasional crouching with head retracted, body swaying and wings beating, and with throat feathers projected forwards; when female visits, both sexes perform co-ordinated to-and-fro jumps between mating stem and an adjacent one, the two crossing in mid-air, female finally landing on mating perch, male then giving pre-mating display involving jump to ground, leap up to mating stem and slide down stem. Nest a shallow cup of black fungal rhizomorphs and fine brown fibres, often lined with filamentous *Myriocarpa* inflorescences, these sometimes dangling below for up to 1·2 m, outside usually decorated with green moss, suspended in horizontal fork. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Fairly common to common throughout range. Has quite wide habitat tolerance; does not require undisturbed primary forest.
Bibliography. Angehr (2003), Bangs (1903), Beletsky (1998, 1999), Binford (1989), Bostwick & Prum (2003), Brodkorb (1943), Brumfield *et al.* (2001), Butlin & Neems (1994), Cooper (1997), Dearborn (1907), Eisenmann (1955), Fogden (1993), González-García (1993), Haffer (1967), Hellmayr (1929), Henderson (2002), Herrera-Rosales (1998), Horwich (1990), Howell, S.N.G. & Webb (1995a), Howell, T.R. 30. Orange-collared Manakin

Manacus aurantiacus

French: Manakin à col orange **German**: Orangebandpipra **Spanish**: Saltarín Cuellinaranja

Taxonomy. *Chiromachaeris aurantiaca* Salvin, 1870, Mina de Chorcha and Bugaba, Chiriquí, Panama.
Genus possibly closest to *Chiroxiphia* and *Antilophia*. Its four members form a superspecies, and all sometimes treated as conspecific under the name *M. manacus*. Alternatively, present species has been considered by some to be conspecific only with *M. vitellinus*. Monotypic.
Distribution. Pacific lowlands and foothills of S Costa Rica and SW Panama.
Descriptive notes. 9·5-10 cm; 15·5 g. Male has black cap, rest of head and forebody (to upper back and upper breast) orange to golden-orange, throat feathers elongated (projected forwards slightly beyond bill tip in display); black central back, black wings and tail with some olive admixed, olive lower back to uppertail-coverts; outer primaries very thin and stiff, secondaries with thickened shafts and stiff outer webs; yellow with some admixed olive from lower breast downwards; iris

dark brown; bill blackish; legs reddish-orange. Female is olive above, more yellowish below, breast and flanks olive-green. Juvenile resembles female, but legs paler; immature male has golden tinge on breast. Voice. Male call at lek a clear "cheeu"; loud wing-snaps during display.
Habitat. Humid forest, neighbouring second-growth woodland and taller thickets, locally also shady plantations; lowlands to 1100 m.
Food and Feeding. Small fruits and insects, seized in aerial sally. Regularly forages above army ants.
Breeding. Egg-laying in Mar-Sept, mainly Mar-Jun, in S Costa Rica. Male displays at lek with others, each clearing a small "court" in which several vertical stems present, displays mainly by jumping between stems with "about-face" on landing, also occasional crouching with head retracted, body swaying and wings beating, and with throat feathers projected forwards; when female visits, both sexes perform co-ordinated jumps back and forth between mating stem and an adjacent one, crossing in mid-air, female finally landing on mating perch, male then giving pre-mating display involving jump to ground, leap up to mating stem and slide down stem. Nest a shallow cup, usually light in colour, made of fine filaments, strips of bark, rootlets and bast fibres, rarely with any pieces hanging below; suspended in horizontal fork, and bound to it with cobwebs, mostly 0·6-2·5 m above ground, rarely to 5·5 m. Clutch 2 eggs; incubation 18 to nearly 20 days; fledging usually 13-15 days.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. Locally common to fairly common. Has declined considerably in much of Panama as a result of deforestation; possibly still fairly numerous in parts of W Chiriquí. Able to survive in secondary and degraded habitats, but disappears from areas where most of vegetation cleared.
Bibliography. Angehr (2003), Bostwick & Prum (2003), Delgado (1985), Eisenmann (1955), Engleman (1996b), Hellmayr (1929), Ridgely & Gwynne (1989), Ridgway (1907), Sekercioglu *et al.* (2002), Skutch (1969), Slud (1964), Stiles (1983, 1985), Stiles & Skutch (1989), Wetmore (1972).

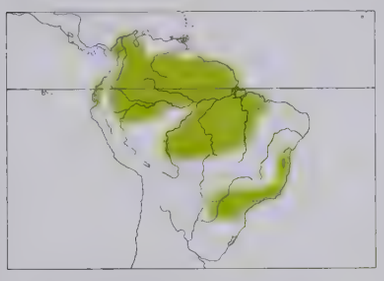
31. Golden-collared Manakin

Manacus vitellinus

French: Manakin à col d'or **German**: Goldbandpipra **Spanish**: Saltarín Cuellidorado
Other common names: Greenish-bellied Manakin (*viridiventris* and *milleri*); Almirante Manakin ("*M. cerritus*")

Taxonomy. *Pipra vitellina* Gould, 1843, Panama City, Panama.
Genus possibly closest to *Chiroxiphia* and *Antilophia*. Its four members form a superspecies, and all sometimes treated as conspecific under the name *M. manacus*. Alternatively, present species has been considered by some to be conspecific only with *M. aurantiacus*. Hybridizes with *M. candei* in Panama (Bocas del Toro), where hybrid forms have been treated as a distinct species, *M. cerritus*; hybridizes also with *M. manacus* in Colombia (lower Cauca Valley, also SW Cauca). Four subspecies recognized.
Subspecies and Distribution.
M. v. vitellinus (Gould, 1843) - Panama (E from Bocas del Toro) and NW Colombia (N Chocó, and N Antioquia around Golfo de Urabá).
M. v. amitinus Wetmore, 1959 - Escudo de Veraguas I, off N Panama (Bocas del Toro).
M. v. milleri Chapman, 1915 - N Colombia in valleys of Sinú and lower Cauca.
M. v. viridiventris Griscom, 1929 - W Colombia W of W Andes (S to SW Cauca), also on E side in upper Cauca Valley.

Descriptive notes. 10-11 cm; male 19·3 g, female 17·1 g. Male nominate race has black cap, golden-yellow on rest of head, upper mantle, shoulders, and chin to breast, throat feathers elongated (projected forwards well beyond bill tip in display); black back, wings and tail, olive lower back; four outermost primaries very narrow and stiff, secondaries with unusually thick shafts and stiff outer webs; lower underparts pale olive; iris dark brown; bill blackish; legs reddish-orange. Female has dull olive head and upperparts, paler and more olive-yellow below. Juvenile resembles female. Races differ mainly in size and in intensity of male coloration: *amitinus* is noticeably larger than others; *milleri* resembles nominate; *viridiventris* has brighter lemon-yellow throat. Voice. Male calls at lek a slightly trilled "peerr" and a clear "cheepooh"; also loud wing-snaps during display.
Habitat. Forest borders and secondary woodland, also dense regenerating clearings; lowlands and foothills, to 450 m in Panama, to 1200 m in Colombia.
Food and Feeding. Small fruits and insects, plucked or snatched in short aerial sallies.
Breeding. Egg-laying in Feb-Aug in Panama; in Colombia Feb-May in N (Chocó, N Antioquia), probably Jul in S (Valle). Male displays with others at lek, each clearing a small "court" in which several vertical stems present, displays mainly by jumping between stems with "about-face" on landing, also occasional crouching with head retracted, body swaying and wings beating, and with throat feathers projected forwards; when female visits, both sexes perform co-ordinated to-and-fro jumps between mating stem and an adjacent one, crossing in mid-air, female finally landing on mating perch, male then jumping to ground, leaping back up to mating stem and sliding down it. Nest a thinly woven shallow cup of rootlets and fungal hyphae, lined with finer material, slung between horizontal supports, and secured with cobweb, 0·6-1·5 m above ground. Clutch 2 eggs; incubation period not documented; fledging period 13-15 days.
Movements. Apparently sedentary.
Status and Conservation. Not globally threatened. The most abundant manakin over much of its range. Common in most of Panama, including both sides of Canal area; very common to common throughout Colombian range.
Bibliography. Angehr (2003), Bartholomew *et al.* (1983), Brumfield *et al.* (2001), Bucher & Worthington (1982), Butlin & Neems (1994), Chapman (1915, 1935), Cracraft (1985), Eisenmann (1955), Haffer (1967, 1975), Hellmayr (1929), Hilty (1997), Hilty & Brown (1986), McDonald *et al.* (2001), Meyer de Schauensee (1982), Moermond & Denslow (1985), Parsons *et al.* (1993, 1994), Piertney *et al.* (2002), Ridgely & Gwynne (1989), Ridgely & Tudor



(1994), Ridgway (1907), Robbins *et al.* (1985), Saldanha *et al.* (2000), Schlinger *et al.* (2001), Schultz *et al.* (2001), Sick (1960), Snow (1962a), Stotz *et al.* (1996), Wetmore (1972), Willis & Eisenmann (1979), Worthington (1982a, 1982b, 1983, 1989).

32. White-bearded Manakin

Manacus manacus

French: Manakin casse-noisette **German**: Weißbrustpipra **Spanish**: Saltarín Barbiblanco
Other common names: Bearded Manakin (when all congeners considered conspecific)

Taxonomy. [*Pipra*] *manacus* Linnaeus, 1766, Surinam.
Genus possibly closest to *Chiroxiphia* and *Antilophia*. Its four members form a superspecies, and all sometimes treated as conspecific. Present species hybridizes with *M. vitellinus* in Colombia (lower Cauca Valley, also SW Cauca). Almost all geographical variation probably clinal, and some described races perhaps not tenable; full revision of taxonomy desirable. Fifteen subspecies recognized.
Subspecies and Distribution.
M. m. abditivus Bangs, 1899 - N Colombia (Santa Marta region, lower Cauca Valley, lower and middle Magdalena Valley).
M. m. flaveolus Cassin, 1851 - upper Magdalena Valley (C Colombia).
M. m. bangsi Chapman, 1914 - SW Colombia (S from SW Cauca) and extreme NW Ecuador (N Esmeraldas, Imbabura).
M. m. leucochlamys Chapman, 1914 - NW & W Ecuador (W Esmeraldas and Pichincha S to N Guayas).
M. m. maximus Chapman, 1924 - SW Ecuador (E Guayas and extreme W Chimborazo S to W Loja) and extreme NW Peru (Tumbes).
M. m. interior Chapman, 1914 - NW & SC Venezuela, Colombia E of Andes, E Ecuador, NE Peru, and NW Brazil (on upper R Negro).
M. m. trinitatis (Hartert, 1912) - Trinidad.
M. m. umbrosus Friedmann, 1944 - limited area of S Venezuela in C Amazonas.
M. m. manacus (Linnaeus, 1766) - the Guianas, S Venezuela (R Casiquiare region, in S Amazonas), and NE Brazil N of lower Amazon.
M. m. expectatus Gyldenstolpe, 1941 - W Brazil (R Juruá), possibly also adjacent NE Peru (E Loreto).
M. m. subpurus Cherrie & Reichenberger, 1923 - SC Brazil.
M. m. purus Bangs, 1899 - S bank of lower Amazon in Brazil (R Madeira probably to left bank of R Xingu).
M. m. longibarbatus J. T. Zimmer, 1936 - S bank of lower Amazon in Brazil (right bank of R Xingu E to right bank of R Tocantins).
M. m. purissimus Todd, 1928 - E Brazil from right bank of R Tocantins E to N Maranhão.
M. m. gutturosus (Desmarest, 1806) - E & SE Brazil (Alagoas, Bahia and Minas Gerais S to extreme SE Mato Grosso, Santa Catarina and extreme N Rio Grande do Sul), SE Paraguay and extreme NE Argentina (Misiones).

Descriptive notes. 10-11 cm; male 18·3 g, female 16·5 g (*trinitatis*), male 17·5 g, female 16 g (*manacus*, French Guiana), male 16·4 g, female 15·4 g (*manacus*, Surinam), male 15·7 g, female 14·8 g (*subpurus*). Male nominate race has black cap, back, wings and tail; rest of plumage mostly white, rump and uppertail-coverts grey, flanks and belly tinged grey; throat feathers elongated (projected forwards well beyond bill tip in display); four outermost primaries very narrow and stiff (instrumental in producing grasshopper-like whirring in flight), secondaries with unusually thick shafts and stiff outer webs (producing loud snaps during display); iris dark brown; bill blackish, cutting edges and lower mandible often paler (grey); legs reddish-orange. Female is olive above, greyer and paler below, especially on throat and belly; differs from females of congeners in having less yellowish underparts. Juvenile resembles female; immature male acquires some adult-like feathers after a few months, gains full adult plumage when just over 1 year old. Races vary mainly in size, in width of white collar of male and in extent of grey in underparts: *abditivus* has throat feathers very long and stiff; *flaveolus* has throat and collar tinged creamy yellow; *bangsi* is small, grey-bellied, with narrow white collar; *leucochlamys* differs from last in broader white mantle, white belly; *maximus* is like previous but larger throughout, white feathers of throat and mantle longer; *interior* has rump and lower underparts paler grey than nominate; *umbrosus* differs from last in having grey areas much darker; *trinitatis* is large, has broadest white collar, female yellower below; *expectatus* is much smaller than last; *subpurus* has rump rather dark grey, faint greyish wash on breast and abdomen, more extensive darker grey on sides and flanks, white undertail-coverts; *purus* differs from previous in having less black on back, paler grey rump, no grey wash on breast, paler and less extensive grey on flanks; *longibarbatus* is similar to nominate but throat feathers longer, white on mantle broader and purer white, grey of rump on average broader, median (sometimes also greater) upperwing-coverts white subterminally, lower belly and thighs paler grey; *purissimus* is like previous but throat feathers shorter, lower belly and thighs more whitish, wing longer, outer primary broader; *gutturosus* has darkest and most extensive grey below, extending from breast to vent. Voice. Male calls at lek a rather plaintive, slightly trilled "peerr", changing in excitement to a louder, high-pitched "chwee", and distinct disyllabic "chee-poo" at start of display bout; also loud wing-snaps.
Habitat. Forest edges, especially where woody undergrowth is thick, also low shrubby forest and secondary woodland. Mainly below 1000 m, often lower, below 800 m; old records from 1300 m in SW Ecuador (W Loja). Marked preference for nesting beside, or even over, woodland streams.
Food and Feeding. Mainly small fruits, also insects. In Trinidad study area, fruits of 105 plant species, from 27 families, recorded as eaten; Melastomataceae the most important family, followed by Rubiaceae. Insects include beetles (Coleoptera), flies (Diptera) and alate termites (Isoptera); proportionately more insects fed to young than eaten by adults themselves. Fruits plucked in flight, but sometimes, if accessible, from perched position; insects snatched from vegetation in flight, mostly at low levels. Not uncommonly follows army ants, taking insects disturbed by them.
Breeding. In Trinidad, egg-laying in Jan-Sept (exceptionally, Dec), peak May-Jun, month of starting varying annually, and up to five breeding attempts in single season; breeding recorded in Jan, Mar and Aug in Surinam; in Brazil, Aug-Apr in N (Belém area) and Dec in SE. Male displays at lek, in compact group with up to 50 or more others, each clearing a small, roughly circular "court" in which usually 2-4 vertical stems present, display repertoire of three distinct elements, all with long throat feathers projected forwards, commonest one being jumps between stems with "about-face" on landing, less often jump to ground and back up to stem, and crouching with head retracted, body swaying and wings beating and fanned; when female visits, both sexes perform co-ordinated to-and-fro jumps between mating stem and an adjacent one, the two crossing in mid-air, female finally landing on mating perch, male then giving stereotyped sequence of jump to ground, leap back up to mating stem and slide down stem on to female's back. Nest a thinly woven shallow cup made of rootlets, black fungal hyphae and occasionally dead leaves, inner lining of fine plant material (mainly very fine-branching fruit panicles of the melastome *Nepsera aquatica* in Trinidad and Belém area); slung between horizontal supports and secured with cobweb, mainly 0·5-1·5 m above ground, usually beside or overhanging woodland stream. Clutch 2 eggs; incubation period 18-19 days; fledging period 13-15 days. Nesting success low: in Trinidad study, of 227 nests in which eggs laid, 19% produced fledged young, with average of 0·33 fledglings per nest for all nesting attempts.
Movements. Resident. In radio-tracking study in French Guiana, adults largely sedentary when breeding, moving over larger area (probably of several hundred hectares) during moult period; immature males wandered over ranges of 20·1 ha and 20·3 ha.
Status and Conservation. Not globally threatened. Common in many parts of its wide range, but more local in areas of extensive unbroken forest. Common in Trinidad; common in N & C parts of Colombia, less numerous towards S; fairly common in Ecuador; common in NE Peru but rare in NW. In French Guiana during breeding season, home ranges of two adult males were 2·1 ha and 2·5 ha (centred on single display area and bathing site), and of two females 13 ha and 14·1 ha (including several male display areas and bathing sites).
Bibliography. PLATE 14

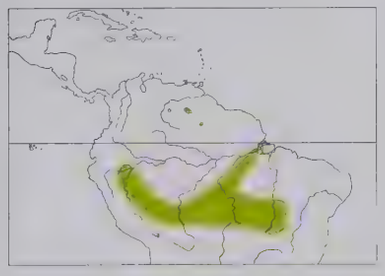
inches 2
cm 5

Genus *MACHAEROPTERUS* Bonaparte, 1854

33. Fiery-capped Manakin

Machaeropterus pyrocephalus



French: Manakin tête-de-feu **German**: Feuerkopfpipra **Spanish**: Saltarín Encendido

Taxonomy. *Pipra pyrocephala* P. L. Sclater, 1852, locality unknown = Ucayali, upper Amazon, Peru.
Two subspecies recognized.

Subspecies and Distribution.

M. p. pallidiceps J. T. Zimmer, 1936 - S Venezuela (lower Caura Valley and middle Caragua Valley, in Bolívar, also single record from NW Amazonas) and extreme N Brazil (N Roraima).

M. p. pyrocephalus (P. L. Sclater, 1852) - widely scattered localities in E Peru, N Bolivia and Amazonian Brazil (mainly in S, E to S Amapá and Goiás).

Descriptive notes. 8-9 cm; 9-8 g. Male has golden cap and nape with red median stripe, rest of upperparts rosy rufous to maroon; auriculars, tail and most of wing olive, some whitish on inner secondaries, series of black spots on tertials (conspicuous in display); inner secondaries somewhat twisted; tail feathers short and pointed, with thickened rachi; throat whitish, rest of underparts streaked dull pink and whitish; iris dark red; bill blackish, paler base of lower mandible; legs pinkish to purplish-flesh. Female is olive above, pale greyish on throat, pale and dull olive with blurry streaking below, belly tinged yellowish. Juvenile resembles female; immature male usually has some golden-yellow on forecrown. Race *pallidiceps* male has yellow of head paler and median stripe much less prominent than in nominate. Voice. Male advertising call a high-pitched bell-like or frog-like "pling", usually at long intervals; in display, a mechanical loud wing noise, "zssssss", produced by modified secondaries; in flight, rattling mechanical sound like that of large beetle (Coleoptera).

Habitat. Humid forest and mature secondary woodland, also forest borders; transitional forest apparently favoured in some area, e.g. SE Peru (Madre de Dios). To c. 1200 m, mostly lower; 100-200 m in Venezuela.

Food and Feeding. Small fruits (especially of Melastomataceae) and insects, plucked or snatched in flight.

Breeding. Nest found in Mar in Venezuela. Male displays at "exploded" lek, within hearing distance of others, often accompanied by one other male, hangs downwards from slender horizontal perch and twists so rapidly from side to side that it becomes a blur. Single known nest, of race *pallidiceps*, a small cup lined with coarse fibres, dead leaves woven on to outside, c. 1 m above ground in horizontal fork of sapling; contained 2 eggs.

Movements. Presumably resident.

Status and Conservation. Not globally threatened. Apparently uncommon, but very easily overlooked in forest understorey. Very local in occurrence throughout range; in Venezuela, for example, recorded only from a few sites on lower R Caura and two places on middle R Paragua, with single record of subadult male in NW Amazonas (c. 20 km E of Puerto Ayacucho). Occurs in a number of protected areas, including Maracá Ecological Station (Roraima), Chapada dos Guimarães National Park and Rio Cristalino Forest Reserve (Mato Grosso), all in Brazil, Tambopata-Candamo Reserved Zone and Amazonia Lodge, in Peru, and also Noel Kempff Mercado National Park, in Bolivia.

Bibliography. Acheson & Davis (2001), Allen (1995), Bates & Parker (1998), Bradshaw & Kirwan (1995), Dubs (1992), Forrester (1993), Hellmayr (1929), Hilty (2003), Meyer de Schauensee (1982), Novaes (1978a), Oren & Parker (1997), Parker & Hoke (2002), Parker, Donahue & Schulenberg (1994), Parker, Kratter & Wust (1994), Parker, Schulenberg & Wust (1994), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Sick (1967, 1993, 1997), Stotz *et al.* (1996), Terborgh *et al.* (1984), Traylor (1958), Willis & Oniki (1990), Zimmer & Hilty (1997).

34. Western Striped Manakin

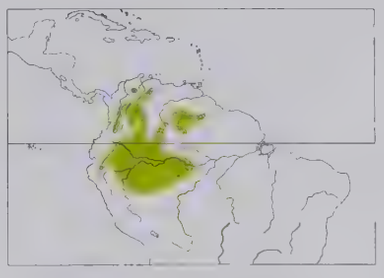
Machaeropterus striolatus

French: Manakin strié **Spanish**: Saltarín Rayado Occidental
German: Westliche Streifenbauchpipra
Other common names: Striped Manakin (when treated as conspecific with *M. regulus*)

Taxonomy. *Pipra striolata* Bonaparte, 1838, lower River Javarí, west Brazil.
Formerly treated as conspecific with *M. regulus*, but differs markedly in voice and, to lesser extent, in plumage. Five subspecies recognized.

Subspecies and Distribution.

M. s. zulianus Phelps, Sr & Phelps, Jr, 1952 - NW Venezuela (Zulia, and NW Barinas S to Táchira).



M. s. obscurostriatus Phelps, Sr & Gilliard, 1941 - W Trujillo and W Mérida, in NW Venezuela.

M. s. antioquiae Chapman, 1924 - W & C Colombia.

M. s. striolatus (Bonaparte, 1838) - E Colombia, E Ecuador, NE Peru (S to N Ucayali) and adjacent W Brazil (E to region of R Urucu, in C Amazonas).

M. s. aureopectus Phelps, Sr & Gilliard, 1941 - SE Venezuela and adjacent W Guyana.

Descriptive notes. 9-9·5 cm; 9·4 g. Male nominate race is olive above, with red cap and nape; secondaries stiffened and enlarged, with white tips; tail also stiffened, with thick rachi; throat whitish; rest of underparts reddish-chestnut, redder on chest side, with whitish shaft streaks; iris dark red-brown; upper mandible blackish, lower mandible paler; legs purplish-flesh. Differs from *M. regulus* in darker-looking underparts, reddish colour on chest. Female lacks red on head, is entirely olive above, dingy whitish below, breast and sides pale olive with fine whitish streaks, breast side tinged brownish. Juvenile resembles female. Races vary mainly in darkness and width of streaking below on male, also colour of staining across upper breast: *antioquiae* is similar to nominate but white streaks below on average broader, also male crown darker or duller, upperparts more yellow-tinged; *zulianus* has breast stained crimson; *obscurostriatus* has white shaft streaks below broader, feather edgings darker, only few crimson streaks, rump tinged yellowish; *aureopectus* is closest to previous but has distinct yellowish breastband. Voice. Male advertising call evidently geographically variable, in Venezuela a soft, sharply enunciated "pik-sink", in E Colombia a fast series of high-pitched notes followed by short buzz, "whit whit whit whit skeeezz", in W Brazil (upper R Juruá) a soft, insect-like "whoo-cheet"; during display, whirring sound produced by modified secondaries.

Habitat. Inhabits humid forest and mature secondary woodland, occasionally venturing out to forest borders. Lowlands to middle elevations, to 1500 m in Colombia; 100-1200 m (mostly above 300 m) in Venezuela, and to c. 1100 m in S Ecuador (but below 700 m in N) and to 1300 m in Peru.

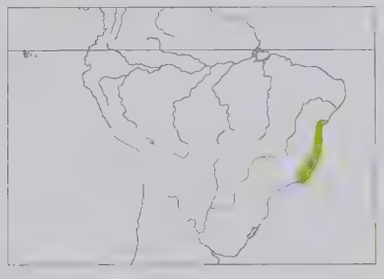
Food and Feeding. Small fruits and insects, taken in rapid aerial sallies.

Breeding. No information on season or nest. Male displays at small "exploded" lek, probably within hearing distance of others; when female present, makes vertical jumps with vibrating wings, may also revolve rapidly around and beneath perch.

Movements. Resident.

Status and Conservation. Not globally threatened. Generally uncommon to locally fairly common. Fairly common but very local in Venezuela, rare in Guyana; very local in Colombia; uncommon to fairly common but apparently local in Ecuador and Peru. Easily overlooked when not calling. Occurs in Tayrona National Park, in Colombia, and Podocarpus National Park, in Ecuador.

Bibliography. Agro & Ridgely (1998), Balchin & Toyne (1998), Best *et al.* (1997), Blake (1962), Butler (1979), Chapman (1917c), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Iafrancesco *et al.* (1987), Peres & Whittaker (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sick (1967, 1993, 1997), Whittaker & Oren (1999).



35. Eastern Striped Manakin

Machaeropterus regulus

French: Manakin rubis **Spanish**: Saltarín Rayado Oriental
German: Östliche Streifenbauchpipra
Other common names: Striped Manakin (when treated as conspecific with *M. striolatus*)

Taxonomy. *Pipra regulus* Hahn, 1819, Bahia, Brazil.
Formerly treated as conspecific with *M. striolatus*, but differs markedly in voice and, to lesser extent, in plumage; there is some evidence that it may be more closely related to *M. pyrocephalus*. Monotypic.

Distribution. SE coastal Brazil, from Bahia S to Rio de Janeiro.

Descriptive notes. 9-9·5 cm. Male is olive above, with red forehead to nape; secondaries stiffened and enlarged, with white tips; tail also stiffened, with thick rachi; throat whitish; underparts whitish, slight yellow wash on upper breast, feathers narrowly edged red-brown on outer sides; iris dark red-brown; upper mandible blackish, lower mandible paler; legs purplish-flesh. Differs from *M. striolatus* in having whiter underparts, no red on chest. Female is similar to male but no red on head, and dark streaks on underparts restricted to belly and, especially, flanks. Juvenile resembles female. Voice. Male advertising call a very fast metallic buzzing, shorter and repeated more quickly than call of *M. striolatus*.

Habitat. Humid lowland forest.

Food and Feeding. No details recorded.

Breeding. No information on season or nest. Male displays in presence of another, by hanging head downwards from side of thin vertical stem and turning very rapidly to and fro, also extends wings, fans and shakes tail, spreads crown feathers.

Movements. Presumably resident.

Status and Conservation. Not globally threatened. Very poorly known. Its population has undoubtedly been much reduced by extensive destruction of Atlantic coastal forest. Conservation status not officially assessed, as taxonomic status only recently upgraded to that of a full species. Should probably be categorized as Vulnerable.

Bibliography. Cracraft (1985), Forrester (1993), Hellmayr (1929), Mazar Barnett & Kirwan (1998a), Meyer de Schauensee (1982), Pacheco & Bauer (2001), Pearman (1994b), Ridgely & Tudor (1994), Sargeant & Wall (1996), Sick (1967, 1993, 1997), Stotz *et al.* (1996), Whittaker & Oren (1999).

36. Club-winged Manakin

Machaeropterus deliciosus

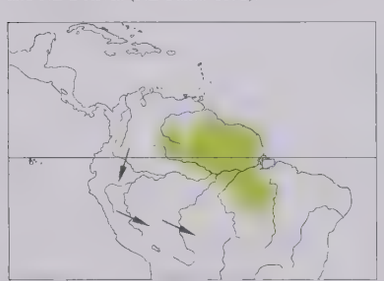
French: Manakin à ailes blanches **German**: Keulenschwingenpipra **Spanish**: Saltarín Alitorcido

Taxonomy. *Pipra deliciosa* P. L. Sclater, 1860, Nanegal, Pichincha, Ecuador.
Formerly placed in a monotypic genus *Allocotopterus* on basis of highly modified secondaries, but now considered better merged with present genus, other members of which (*M. pyrocephalus*, *M. striolatus*, *M. regulus*) exhibit similar, though less extreme, modifications. Monotypic.

On following pages: 37. Black Manakin (*Xenopipo atronitens*); 38. Jet Manakin (*Chloropipo unicolor*); 39. Olive Manakin (*Chloropipo uniformis*); 40. Green Manakin (*Chloropipo holochlora*); 41. Yellow-headed Manakin (*Chloropipo flavicapilla*); 42. Flame-crested Manakin (*Heterocercus linteatus*); 43. Yellow-crested Manakin (*Heterocercus flavivertex*); 44. Orange-crested Manakin (*Heterocercus aurantiivertex*).

Distribution. W slope of Andes in SW Colombia (S from Risaralda) and W Ecuador (S to Pichincha, also in El Oro and W Loja).

Descriptive notes. 9·5-10 cm; 1 female 12 g. Distinctive manakin, male with greatly modified secondaries. Male has scarlet forehead and crown, dusky eyestripe; rest of body mostly chestnut-brown, paler on head and throat, darker on belly, some white admixed on flanks; blackish rump and uppertail-coverts; scapulars, wings and tail black, wings with much white, especially on inner secondaries; secondaries peculiarly modified, progressively from outermost to S7, then decreasingly from S8 to S10, being thickened, twisted, and bent at tip, the most modified having hollow club-shaped end; iris dark brown; bill black; legs greyish-flesh, sometimes purplish. Female is olive above, face with cinnamon tinge, whitish throat, yellowish-olive breast and flanks, pale yellow belly. Juvenile resembles female. VOICE. Male call at lek a high-pitched "seet" or "seet-seet" followed by up to 8 loud, strident "keah!" notes; during display a mechanical wing noise, "tip-tip-beeuwww", final note with ringing quality, produced by vibration of hollow club-shaped tips of secondaries.
Habitat. Wet montane forest, especially where mossy, also mature secondary woodland. Mostly 600-1900 m, to 1600 m in Ecuador; locally lower in non-breeding season, down to 100 m in Ecuador.
Food and Feeding. Small berries and insects, plucked and taken from twigs and leaves in aerial sallies. Occasionally accompanies mixed-species flocks.
Breeding. Egg-laying in Mar-Aug in Colombia. Male displays solitarily, but often within hearing distance of others, on thin branch up to c. 7 m above ground, flutters wings rapidly downwards and then holds them raised high, producing mechanical sound described above. Nest a small cup of vegetable fibres, covered on outside with moss, slung in horizontal fork of shrub at 0·5-1·2 m above ground. Clutch 2 eggs; incubation and fledging periods not recorded.
Movements. Resident. Apparently seasonal altitudinal movements in Ecuador, descending to c. 100 m during non-breeding (dry) season.
Status and Conservation. Not globally threatened. Restricted-range species: present in Chocó EBA. Uncommon to fairly common but local, or very local, within relatively small range; occurs in Río Ñambí and La Planada Nature Reserves (Colombia). Has possibly extended its range in Ecuador; recorded since 1988 in El Oro (Buenaventura), where apparently absent previously. Dependent on conservation of adequate forest at upper tropical and subtropical levels.
Bibliography. Allen (1998), Best *et al.* (1997), Bostwick (2000), Bostwick & Prum (1998), Butler (1979), Chapman (1917c), Cracraft (1985), Hellmayr (1929), Hilty (1997), Hilty & Brown (1986), Meyer de Schauensee (1982), Orejuela *et al.* (1982), Ortiz & Carrión (1991), Ramírez & Arias (1995), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Snow (1975a), Stotz *et al.* (1996), Willis (1966).



Genus *XENOPIPO* Cabanis, 1847

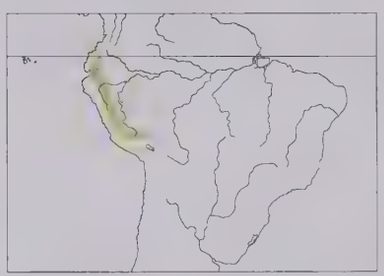
37. **Black Manakin**

Xenopipo atronitens

French: Manakin noir **German**: Schwarzpipra **Spanish**: Saltarín Negro

Taxonomy. *Xenopipo atronitens* Cabanis, 1847, Guyana.
Genus closely related to *Chloropipo*, which sometimes merged with it, but the single species in present genus differs in being much more vocal. Monotypic.
Distribution. Extreme E Colombia, S & SE Venezuela, the Guianas, and Amazonian Brazil (R Negro drainage E to Amapá and R Araguaia); isolated records in E Peru (Loreto, Madre de Dios) and NE Bolivia (NE Santa Cruz).

Descriptive notes. 12-13 cm; 12·5-18 g. Relatively long-tailed manakin with rather heavy bill, recalling a tyrant-flycatcher (Tyrannidae), tanager (Thraupidae) or even small finch (Fringillidae). Male is glossy black, slightly duller and browner on wings and tail; iris dark brown; bill pale bluish-grey; legs dark olive-grey. Female is dark olive above, yellowish-olive below, throat greyish, upper mandible blackish. Juvenile apparently undescribed. VOICE. Calls numerous and varied, loud and sharp; include "skee! kip-kip-kip-krrr", with many variations, and a dry, rattling "trrrrrrrrrup".
Habitat. Scrubby savanna woodland and thickets, stunted *várzea* forest, also gallery woodland; frequently in areas with white sandy soils, almost exclusively so in Venezuela. To 1200 m, mostly below c. 700 m.
Food and Feeding. Small fruits and insects, taken in aerial sally. Regularly accompanies mixed-species foraging flocks.
Breeding. Not recorded. Male display unspectacular, no more than calling and chasing.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally considered to be locally common to fairly common in suitable habitat, but patchily distributed. Rare and local in heavily forested regions; thus only three records from French Guiana, although rather common in adjacent Surinam. Isolated records from SE Peru (Pampas del Heath, in Madre de Dios) and NE Bolivia (Serranía de Huanchaca, in NE Santa Cruz) suggest that range is probably more extensive than is currently realized.
Bibliography. Bangs & Penard (1918), Bates & Parker (1998), Borges *et al.* (2000), Friedmann (1948), Graham *et al.* (1980), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Oren & Parker (1997), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1960, 1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Zimmer & Hilty (1997).



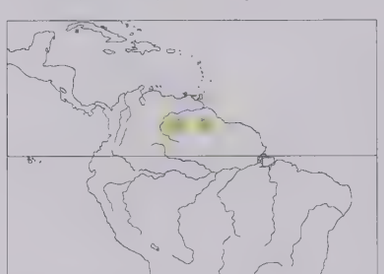
Genus *CHLOROPIPO* Cabanis & Heine, 1859

38. **Jet Manakin**

Chloropipo unicolor

French: Manakin unicolore **German**: Atlaspipra **Spanish**: Saltarín Azabache

Taxonomy. *Chloropipo unicolor* Taczanowski, 1884, Amable María, Peru.
Genus closely related to *Xenopipo* and sometimes merged with it, but differs in having far less extensive vocal repertoire. Monotypic.
Distribution. Upper tropical zone of E slope of Andes in Ecuador (S from W Napo) and Peru (S to Puno).



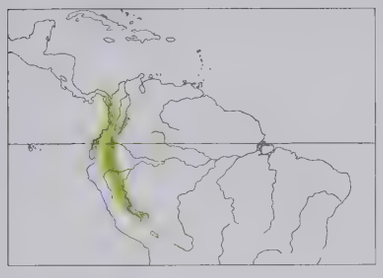
Descriptive notes. 12 cm; 15·5 g. Male is black, with white underwing-coverts; iris dark brown; bill bluish-grey to grey, or darker with pale base of lower mandible; legs dark olive-grey to pinkish-grey. Female is dark olive with vague pale eyering, greyish on throat and belly. Juvenile undescribed. VOICE. Call a down-slurred whistle, "peeeeer".
Habitat. Montane forest; recorded at elevations of 1450-1700 m in Ecuador, and 930-1900 m in Peru.
Food and Feeding. No information.
Breeding. Not recorded.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Very poorly known. Apparently uncommon to fairly common, but inconspicuous and rarely observed; in some areas not infrequently captured in mist-nets.
Bibliography. Best *et al.* (1997), Clements & Shany (2001), Cracraft (1985), Hellmayr (1929), Mee *et al.* (2002), Meyer de Schauensee (1982), Parker *et al.* (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Schulenberg & Wust (1997), Schulenberg *et al.* (2001), Stotz *et al.* (1996).

39. **Olive Manakin**

Chloropipo uniformis

French: Manakin olive **German**: Tepuipipra **Spanish**: Saltarín Oliváceo

Taxonomy. *Chloropipo uniformis* Salvin and Godman, 1884, Mount Roraima, Venezuela.
Genus closely related to *Xenopipo* and sometimes merged with it, but differs in having far less extensive vocal repertoire. Two subspecies recognized.
Subspecies and Distribution.
C. u. duidae Chapman, 1929 - cerros Duida and Sipapo, in Amazonas, SC Venezuela.
C. u. uniformis Salvin & Godman, 1884 - SE Venezuela (various mountains in S Bolívar), adjacent N Brazil (Cerro Uei) and W Guyana.



Descriptive notes. 13·5 cm; male 18-21 g, female 16·5-21 g. Rather long-winged manakin with relatively long and narrow tail. Plumage is rather dark olive, slightly paler on throat, and slightly paler with yellowish cast on belly and on indistinct eyering; underwing-coverts whitish; iris, bill and legs dark. Sexes similar. Juvenile resembles adult. Race *duidae* is slightly smaller and brighter than nominate. VOICE. Advertising call a clear, rising whistle, "preeeeeeeeé", penetrating but not loud.
Habitat. Stunted montane woodland and humid forest; 800-2100 m. Most frequent in areas dominated by melastomes (Melastomataceae).
Food and Feeding. Small fruits; presumably also insects.
Breeding. Not recorded.
Movements. Resident. Possibly some seasonal elevational movements.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Fairly common to uncommon, but easily overlooked; relatively quiet. Occurs in Canaíma National Park, in Venezuela.
Bibliography. Chapman (1931), Forrester (1993), Gilliard (1941), Hellmayr (1929), Hilty (2003), Mayr & Phelps (1967), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Rodner *et al.* (2000), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996).

40. **Green Manakin**

Chloropipo holochlora

French: Manakin vert **German**: Grünpipra **Spanish**: Saltarín Verde
Other common names: Lita Manakin (*suffusa*, *litae*)

Taxonomy. *Chloropipo holochlora* P. L. Sclater, 1888, "Bogotá" = east slope of Andes in Bogotá area, Colombia.
Genus closely related to *Xenopipo* and sometimes merged with it, but differs in having far less extensive vocal repertoire. Races W of Andes (*litae* and, possibly inseparable from it, *suffusa*) may represent a separate species, but further study is required. Four subspecies currently recognized.
Subspecies and Distribution.
C. h. suffusa Griscom, 1932 - E Panama (San Blas, Darién) and adjacent NW Colombia.
C. h. litae Hellmayr, 1906 - W of Andes in W Colombia and W Ecuador (S mainly to Pichincha).
C. h. holochlora P. L. Sclater, 1888 - E slope of Andes and adjacent lowlands from Colombia (S from Meta) S to C Peru.
C. h. viridior Chapman, 1924 - E slope of Andes in SE Peru.

Descriptive notes. 11·5-12·5 cm; 11-18·7 g. Nominate race is bright moss-green above, with an indistinct pale eyering, olive below, with pale yellow belly; iris dark brown; upper mandible blackish, lower mandible grey; legs greyish. Sexes similar. Juvenile apparently undescribed. Race *viridior* is on average larger than nominate, brighter above, with more extensive and deeper yellow below; *suffusa* and *litae* are markedly duller olive above, also on throat and breast, contrasting more with pale yellow belly. Voice. Generally silent; only a single harsh "arrrn", apparently in aggression, and soft sputtering calls recorded.
Habitat. Humid and wet forest in lowlands and foothills; mainly hilly *terra firme* forest in E Ecuador and Peru. To 1300 m, locally to 1500 m.
Food and Feeding. No detailed information. Occasionally seen at fruiting trees; perhaps more insectivorous than typical piprids. Sometimes found in mixed-species foraging flocks.
Breeding. Egg-laying recorded in Jun and nestling in mid-Aug in Panama; record of laying in Nov in Peru. Nest a shallow cup of rootlets, with moss and dead leaves hanging from bottom, 1·6-2 m over forest stream in fork of slender branch, attached by cobwebs, rootlets and moss. No other information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Little known. Apparently uncommon to locally fairly common, but easily overlooked; in some areas quite often captured in mist-nets. Was possibly more common and more widespread in W Ecuador prior to extensive deforestation; specimen captured in NC Los Ríos in 1950 and one mist-netted as far S as NW Azuay in 1991. Occurs in Río Nambí Natural Reserve, in Colombia.
Bibliography. Allen (1998), Angehr & Aucca (1997), Balchin & Toyne (1998), Best *et al.* (1997), Butler (1979), Chapman (1917c), Christian (2001), Cracraft (1985), Delgado (1985), Eisenmann (1955), Haffer (1975), Hellmayr (1929), Hilty & Brown (1986), Mee *et al.* (2002), Meyer de Schauensee (1982), Parker (1992c, 1997), Parker & Wust (1994), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Stotz *et al.* (1996), Wetmore (1972).

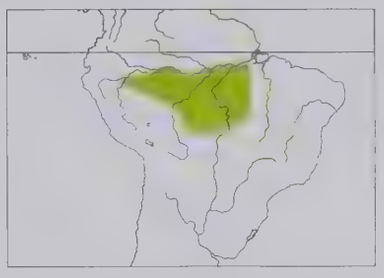
41. **Yellow-headed Manakin**

Chloropipo flavicapilla

French: Manakin à tête jaune **German**: Goldkappenpipra **Spanish**: Saltarín Amarillo

Taxonomy. *Pipra flavicapilla* P. L. Sclater, 1852, Nouvelle-Grenade [= Colombia; presumably from Bogotá area].
Genus closely related to *Xenopipo* and sometimes merged with it, but differs in having far less extensive vocal repertoire. Monotypic.
Distribution. Subtropical zone of Andes locally in Colombia (W range in Valle and Cauca, W slope of C range in Antioquia and Huila, possibly also E slope in W Putumayo) and N & C Ecuador (E slope in W Napo and Tungurahua).

Descriptive notes. 12-13 cm; 16·8-19·5 g. Male has golden-yellow crown and nape, bright olive upperparts; face, throat and breast paler and yellower, belly pale yellow; underwing-coverts white (may be visible at bend of wing); iris pale orange to red; upper mandible blackish, lower mandible paler bluish-grey; legs grey. Female is similar to male, but head and breast duller, less yellow. Juvenile resembles female but duller. Voice. Not recorded; apparently generally silent.
Habitat. Humid montane forest and mature secondary woodland; 1200-2400 m in Colombia, c. 1500-2100 m in Ecuador.
Food and Feeding. Little information; diet mainly fruits, probably including those of the rubiaceous genus *Palicourea*. Occasionally observed in mixed-species flocks.
Breeding. Female feeding dependent young in May and female with brood patch in Sept in Colombia. No other information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Colombian Inter-Andean Slopes EBA, Chocó EBA and Ecuador-Peru East Andes EBA. Poorly known and few recent records; apparently rare to uncommon, but probably easily overlooked. Only three records from Ecuador, one in 19th century (in Tungurahua) and two during Nov 1990 to Jan 1991 (both in W Napo). Certainly vulnerable to deforestation, which has been extensive in much of this species' range; a large percentage of its habitat has already been lost to agriculture. Further fieldwork and research required in order to establish its true conservation status, which may merit upgrading to the category of Vulnerable.
Bibliography. Best *et al.* (1997), Butler (1979), Chapman (1917c), Granizo *et al.* (1997), Hellmayr (1929), Hilty (1985), Hilty & Brown (1986), Iafrancesco *et al.* (1987), López *et al.* (2000), Mazar Barnett & Kirwan (2002b), Meyer de Schauensee (1982), Miller (1963), Negret (2001), Pacheco (2002b), Peña & Weber (2000), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg (2002), Stattersfield & Capper (2000), Stotz *et al.* (1996).



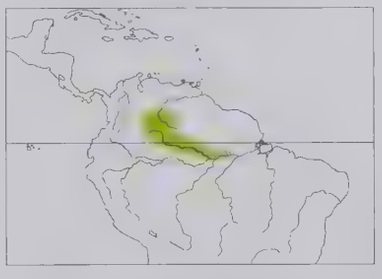
Genus *HETEROCERCUS* P. L. Sclater, 1862

42. **Flame-crested Manakin**

Heterocercus linteatus

French: Manakin à moustaches **German**: Schwarzkopfpipra **Spanish**: Saltarín Crestirrojo
Other common names: Flame-crowned Manakin; Anomalous Manakin ("*Pipra anomala*")

Taxonomy. *Elaenia linteata* Strickland, 1850, Borba, River Madeira, Brazil.
Genus has been suggested as being closest to *Pipra* on basis of syringeal details, also as possibly sister to *Corapipo* on basis of display behaviour and nest architecture. Forms a superspecies with *H. flavivertex* and *H. aurantiivertex*, and all three sometimes considered conspecific. Status of a fourth described taxon, *H. luteocephalus* ("Golden-crested Manakin"), known only from unique type (now lost or destroyed) from unknown locality, considered doubtful, probably of hybrid origin. Present species has apparently hybridized with *Pipra aureola* (hybrid form described as "*Pipra anomala*"). Monotypic.
Distribution. NE Peru (E Loreto), C Brazil S of Amazon (E to R Xingu drainage and SE Mato Grosso) and extreme NE Bolivia; also isolated population in SE Peru (close to Puerto Maldonado, in SE Madre de Dios).



Descriptive notes. 14 cm; 20-24 g. Distinctive and unusual manakin with graduated tail (outer rectrices shortest), silky long throat feathers, relatively long and narrow bill. Male has black head, red coronal stripe (often concealed); otherwise, dark olive above and on flanks, white throat with elongated lateral feathers, sooty-olive band across chest, deep chestnut on breast, becoming cinnamon-rufous downwards; iris dark brown; bill and legs dark. Differs from congeners in darker colour above, red on crown. Female resembles male, but no red on crown, head concolorous with dark olive back, duskier on face, throat grey, flanks greyish-olive, rest of underparts cinnamon-buff, wings shorter. Juvenile apparently undescribed. Voice. Displaying male calls loudly, but call not described.
Habitat. Seasonally flooded forest (*várzea*) and riparian woodland; to c. 500 m.
Food and Feeding. Small fruits, insects and spiders taken. No other details.
Breeding. Not recorded. Male displays with others, flares white throat feathers, chases rivals. Nothing else known.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Generally uncommon; locally numerous, as in parts of Brazil (e.g. SE Mato Grosso). Very few records from Peru. Despite its wide range, this is a little-known species. Known to occur in Amazônia (Tapajós) National Park, in Brazil, and Noel Kempff Mercado National Park, in Bolivia.
Bibliography. Bates & Parker (1998), Dubs (1992), Forrester (1993), Gyldenstolpe (1950), Hellmayr (1929), Hennessey, Herzog & Sagot (2003), Meyer de Schauensee (1982), Parker, Schulenberg & Wust (1994), Pinto (1948), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1960, 1967, 1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Williams (1995a).

43. **Yellow-crested Manakin**

Heterocercus flavivertex

French: Manakin à bandeau jaune **German**: Grauwangenpipra **Spanish**: Saltarín Crestiamarillo
Other common names: Yellow-crowned Manakin

Taxonomy. *Heterocercus flavivertex* Pelzeln, 1868, Marabitanas, Rio Negro, Brazil.
Genus has been suggested as being closest to *Pipra* on basis of syringeal details, also as possibly sister to *Corapipo* on basis of display behaviour and nest architecture. Forms a superspecies with *H. linteatus* and *H. aurantiivertex*, and all three sometimes considered conspecific. Status of a fourth described taxon, *H. luteocephalus* ("Golden-crested Manakin"), known only from unique type (now lost or destroyed) from unknown locality, considered doubtful, probably of hybrid origin. Monotypic.
Distribution. E Colombia, SW Venezuela (extreme SE Apure, Amazonas), and Brazil N of Amazon (R Negro drainage E to W Pará).

Descriptive notes. 14 cm; 21 g. Distinctive and unusual manakin with graduated tail (outer rectrices shortest), silky long throat feathers, relatively long and narrow bill. Male has golden-yellow coronal patch (often concealed), rest of head and entire upperparts dark olive, face slaty-coloured; white throat with elongated lateral feathers, sooty-olive band across chest, deep chestnut on breast, becoming paler cinnamon-rufous below, flanks olive; iris dark brown; bill and legs dark; tongue and gape bright yellow (conspicuous when making advertising call). Differs from *H. linteatus* in having yellow on crown, head concolorous with somewhat paler upperparts. Female resembles male, but no yellow on crown, has grey throat, cinnamon-buff underparts, shorter wings; differs from female *H. linteatus* in slightly brighter upperparts, darker grey face. Immature male resembles female. Voice. Male advertising call a loud, whistled "weeee-pítch-ooo", lasting c. 3 seconds, with punctuated or hiccuping cadence; series of chattering "weer-weer-weer" in aggressive interactions; emphatic "chip" in display-flight from perch, and a "whoosh", probably of mechanical origin.
Habitat. Seasonally flooded forest (*várzea*) and adjacent scrubby woodland, seasonally flooded riparian woodland along black-water streams and oxbow lakes; to c. 300 m.
Food and Feeding. Small fruits and insects. Apparently more insectivorous than typical manakins, this possibly associated with longer, narrower bill. Insects taken from branches and leaves, usually in aerial sallies, rarely when perched. Sometimes briefly joins small mixed-species foraging flocks.
Breeding. Breeds in Feb-May (relatively dry season N of Amazon) in Venezuela. Male defends display territory, performs various flight displays, including rising above canopy, also flies rapidly through forest in presumed pursuit of rivals; courtship includes forward-bending while flaring throat feathers, raising and spreading tail, quivering body and tail. Only one nest documented, in Apr, a hanging cup in the fork of a descending tree branch, 2 m above surface of stream; apparently of typical piprid construction but it was abandoned before completion. No other information available.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common in suitable habitat; occurs in Junglaven Camp, in Venezuela. The only detailed study suggests rather low level of population compared with better-known piprid species.

Bibliography. Forrester (1993), Friedmann (1948), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Novaes (1978a), Oren & Parker (1997), Peres & Whittaker (1991), Prum *et al.* (1996), Ridgely & Tudor (1994), Sargeant (1994), Stotz *et al.* (1996), Willard *et al.* (1991), Zimmer & Hilty (1997).

44. **Orange-crested Manakin**

Heterocercus aurantiivertex

French: Manakin à bandeau orange **Spanish**: Saltarín Crestinaranja
German: Orangescheitelpipra
Other common names: Orange-crowned Manakin

Taxonomy. *Heterocercus aurantiivertex* P. L. Sclater and Salvin, 1880, Sarayacu, Ecuador.
Genus has been suggested as being closest to *Pipra* on basis of syringeal details, also as possibly sister to *Corapipo* on basis of display behaviour and nest architecture. Forms a superspecies with *H. linteatus* and *H. flavivertex*, and all three sometimes considered conspecific. Status of a fourth described taxon, *H. luteocephalus* ("Golden-crested Manakin"), known only from unique type (now lost or destroyed) from unknown locality, considered doubtful, probably of hybrid origin. Monotypic.
Distribution. Locally in E Ecuador (Napo) and N Peru (SW Loreto).
Descriptive notes. 14 cm; 21-22 g. Distinctive and unusual manakin with graduated tail (outer rectrices shortest), silky long throat feathers, relatively long and narrow bill. Male has greyish-olive head with orange coronal patch (often concealed), dull olive upperparts and sides, greyish-white throat, uniform dull cinnamon-buff underparts; iris dark brown; bill and legs dark. Differs from *H. flavivertex* in having orange (less yellow) on crown, somewhat duller upperparts, greyer throat feathers not (or only slightly) elongated, paler and more uniform underparts. Female is like male but duller, without orange on crown, shorter wings; differs from females of congeners in plainer-headed appearance, paler dull cinnamon-buff underparts. Immature resembles female. Voice. Male advertising call a thin, meandering trill of variable length, 1-3 seconds; loud chatter in aggressive interactions; in rapid vertical descent above forest canopy a hissing sound, increasing in volume as bird's speed increases (and almost certainly made by wings), followed by explosive "pop" (perhaps made by wings and/or tail) at end of descent.

Habitat. Seasonally flooded forest (*várzea*), mainly in black-water drainages; to 300 m.
Food and Feeding. Fruits and insects; small fruits of figs (*Ficus*) an important component of diet. Food items plucked or snatched in aerial sallies.
Breeding. Egg-laying recorded in Feb in N Peru. Male defends display "court" in forest; also has spectacular aerial display, flies steeply upwards in decreasingly narrow spirals to 60-100 m above canopy, then plummets down, gaining momentum with rapid wingbeats for 15-20 m, then continues descent on partially closed wings until 2-3 m above canopy, where abruptly changes direction, and finally flies in wide horizontal arc above canopy before entering trees at great speed and returning to its court. One active nest found (Peru), a shallow cup of vegetable fibres, so thinly woven that eggs visible from below, attached by spider web to supporting branch within fork of thin horizontal branch c. 4 m above small stream; contained 2 eggs; incubation and fledging periods not known.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Upper Amazon-Napo Lowlands EBA. Known from relatively few localities. Formerly considered rare, but recent study has shown it to be reasonably common in preferred habitat. In Ecuador, recently reported at various sites in region of R Napo and R Aguarico, including e.g. Sacha Lodge, Yuturi Lodge and La Selva; also observed more regularly in NE Peru. Range may be considerably wider than the few records indicate; possibly occurs in S Colombia (Putumayo).

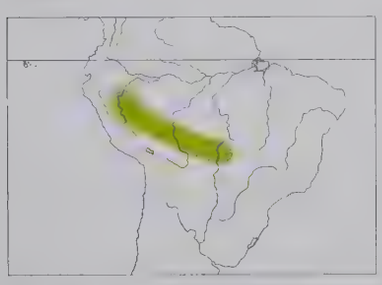
Genus *NEOPELMA* P. L. Sclater, 1861

45. Saffron-crested Tyrant-manakin

Neopelma chrysocephalum

French: Manakin à panache doré **German**: Goldscheitelpipra **Spanish**: Saltarín Coronigualdo
Other common names: Saffron-crested Manakin

Taxonomy. *Heteropelma chrysocephalum* Pelzeln, 1868, San Carlos, Río Negro, Venezuela.
Systematic position of genus doubtful; possibly closest to *Tyranneutes*, and both genera almost certainly only distantly related to the typical piprids; probably closer to the Tyrannidae but traditionally included in present family, where retained pending further study. Present species considered to form a superspecies with its four congeners. Monotypic.
Distribution. Extreme E Colombia (Vaupés), S Venezuela, the Guianas and N Brazil (mainly R Negro drainage and extreme N Amapá); also NE Peru (SW of Iquitos).



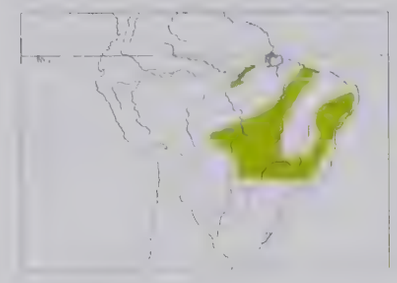
Descriptive notes. 13 cm; male 14·4-16·3 g. Dull, rather tyrannid-like manakin with relatively long bill and tail. Has rich golden-yellow median crownstripe (partly concealed) extending to nape, accentuated by dark greyish-olive crown side; upperparts olive-green, wings and tail tinged brownish; dull olive-grey throat, greyish-olive upper breast, contrastingly yellow lower breast and belly; iris pale orange to pale yellowish-white or whitish; bill and legs greyish. Sexes alike. Juvenile undescribed. Voice. Male advertising call a nasal, twanging "wrraaaaang, wrang-wrang-wrang", of variable length, also a repeated, nasal, squeaky "skeenh!".
Habitat. Woodland, including scrubby woodland, and forest in savanna areas, especially in places with thin-stemmed brushwood; found primarily in areas with sandy soils. To 700 m.
Food and Feeding. Small fruits and insects, latter including hymenopterans and small beetles (Coleoptera). Fruits taken by hover-gleaning; insects snatched in short, rapid sally to foliage, less often to branches or trunks.
Breeding. Male with greatly enlarged gonads in mid-May in Peru. Male displays solitarily, well away from but probably within hearing distance of one or more others; makes short upward leaps of 6-8 cm from thin horizontal perch, holding crown feathers raised and spread, while emitting twanging call; also adopts horizontal posture on perch while wing-flicking and neck-twitching, exhibiting golden crest. Nest and eggs not recorded.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally uncommon; locally numerous in areas of suitable habitat. Common in limited range in Peru, where only recently discovered. Rather infrequently observed, but thought to be probably more numerous than is suggested by recorded sightings. Occurs at Junglaven Lodge, in Venezuela.
Bibliography. Bangs & Penard (1918), Cohn-Haft *et al.* (1997), Davis (1949b), Forrester (1993), Friedmann (1948), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Novaes (1978a), Ridgely & Tudor (1994), Sick (1967), Snow (1963c), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Willard *et al.* (1991).

46. Sulphur-bellied Tyrant-Manakin

Neopelma sulphureiventer

French: Manakin à ventre jaune **Spanish**: Saltarín Ventrisulfúreo
German: Westliche Gelbbauchpipra
Other common names: Sulphur-bellied Manakin

Taxonomy. *Scotothorus sulphureiventer* Hellmayr, 1903, Villa Bella de Mato Grosso, Mato Grosso, Brazil.
Systematic position of genus doubtful; possibly closest to *Tyranneutes*, and both genera almost certainly only distantly related to the typical piprids; probably closer to the Tyrannidae but traditionally included in present family, where retained pending further study. Present species considered to form a superspecies with its four congeners. Monotypic.
Distribution. E & SE Peru, N Bolivia (S to Cochabamba and N Santa Cruz) and adjacent parts of W Brazil.



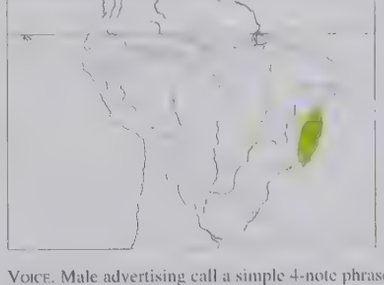
Descriptive notes. 13-13·5 cm; male 15-19·4 g, female 14-16 g. Dull, rather tyrannid-like manakin with relatively long bill and tail. Has pale sulphur-yellow median crownstripe (partly concealed), plain olive-green upperparts, slightly browner on wings and tail; dull greyish-white throat, greyish-olive upper breast, clear pale sulphur-yellow lower breast and belly; iris pale greyish to creamy or orange-brown; bill brownish; legs greyish. Sexes alike. Juvenile undescribed. Voice. Series of 3-4 doubled, hoarse, almost frog-like scolding notes, probably male advertising call.
Habitat. Humid forest, especially riverine forest with dense undergrowth, often where bamboo thickets present; to 450 m.
Food and Feeding. Limited data from stomach contents indicate mainly insectivorous diet; some fruits.
Breeding. No information. Jun, Aug and Oct specimens from Bolivia were not in breeding condition.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Poorly known species. Appears to be uncommon and local. An inconspicuous and shy inhabitant of dense undergrowth, hence is easily overlooked. Occurs in Manu National Park and Biosphere Reserve, in Peru.
Bibliography. Allen (1995), Angehr & Aucca (1997), Bates & Parker (1998), Craeraft (1985), Dubs (1992), Forrester (1993), Hellmayr (1929), Hennessey, Herzog & Sagot (2003), Mazar Barnett, Kirwan & Tobias (1998a), Meyer de Schauensee (1982), Parker & Hoke (2002), Remsen *et al.* (1988), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Sick (1993, 1997), Stotz *et al.* (1996), Terborgh *et al.* (1984).

47. Pale-bellied Tyrant-manakin

Neopelma pallescens

French: Manakin à ventre blanc **German**: Rahmbauchpipra **Spanish**: Saltarín Ventriblanco
Other common names: Pale-bellied Manakin

Taxonomy. *Tyrannula pallescens* Lafresnaye, 1853, Bahia, Brazil.
Systematic position of genus doubtful; possibly closest to *Tyranneutes*, and both genera almost certainly only distantly related to the typical piprids; probably closer to the Tyrannidae but traditionally included in present family, where retained pending further study. Present species considered to form a superspecies with its four congeners. Monotypic.
Distribution. E, C & S Brazil (on both sides of lower Amazon and lower R Tapajós, from Maranhão SW to S Mato Grosso, and from Rio Grande do Norte S to W São Paulo) and extreme NE Bolivia (Serranía de Huanchaca, in NE Santa Cruz).



Descriptive notes. 14 cm; 16-20·5 g. Dull, rather tyrannid-like manakin with relatively long bill and tail. Has large bright yellow median crown patch, accentuated by dusky lateral borders; otherwise, plain olive above; whitish throat faintly streaked grey, breast pale olivaceous grey, belly pale creamy whitish; iris pale greyish-mauve; bill and legs brownish to greyish. Distinguished from congeners by larger size, whiter belly. Sexes alike. Juvenile undescribed. Voice. Male advertising call a soft, low, nasal "wraah, wra-wra".
Habitat. Deciduous woodland and gallery woodland, often in areas where heavy growth of vines present; to 700 m.
Food and Feeding. Diet apparently predominantly insects, as contents of four stomachs consisted entirely of insect remains; fruits of melastomes (of genus *Miconia*) also consumed.
Breeding. Carrying of nest material observed in early Nov in E Brazil (S Ceará). Male displays solitarily from low branch; from time to time makes small upward leap, often landing with reversed orientation. No other information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Not well known. Appears to be uncommon and local, but is inconspicuous and easily overlooked; true extent of range perhaps incompletely known. Occurs in Chapada Diamantina National Park, in Brazil (Bahia), and Noel Kempff Mercado National Park, in Bolivia.
Bibliography. Bates & Parker (1998), Bates *et al.* (1998), Dubs (1992), Forrester (1993), Hellmayr (1929), Hennessey, Herzog & Sagot (2003), Meyer de Schauensee (1982), do Nascimento *et al.* (2000), Pinto & Camargo (1961), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1960, 1967, 1993, 1997), de Souza (2000), Stotz *et al.* (1996), Willis & Oniki (1990).

48. Wied's Tyrant-manakin

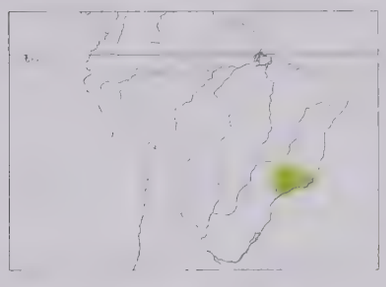
Neopelma aurifrons

French: Manakin tyran **German**: Östliche Gelbbauchpipra **Spanish**: Saltarín de Wied
Other common names: Wied's Manakin

Taxonomy. *Muscicapa aurifrons* Wied, 1831, Camamú, south Bahia, Brazil.
Systematic position of genus doubtful; possibly closest to *Tyranneutes*, and both genera almost certainly only distantly related to the typical piprids; probably closer to the Tyrannidae but traditionally included in present family, where retained pending further study. "*N. inornata*" is a synonym of present species. Considered to form a superspecies with its four congeners; until recently was treated as conspecific with *N. chrysolophum*, but the two differ ecologically and vocally, and overlap geographically to a limited extent. Monotypic.
Distribution. Coastal E Brazil, from S Bahia S to E Minas Gerais, Espírito Santo and Rio de Janeiro.

Descriptive notes. 13 cm. Dull, rather tyrannid-like manakin with relatively long bill and tail. Has rather small yellow to orange-yellow median crownstripe (absent or vestigial in a minority of individuals, with some yellow only on feather bases of central crown); rest of head and entire upperparts plain olive-green; dull greyish-white throat, greyish-olive upper breast, pale sulphur-yellow lower breast and belly; iris pale greyish-mauve; bill and legs greyish. Distinguished from similar *N. chrysolophum* by much shorter tail, appreciably longer wing and bill, less conspicuous yellow crownstripe. Sexes alike. Juvenile undescribed. Voice. Male advertising call a simple 4-note phrase, repeated at regular intervals, shorter and simpler than that of *N. chrysolophum*.
Habitat. Undisturbed or lightly disturbed forest, generally in interior parts, but sometimes foraging near edges. Sea-level to c. 1000 m.

On following pages: 49. Serra Tyrant-manakin (*Neopelma chrysolophum*); 50. Dwarf Tyrant-manakin (*Tyranneutes stolzmanni*); 51. Tiny Tyrant-manakin (*Tyranneutes virescens*); 52. Grey-headed Piprites (*Piprites griseiceps*); 53. Wing-barred Piprites (*Piprites chloris*); 54. Black-capped Piprites (*Piprites pileata*); 55. Broad-billed Sapayoa (*Sapayoa aenigma*); 56. Varzea Mourner (*Schiffornis major*); 57. Thrush-like Mourner (*Schiffornis turdina*); 58. Greenish Mourner (*Schiffornis virescens*).



Food and Feeding. Primarily small fruits, also insects; one individual seen to take a stick-insect (Phasmida). Items plucked or snatched from foliage, mostly within c. 7 m of ground, in short-range flight sallies and hovers.
Breeding. Male sings from thin horizontal branch in shaded open area of understorey, generally 3·5-7 m above ground. Nest-site possibly beneath bank or under hanging roots. No other information.
Movements. Presumed resident.
Status and Conservation. ENDANGERED. Rare, and recorded from few sites; very few records since 1990. Last recorded in Bahia in 1990, in Chapada Diamantina National Park; no recent records from Minas Gerais. Recent observations from three localities in Espírito Santo, including Augusto Ruschi Biological Reserve; uncommon in Sooretama Biological Reserve in 1981, but seen there only once since. Known from a single locality in Rio de Janeiro. Formerly more widespread within its total E Brazilian range; population greatly reduced by extensive destruction of lowland Atlantic Forest. Conservation priorities include establishment of effective protection of the small population found NE of Rio de Janeiro city; field surveys also required in order to determine whether the species survives at other sites within its range.
Bibliography. Cracraft (1985), Forrester (1993), Hellmayr (1929), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Sargeant & Wall (1996), Sick (1960, 1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Whitney *et al.* (1995).

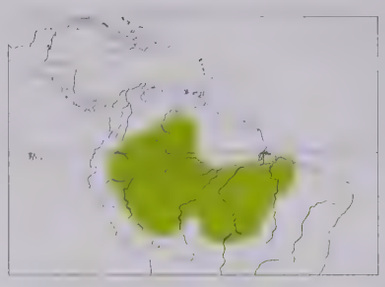
49. Serra Tyrant-manakin

Neopelma chrysolophum

French: Manakin de Serra do Mar **Spanish**: Saltarín de Serra do Mar
German: Goldhaubenpipra
Other common names: Serra do Mar Tyrant-manakin

Taxonomy. *Neopelma aurifrons chrysolophum* Pinto, 1944, no locality = Minas Gerais, Brazil.
Systematic position of genus doubtful; possibly closest to *Tyranneutes*, and both genera almost certainly only distantly related to the typical piprids; probably closer to the Tyrannidae but traditionally included in present family, where retained pending further study. Present species originally named as *Muscicapa luteocephala*, but that name invalid, as preoccupied. Considered to form a superspecies with its four congeners; previously treated as conspecific with *N. aurifrons*, but the two differ ecologically and vocally, and overlap geographically to a limited extent. Monotypic.
Distribution. Coastal SE Brazil, from EC Minas Gerais S to extreme S São Paulo and probably also adjacent E Paraná.

Descriptive notes. 13·5 cm; 13·5-14·9 g. Dull, rather tyrannid-like manakin with long tail. Has conspicuous yellow crown patch, rest of head and upperparts plain olive-green; dull greyish-white throat, greyish-olive upper breast, pale sulphur-yellow lower breast and belly; iris pale greyish-mauve; bill and legs greyish. Distinguished from similar *N. aurifrons* by noticeably longer tail, shorter bill and wing, often larger coronal patch. Sexes alike. Juvenile undescribed. Voice. Male advertising song of three elements, first 1-4 sharp notes, then 3-4 more drawn-out notes, and emphatic final note, e.g. "chip, chip, dree-zee-zee, zéw", longer and more complex than song of *N. aurifrons*.
Habitat. Dense secondary growth, forest edge, stunted woody vegetation, often with abundant bamboos and ferns; avoiding forest interior. At c. 1150-1750 m.
Food and Feeding. Small fruits and insects, taken from foliage in short-range aerial sallies and by hover-gleaning.
Breeding. Not recorded. Male sings from thin horizontal perch.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Central Brazilian Hills and Tablelands EBA and Atlantic Forest Mountains EBA. Occurs in small numbers in Itatiaia National Park, in Rio de Janeiro-Minas Gerais. Much suitable habitat persists in protected areas within its rather limited range.
Bibliography. Develey (2004), Meyer de Schauensee (1982), Sick (1993, 1997), Stotz *et al.* (1996), Whitney *et al.* (1995).



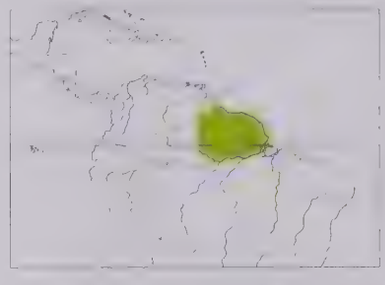
Genus *TYRANNEUTES* P. L. Sclater & Salvin, 1881

50. Dwarf Tyrant-manakin

Tyranneutes stolzmanni

French: Manakin nain **German**: Südliche Zwergpipra **Spanish**: Saltarín Enano

Taxonomy. *Pipra stolzmanni* Hellmayr, 1906, Marabitanas, Rio Negro, Brazil.
Systematic position of genus uncertain; probably closest to *Neopelma*, and both genera seem only distantly related to the typical piprids; probably closer to the Tyrannidae but traditionally included in present family, where retained pending further study. Forms a superspecies with *T. virescens*; ranges of the two approach one another closely, being separated by R Branco, lower R Negro and R Amazon. Monotypic.
Distribution. S Venezuela (Amazonas, W & S Bolívar) and Amazonia from E Colombia S (E from foothills of Andes) to Ecuador, Peru and N Bolivia, and E to NW & NC Brazil (E to R Negro and, S of Amazon, to Maranhão and S to S Mato Grosso).
Descriptive notes. 8-9 cm; 6·9-10 g. Tiny, drab manakin with very short tail, pale eyes. Plumage is uniformly olive above, throat to breast paler greyish-olive, belly pale yellow; iris yellowish-white or orange-tinged white to pale greyish or pale brown; bill dark, paler lower mandible; legs greyish. Differs from very similar *T. virescens* in lack of yellow crownstripe, pale eyes, marginally larger size with slightly longer tail. Sexes alike, female with marginally longer tail than male. Juvenile undescribed. Voice. Male advertising call an often repeated "jew-pit".



Habitat. Humid *terra firme* and, to lesser extent, *várzea* forest, especially on white sandy soils; rarely, forages out into edges and clearings. Mostly below 500 m; locally higher in W, to 1000 m in Ecuador.
Food and Feeding. Mainly small fruits; also invertebrates. Forages in lower and middle strata, but sometimes high into canopy.
Breeding. Single record: young in nest mid-Apr, E Ecuador. Nest a tiny cup (5 cm outside diameter, 3·5 cm inside, 3 cm deep) of sparse black rootlets, 1·5 m up in small sapling. Male display includes flying with very fast wingbeats from perch at top of very tall tree, straight up to height of 20-30 m, then "dive-bombing" back to same perch.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common in much of range; often numerous in suitable habitat, but very easily overlooked. Notably inconspicuous, frequently detected only by its calls.
Bibliography. Allen (1995), Bates & Parker (1998), Best *et al.* (1997), Blake (1962), Butler (1979), Dubs (1992), Foster (1996, 1997), Friedmann (1948), Greeney *et al.* (2004), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Munn (1985), Oren & Parker (1997), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1960, 1967, 1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Walther (2004), Willard *et al.* (1991), Zimmer, J.T. (1930), Zimmer, K.J. & Hilty (1997), Zimmer, K.J. *et al.* (1997).

51. Tiny Tyrant-manakin

Tyranneutes virescens

French: Manakin minuscule **German**: Nördliche Zwergpipra **Spanish**: Saltarín Diminuto

Taxonomy. *Pipra virescens* Pelzeln, 1868, Manaus, Brazil.
Systematic position of genus uncertain; probably closest to *Neopelma*, and both genera seem only distantly related to the typical piprids; probably closer to the Tyrannidae but traditionally included in present family, where retained pending further study. Forms a superspecies with *T. stolzmanni*; ranges of the two approach one another closely, being separated by R Branco, lower R Negro and R Amazon. Monotypic.
Distribution. E Venezuela (NE & SE Bolívar), the Guianas and NE Amazonian Brazil (from R Branco and lower R Negro E to Amapá).
Descriptive notes. 7-8 cm; 6·8·5 g. Tiny, drab manakin with very short tail, dark eyes. Male has yellow crown patch (largely concealed); rest of head and upperparts dull olive, throat to breast paler greyish-olive, belly pale yellow; iris dark, brownish; bill dark, paler lower mandible; legs greyish. Differs from very similar *T. stolzmanni* in having yellow on crown, dark eyes, slightly smaller size with even shorter tail. Female is very like male, but has less yellow on crown, slightly longer tail. Juvenile undescribed. Voice. Male advertising call "whippy-jebree", repeated at intervals of 3-6 seconds.

Habitat. Humid forest, mainly *terra firme*, including on sandy soils; to c. 500 m.
Food and Feeding. Mainly small fruits, but also some insects, including lepidopteran larvae. Forages in lower and middle strata. Techniques include at least occasional sally-gleaning and hover-gleaning.
Breeding. Not recorded. Male display includes slow floating flights with rapid wingbeats between low perches, also sideways peering while perched; also spectacular towering flight above canopy followed by dive back to perch.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common or common, but very easily overlooked. Occurs in Imataca Forest Reserve and El Dorado, in Venezuela; reasonably common in Raleigh Falls-Voltzberg National Park and Brownsberg Nature Park, in Surinam.
Bibliography. Cohn-Haft *et al.* (1997), Cracraft (1985), Forrester (1993), Gilliard (1941), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1929), Hilty (2003), Meyer de Schauensee (1982), Novaes (1978a), Ridgely & Tudor (1994), Sick (1993, 1997), Snow, D.W. (1961), Snyder (1966), Stotz *et al.* (1996), Thiollay (1992), Thiollay & Jullien (1998), Tostain *et al.* (1992), Walther (2004).

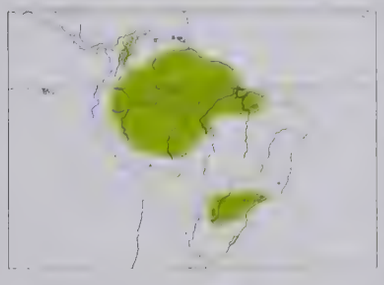
Genus *PIPRITES* Cabanis, 1847

52. Grey-headed Piprites

Piprites griseiceps

French: Piprite à tête grise **German**: Graustirnpiprites **Spanish**: Piprites Cabecigrís
Other common names: Grey-headed/Grey-hooded Manakin

Taxonomy. *Piprites griseiceps* Salvin, 1865, Tucurrique, Costa Rica.
Systematic position of genus uncertain; although traditionally included in present family, may be closer to Tyrannidae or Cotingidae. Forms a superspecies with *P. chloris*. Monotypic.
Distribution. Extreme E Guatemala and N Honduras S, mainly in Caribbean coastal areas, to extreme W Panama.
Descriptive notes. 12 cm; 16 g. Rather long-tailed for a manakin, and with tyrannid-like coloration and big-eyed, staring look. Has slate-grey head, conspicuous white eyering; olive-green upperparts, wing feathers with paler yellow-green margins; yellowish-olive below, paler and yellower on throat and belly; iris dark; bill blackish, paler lower mandible; legs grey. Sexes alike. Juvenile



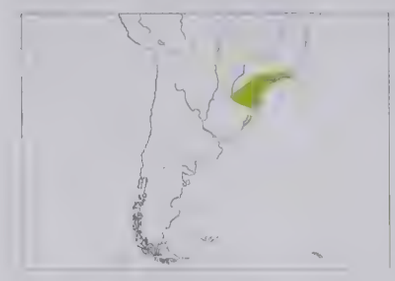
has olive-coloured head. Voice. Main calls a soft, liquid, rolling "purrr" and soft "chip" notes; song an elaborate, structured medley of staccato and rolling notes.
Habitat. Occupies forest and adjacent tall secondary growth; mostly at 100-600 m, locally up to 750 m.
Food and Feeding. Small fruits and insects, taken in flight sallies. Often joins mixed-species foraging flocks.
Breeding. Apparently unrecorded.
Movements. No information.
Status and Conservation. Not globally threatened. Restricted-range species: present in Central American Caribbean Slope EBA. Poorly known species. Uncommon to rare, and local; previously considered Near-threatened. Very few records in N & S parts of range; only one record from Guatemala. Occurs in Braulio Carrillo National Park and La Selva Biological Reserve, in Costa Rica.
Bibliography. Angehr (2003), Collar *et al.* (1994), Cooper (1997), Eisenmann (1955), Engleman (1996a), Hellmayr (1929), Howell & Webb (1995a), Kirwan & Hornbuckle (1997a), Land (1970), Lovey & Stiles (1994), Monroe (1968), Slud (1960, 1964), Stiles (1983, 1985), Stiles & Skutch (1989), Stotz *et al.* (1996).

53. **Wing-barred Piprites**

Piprites chloris

French: Piprite verdin **German**: Gelbzügelpiprites **Spanish**: Piprites Verde
Other common names: White-winged Piprites, Wing-barred Manakin

Taxonomy. *Pipra chloris* Temminck, 1822, Ipanema, São Paulo, Brazil.
Systematic position of genus uncertain; although traditionally included in present family, may be closer to Tyrannidae or Cotingidae. Forms a superspecies with *P. griseiceps*. Seven subspecies recognized.
Subspecies and Distribution.
P. c. perijana Phelps, Sr & Phelps, Jr, 1949 - subtropical zone of Sierra de Perijá on N Colombia-Venezuela border, and of E Andes in S Táchira (Venezuela).
P. c. antioquiae Chapman, 1924 - N Colombia at N end of C Andes and in middle Magdalena Valley.
P. c. chlorion (Cabanis, 1847) - N, E & S Venezuela (coastal mountains in Carabobo, Aragua and Sucre, also Amazonas and Bolívar), the Guianas, E Colombia and lower Amazonian Brazil (E Amazonas E to Amapá).
P. c. tschudii (Cabanis, 1874) - extreme E Colombia (SE Guainía), extreme S Venezuela (S Amazonas), W & C Amazonian Brazil, E Ecuador and C & E Peru (S to Junín).
P. c. boliviana Chapman, 1924 - SW Amazonian Brazil and N Bolivia.
P. c. grisescens Novaes, 1964 - E part of N Brazil (E Pará and Maranhão).
P. c. chloris (Temminck, 1822) - E Brazil (Espírito Santo, and from S Mato Grosso do Sul E to Rio de Janeiro, S to N Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).



Descriptive notes. 12·5-14 cm; 15-21 g. Distinctive, with yellow eyering and wingbars reminiscent of some Nearctic vireos (*Vireo*), but large round head manakin-like. Nominate race has golden forehead and lores, olive-green crown, a little grey on nape; upperparts olive-green, upperwing-coverts and tertials with large, conspicuous creamy to white terminal spots, flight-feathers and tail edged paler dull green; underparts yellow, clouded with olive on breast; iris dark; bill greyish; legs light pinkish-grey. Sexes alike. Juvenile undescribed. Races vary mainly in coloration and brightness: *tschudii* is brighter olive above, nape and neck side grey; *perijana* resembles previous, but tail broadly tipped yellowish-white; *antioquiae* has upperparts brighter green, nape with less grey, brighter and clearer yellow underparts less suffused with olive; *chlorion* has yellow throat, is light greyish below, belly whiter, undertail-coverts yellowish; *boliviana* is like last but breast and ventral region yellower, grey band across centre of abdomen; *grisescens* is greyer overall. Voice. Song a rhythmic, far-carrying sequence, e.g. "whip, pip-pip, pidipip, whip", variable but always with hesitant cadence.
Habitat. Humid forest and mature secondary woodland, including *Araucaria* forest in S, and locally cloudforest in N. Favours areas with dense understorey or high vine tangles in trees. Mostly below 1000 m, locally to 1700 m; to 2000 m in N Venezuela.
Food and Feeding. Apparently mainly insects; small fruits occasionally taken. Insects gleaned from foliage, also hover-gleaned in short aerial sally. Regularly forages in forest canopy, accompanying mixed-species flocks.
Breeding. Male in breeding condition in May in Colombia (Antioquia); peak of singing in May-Jun in N Venezuela. Only one nest known to date, remarkable among manakins in being in a cavity, with no suspended nest structure. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common in much of range; often seems to be rather local, as for example in Ecuador and Colombia. Population of isolated nominate race in SE of range undoubtedly much reduced by extensive destruction of lowland forest; occurs, however, in several protected areas, including Augusto Ruschi Biological Reserve and Iguaçu National Park, in Brazil, Iguazú National Park, in Argentina, and Ybicuí National Park, in Paraguay.
Bibliography. Allen (1995), Bangs & Penard (1918), Bates & Parker (1998), Best *et al.* (1997), Blake (1962), Bond *et al.* (1989), Brooks *et al.* (1993), Butler (1979), Canevari *et al.* (1991), Capper *et al.* (2000), Chebez *et al.* (1999), Cohn-Haft *et al.* (1997), Dubs (1992), Fraga & Narosky (1985), Friedmann (1948), Gilliard (1941), Haffer (1967), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Lowen *et al.* (1996), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1982), Munn (1985), Narosky & Yzurieta (1993), Navas & Bó (1988), Oren & Parker (1997), de la Peña (1989), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), do Rosário (1996), Sick (1993, 1997), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Tobias *et al.* (1993), Tostain *et al.* (1992), Willard *et al.* (1991), Zimmer & Hilty (1997), Zimmer *et al.* (1997).

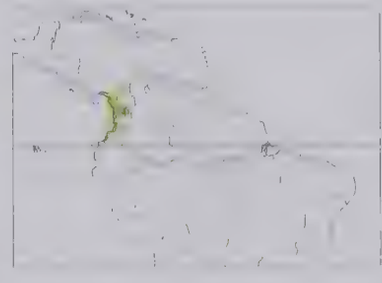
54. **Black-capped Piprites**

Piprites pileata

French: Piprite chaperonné **German**: Zimtpiprites **Spanish**: Piprites Capirotado
Other common names: Black-capped Manakin

Taxonomy. *Pipra pileata* Temminck, 1822, Curitiba, Paraná, Brazil.
Systematic position of genus uncertain; although traditionally included in present family, may be closer to Tyrannidae or Cotingidae. Monotypic.
Distribution. SE Brazil (S Minas Gerais and Rio de Janeiro S to N Rio Grande do Sul) and extreme NE Argentina (Misiones).

Descriptive notes. 12·12·5 cm; 1 male 15 g. Highly distinctive, with conspicuous whitish on primaries. Male has black crown to nape, contrasting chestnut upperparts; remiges blackish, edged yellowish-green, prominent whitish at base of primaries; tail rufous, mostly black central feathers; lower forehead and face down to breast cinnamon-rufous, becoming paler and yellower on lower underparts; iris dark; bill yellow; legs orange-yellow. Female resembles male but much duller above, back dull olive, upperwing-coverts dusky with pale greyish tips (faint greyish wingbars). Juvenile undescribed. Voice. Calls include single "whééu", sometimes followed by a series of briefer, less loud notes; song a fast, rollicking sequence, e.g. "chik, chik, cheeút, chee-unh", variable but always with chortling quality.
Habitat. Montane Atlantic Forest, in S parts of range often associated with *Araucaria*; 900-2000 m.
Food and Feeding. Mainly small fruits, with those of the genera *Geonoma* (Arecaceae), *Rapanea* (Myrsinaceae) and *Leandra* (Melastomataceae) recorded as eaten; also small arthropods. Fruits plucked from branches; arthropods taken from foliage by gleaning or hover-gleaning. Forages mostly in canopy and subcanopy, but observed also in dense understorey of *Chusquea* bamboo thicket. Often accompanies mixed-species foraging flocks.
Breeding. Male specimen with greatly enlarged testes in late Sept, and display observed in Sept. No other information.
Movements. Apparently resident; some possible altitudinal movements suspected, e.g. in Itatiaia region of Brazil.
Status and Conservation. VULNERABLE. Restricted-range species: present in Atlantic Forest Mountains EBA. Rare and local, with very sparse distribution; seems never to have been numerous, and habitat loss has probably reduced its numbers even further. Almost all recent records are from Itatiaia National Park, on Rio de Janeiro-Minas Gerais border; on Itatiaia massif occurs in dense upper montane forest, which has suffered far less than adjoining areas of lowland forest, and in this and other protected montane areas in N of range, including Serra da Bocaína National Park and Campos do Jordão State Park, its survival prospects should be good. Very few records, recent or old, from S part of range, where *Araucaria* forest now extensively destroyed; may still occur in Aparados da Serra National Park, in Rio Grande do Sul. Outside Brazil, recorded once in extreme NE Argentina, in Sept 1959; alleged occurrence in Iguazú National Park not proven. Field surveys required in order to establish whether the species is still present at historical localities in e.g. Paraná, and to determine its exact habitat requirements; in addition, important to clarify extent, if any, of seasonal movement to lower elevations, as lower-altitude forest in the region is at greater risk of destruction.
Bibliography. dos Anjos & Schuchman (1997), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Collar & Andrew (1988), Collar *et al.* (1992), Cracraft (1985), Forrester (1993), Hellmayr (1929), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1982), Narosky & Yzurieta (1993), de la Peña (1989), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stotz *et al.* (1996), Tobias *et al.* (1993).



Genus *SAPAYOA*, Hartert, 1903

55. **Broad-billed Sapayoa**

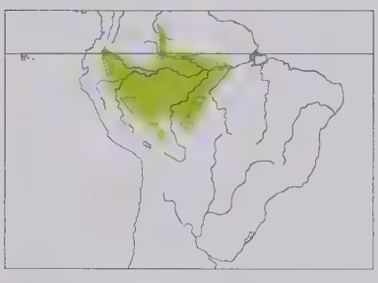
Sapayoa aenigma

French: Sapayoa à bec large **German**: Breitschnabelpipra **Spanish**: Sapayoa
Other common names: Sapayoa, Broad-billed Manakin

Taxonomy. *Sapayoa aenigma* Hartert, 1903, River Sapayo [= Zapallo Grande], Esmeraldas, Ecuador.
Systematic position and affinities enigmatic. Seems to be close to the Tyrannidae, and has sometimes been placed in its own separate family, Sapayoaidae. Traditionally included in present family, although nest (only recently discovered) and social organization unlike those of typical piprids; this treatment retained, pending further study. Monotypic.
Distribution. Panama (E from Canal Zone) and W Colombia (Pacific coast and E to middle Magdalena Valley) S to extreme NW Ecuador (Esmeraldas, NW Pichincha).

Descriptive notes. 13·5-15 cm; 20·8 g. Dull, tyrannid-like species with broad, flat bill, rictal bristles; tail long for a manakin. Male has yellow crownstripe (usually concealed); rest of plumage mostly plain olive, wings and tail duskier, throat and belly tinged yellower; iris dull reddish-brown; bill black; legs grey. Female lacks yellow crownstripe. Juvenile undescribed, presumably resembles female. Voice. Inadequately known; two calls described as a soft, somewhat nasal trill, and slightly louder "chip, ch-ch-ch".
Habitat. Humid forest, in lower and middle strata, often near streams and ravines; to 1100 m.

Food and Feeding. Small fruits and insects. Perches, often for considerable periods, peering around, before making aerial sallies; takes insects from air as well as from foliage, unlike typical manakins. Regularly accompanies mixed-species foraging flocks.
Breeding. Egg-laying in late Apr or early May, and a nest with chicks in May, in Panama; birds in breeding condition in Feb-Apr in W Colombia. One nest found, pear-shaped, tapered at top and rounded at bottom, composed of long strips of fibrous outer bark, with 30 cm of loose fibrous strands hanging below, entrance at side near bottom, covered by hood of fibres, suspended from lower branch of *Perebea* tree 2 m above forest stream; contained 2 nestlings, fed by both parents.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Status not well known, largely because species is generally quiet and unobtrusive. Apparently rare to uncommon, and possibly rather local in distribution.
Bibliography. Best *et al.* (1997), Butler (1979), Chapman (1917c), Christian (2001), Cracraft (1985), Delgado (1985), Eisenmann (1955), Fjeldså *et al.* (2003), Haffer (1975), Hellmayr (1929), Hilty & Brown (1986), Lanyon, W.E. (1985), Mena & Jahn (2002), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Stotz *et al.* (1996), Wetmore (1972).



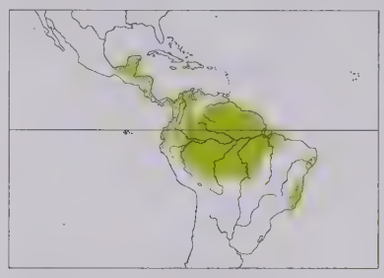
Genus *SCHIFFORNIS* Bonaparte, 1854

56. Varzea Mourner

Schiffornis major

French: Antriade roussâtre **German**: Zimttrauerkotinga **Spanish**: Llorón de Varzea
Other common names: Greater Manakin, Greater/Rufous Schiffornis

Taxonomy. *Schiffornis major* Des Murs, 1856, Sarayacu, Peru.
Systematic position of genus uncertain. Analysis of 19 characters, mostly anatomical, suggested that it is a member of a monophyletic assemblage of six superficially very diverse genera currently divided among Cotingidae, Tyrannidae and the present family; also, recent analyses of genetic data resulted in its grouping with the genera *Pachyramphus* and *Tityra* (both at present provisionally placed in Tyrannidae) in a "tityrine clade"; traditional placement in present family almost certainly inappropriate, but retained pending further study. Two subspecies recognized.
Subspecies and Distribution.
S. m. duidae J. T. Zimmer, 1936 - S Venezuela (W Amazonas).
S. m. major Des Murs, 1856 - S Colombia, E Ecuador and W & C Amazonian Brazil (E to mouth of R Tapajós) S to E Peru and N Bolivia.



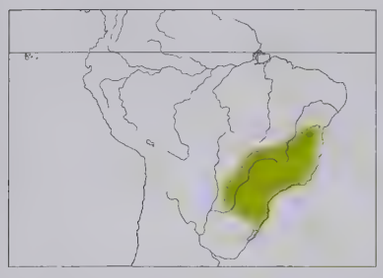
Descriptive notes. 15-15·5 cm; 31 g. Nominate race has grey area around eye, extent variable, sometimes reaching crown, occasionally lacking; head otherwise rufous, lores paler, back rufous, rump and tail bright cinnamon-rufous, wings dusky with broad rufous edgings; throat greyish-buff, underparts cinnamon-rufous, becoming paler cinnamon-buff on belly and vent; iris dark brownish; bill and legs dark grey to blackish. Sexes alike. Juvenile undescribed, apparently resembles adult. Race *duidae* differs from nominate in having head almost entirely grey, back duller brown. Voice. Song a leisurely series of loud slurred whistled notes, with pauses of 2-3 seconds towards end; "chrrrrrrt" rattle in excitement.
Habitat. Seasonally flooded forest (*várzea*), to 300 m.
Food and Feeding. Not well known; apparently similar to that of *S. turdina*.
Breeding. No information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common, but local throughout range. Poorly known species, heard much more often than seen.
Bibliography. Allen (1995), Bates & Parker (1998), Butler (1979), Friedmann (1948), Hellmayr (1929), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson (1997), Robinson & Terborgh (1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Traylor (1958), Willard *et al.* (1991), Zimmer & Hilty (1997).

57. Thrush-like Mourner

Schiffornis turdina

French: Antriade turdoïde **German**: Brauntrauerkotinga **Spanish**: Llorón Turdino
Other common names: Thrush-like Manakin/Schiffornis; Brown Mourner/Manakin/Schiffornis (*veraepacis*)

Taxonomy. *Muscicapa turdina* Wied, 1831, Bahia, Brazil.
Systematic position of genus uncertain. Analysis of 19 characters, mostly anatomical, suggested that it is a member of a monophyletic assemblage of six superficially very diverse genera currently divided among Cotingidae, Tyrannidae and the present family; also, recent analyses of genetic data resulted in its grouping with the genera *Pachyramphus* and *Tityra* (both at present provisionally placed in Tyrannidae) in a "tityrine clade"; traditional placement in present family almost certainly inappropriate, but retained pending further study. Present species forms a superspecies with *S. virescens*. Geographical variation involves both plumage and voice; pale and dark forms, as well as upland and lowland ones, occur, and situation especially complex in NW South America and adjacent Panama; possible taxonomic significance of vocal differences not understood; races probably constitute more than one species, but critical studies not yet undertaken. Thirteen subspecies recognized.
Subspecies and Distribution.
S. t. veraepacis (P. L. Sclater & Salvin, 1860) - Caribbean slope from SE Mexico S to Nicaragua, and both slopes in Costa Rica.
S. t. dumicola (Bangs, 1903) - W & C Panama.
S. t. panamensis Hellmayr, 1929 - lowlands of C & E Panama and NW Colombia (N Chocó, W Córdoba).
S. t. acrolophites Wetmore, 1972 - extreme E Panama (Cerro Tacarcuna) and adjacent highland areas of NW Colombia.
S. t. rosenbergi (Hartert, 1898) - Pacific slope from W Colombia S to extreme NW Peru (Tumbes).
S. t. stenorhyncha (P. L. Sclater & Salvin, 1869) - N & NE Colombia and N Venezuela (Zulia E to Aragua).
S. t. olivacea (Ridgway, 1906) - SE Venezuela and Guyana.
S. t. aenea J. T. Zimmer, 1936 - E slope of E Andes in Ecuador and adjacent N Peru.
S. t. amazona (P. L. Sclater, 1861) - lowlands from extreme E Colombia and S Venezuela S to E Ecuador, E Peru and NW & W Brazil (E to R Negro and NW Mato Grosso).
S. t. wallacii (P. L. Sclater & Salvin, 1867) - Surinam, French Guiana and E Amazonian Brazil (lower R Negro E to Amapá and, S of Amazon, from R Tapajós and lower R Teles Pires E to Maranhão).
S. t. steinbachi Todd, 1928 - SE Peru and N Bolivia.
S. t. intermedia Pinto, 1954 - E Brazil (Paraíba, Pernambuco, Alagoas).
S. t. turdina (Wied, 1831) - SE Brazil (S Bahia S to Espírito Santo).



Descriptive notes. 15·5-16·5 cm; average 35 g in Costa Rica (*veraepacis*), 31 g in French Guiana and N Brazil (Belém) and 28-34 g in Surinam (*wallacii*), and 27·2-31·5 g in C Brazil (Mato Grosso, *amazona*). Rather uniform and dull-coloured, with prominent dark eye set off by indistinct pale eyering. Nominate race is dull brownish-olive above, wings edged rufescent, slightly paler olive-grey below, breast browner; iris brown to dark brown; bill blackish; legs olive-greyish. Sexes alike. Juvenile resembles adult. Races vary mainly in plumage tone, to lesser extent also in size, largest in NW & SE extremes of range: *veraepacis* is dark brownish-olive, wings warmer brown, belly duller and greyer, largest; *panamensis* is lighter, with brighter brown crown, wings and tail, cinnamon-rufous throat contrasting with greyish-olive breast and belly; *dumicola* is darker and more olive-brown than previous, more uniform both above and below; *acrolophites* is very like last, but darker and more olive overall, with chin and throat chestnut-brown; *rosenbergi* is dark brownish-olive below, with no hint of grey; *olivacea* is very dull and uniform-looking, olive-brown; *aenea* differs from previous two in having crown more rufescent, upperparts browner (less greenish), wings warmer brown, breast more brownish, belly somewhat brighter and more greenish-tinged; *amazona* has rufescent-tinged crown like last but is paler overall, less brown and more olive above, with moderately developed tawny colour on throat, more greyish below, dull belly; *wallacii* resembles previous but is paler throughout, pale belly; *stenorhyncha* is darker and more rufous-brown above than last, especially on wings, with yellowish-tinged brown throat and chest, somewhat contrasting greyish-olive lower underparts; *steinbachi* and *intermedia* are similar to nominate but smaller. Voice. Song, usually given at long intervals, a sequence of normally 2-4 clear, rich musical whistles, last one sharply upslurred, very variable geographically, e.g. in Mexico (*veraepacis*) "djeeeeu whee-chee" or sometimes 2-note "dweeeer weet", in Panama (*panamensis*) "teeuu, wheet-wheet, wheet", in Surinam (*wallacii*) "teeeeu, wheeeu-wheé-tu", on W slope in Ecuador (*rosenbergi*) very slow "teeeeu, weee-ti" but on E slope (*aenea*) much faster "teeeu wheeu-wheé-tu-tu" and in E lowlands (*amazona*) again a slower "teeeeu, weee, tu-weeeé", and in SE Brazil (nominate) somewhat sluggish "teeuu, yoowée, tu, tu-wee". Short rattling chatter also given.
Habitat. Humid forest, very infrequently adjacent tall second growth; almost always in interior, rarely near edge. Lowlands to c. 1500 m; locally to 1700 m in Costa Rica and Ecuador, occasionally to 1800 m in Venezuela N of R Orinoco. In SE Brazil (nominate race), occurs at lower altitudes than *S. virescens* where ranges overlap.
Food and Feeding. Fruits and insects. Takes larger fruits than do typical manakins; in French Guiana, capsules of Myristicaceae, Burseraceae and Meliaceae and berries of Annonaceae, Lauraceae and Moraceae eaten. More insectivorous than typical manakins. Forages solitarily, rarely joins mixed-species flocks. Works through forest undergrowth, often clings 1-2 m up on side of vertical stems while peering around; snatches insects from vegetation in short aerial sallies.
Breeding. Egg-laying in Feb-Aug (chiefly May) in Costa Rica, and in Feb (single record) in N Brazil; young being fed in Dec in French Guiana; birds in breeding condition in Jan-Jun in N Colombia. Nest a bulky cup mainly of large dead leaves or leaf skeletons, lined with rootlets or black fungal rhizomorphs, 0·6-1·8 m above ground in spiny palm, hollowed top of palm stump, vine tangle, or on small epiphyte, supported from below. Clutch 2 eggs; incubation period 20-21 days; fledging period not documented.
Movements. Almost certainly sedentary.
Status and Conservation. Not globally threatened. Generally uncommon to fairly common, but unobtrusive; heard far more often than seen. Fairly common to common in Mexico; locally fairly common in many parts of its extensive range, as e.g. in Costa Rica and Panama, and in Venezuela, Colombia and Ecuador; in general less numerous in lowland areas, e.g. uncommon to rare in lowlands of Costa Rica. Possibly extinct in deforested parts of Pacific slope of Panama, and E Brazilian populations (*intermedia*, nominate) in Atlantic coastal areas undoubtedly much reduced by deforestation. In radio-tracking studies in French Guiana, home ranges in breeding season of two males were 14·3 ha and 16·5 ha, respectively, and of one female 20·1 ha, all larger than those of typical manakins.

58. Greenish Mourner

Schiffornis virescens

French: Antriade verdâtre **German**: Olivtrauerkotinga **Spanish**: Llorón Verdoso
Other common names: Greenish Manakin/Schiffornis

Taxonomy. *Ptil[ochloris] virescens* Lafresnaye, 1838, Rio de Janeiro, Brazil.

Systematic position of genus uncertain. Analysis of 19 characters, mostly anatomical, suggested that it is a member of a monophyletic assemblage of six superficially very diverse genera currently divided among Cotingidae, Tyrannidae and the present family; also, recent analyses of genetic data resulted in its grouping with the genera *Pachyramphus* and *Tityra* (both at present provisionally placed in Tyrannidae) in a "tityrine clade"; traditional placement in present family almost certainly inappropriate, but retained pending further study. Present species forms a superspecies with *S. turdina*. Monotypic.

Distribution. SE Brazil (from S Goiás E to S Bahia, S to E Mato Grosso do Sul and N Rio Grande do Sul), E Paraguay and NE Argentina (Misiones, NE Corrientes).

Descriptive notes. 15·5 cm; male 21·5-24 g, female 26·7-28·5 g. Dull-looking, with indistinct pale eyering. Plumage is dull greenish-brown, wings and tail contrastingly rufescent; paler below; iris dark brown; bill and legs olive-greyish. Distinguished from similar *S. turdina* by greener general coloration, contrastingly rufescent wings and tail, slightly smaller bill. Sexes alike. Juvenile not described. Voice. Song, usually given at long intervals, a sequence of 2-4 clear musical whistles, with emphasis on final notes.

Habitat. Humid forest, gallery forest and mature secondary woodland; to c. 1200 m. Occurs at higher elevations than *S. turdina* where ranges overlap.

Food and Feeding. Little information; adult insects and caterpillars recorded as eaten. Apparently similar to *S. turdina*.

Breeding. Single record: nest found in Brasília, 19th Dec, a large cup of leaves placed 3 m above ground in upright fork of bush, contained 2 eggs. No other information.

Movements. None recorded.

Status and Conservation. Not globally threatened. Rather common in some adequately protected areas of very humid, low montane forest. Not well known; heard much more frequently than it is seen.

Class AVES

Order PASSERIFORMES

Suborder TYRANNI

Family TYRANNIDAE (TYRANT-FLYCATCHERS)

- Tiny to medium-sized passerines, with plumage mostly various combinations of black, brown, white, yellow and green, some duller, a few much brighter; very diverse in body proportions, bill shape and structure, and leg length.
- 6·5 -28 cm.

- America.
- Wide variety of habitats, mostly forest and woodland of various types, also grassland.
- 104 genera, 429 species, 1081 taxa.
- 24 species threatened; none extinct since 1600.

Systematics

The tyrant-flycatchers, also referred to sometimes as the New World flycatchers, constitute by far the largest family of birds in the Western Hemisphere, and also one of the most diverse. With its species-richness peaking in the Neotropics, Tyrannidae encompasses ecological and morphological equivalents of a huge array of bird groups found elsewhere in the world. The tyrannid radiation includes lineages that exhibit evolutionary convergence with typical Old World flycatchers (Muscicapidae) and monarch-flycatchers (Monarchidae), the New World warblers (Parulidae) and Old World warblers (Sylviidae), the true shrikes (Laniidae), the babblers (Timaliidae), the jays (Garrulinae), the wrens (Troglodytidae), the gnatcatchers (Polioptilidae), the pipits (Motacillidae), the thrushes (Turdidae), the flowerpeckers (Dicaeidae), and a coraciiform family, the todies (Todidae). Tyrant-flycatchers include elegant species that execute aerial sallies from perches high atop the tallest tropical trees; massive, hook-billed predators that pounce on lizards in the montane scrub; long-legged terrestrial runners of the arid South American coast and the barren Andean Altiplano; delicate, nervously active insectivores that move through tropical forest canopies with mixed-species flocks; and minute, spatulate-billed sprites that leap upwards to snatch insects from the undersides of leaves in dense scrub and streamside thickets. They vary in body size from the world's smallest passerine bird to robust, shrike-sized predators.

Currently, Tyrannidae comprises a total of 429 species, placed in 104 genera. The bulk of the family's members almost certainly form a monophyletic group, united by several internal anatomical features and by shared DNA characters. An additional assemblage of 23 species consists of the mourners (*Laniocera*), the tityras (*Tityra*), the becards (*Pachyramphus*) and the monotypic genus *Xenopsaris*, all of which are taxonomically problematic genera that have for more than a hundred years been shifted back and forth between the cotingas (Cotingidae) and the Tyrannidae. They display genetic, anatomical and behavioural characters that could unite them with either family, and other characters that seem to place them as sister-taxa to both. Even now, although many authors treat them as members of the Tyrannidae, others place some or all of the four genera within the Cotingidae. The problematic taxonomic status of these groups presumably reflects an early divergence from the primitive, proto-tyrannid ancestor.

Considerable anatomical and molecular evidence indicates that Tyrannidae falls within a natural, monophyletic group of suboscine families that also includes the manakins (Pipridae) and the cotingas. This group is commonly regarded as constituting the superfamily Tyrannoidea, or alternatively, as in the present work, the suborder Tyranni. Although still imperfect, evidence is mounting that Tyrannidae itself is monophyletic. All tyrant-flycatchers, including the genera *Tityra*, *Pachyramphus* and *Xenopsaris*, possess a pair of small, variously shaped cartilaginous plates located within the internal tympaniform membranes inside the syrinx. The function of this internal cartilage is entirely unknown, but this peculiar trait is almost restricted to the Tyrannidae and thus comes as close to being a definitive character for the family as does any other. Within the suborder Tyranni, a few other genera presently

For years, eminent taxonomists were mystified by an odd Zimmerius *tyrannulet lying in a drawer at Chicago's Field Museum. The puzzle of its identity was finally solved when identical birds were discovered in white-sand forests near Iquitos, Peru. The* ***Mishana Tyrannulet*** *had escaped detection until 2001 because it was confined to a specialized habitat in a small range. Moreover, tyrannulets are not the most prepossessing of birds, and are easily overlooked. A large proportion of all new species described over the last two decades have been tyrannids; several others await formal description, and more are sure to follow.*

[*Zimmerius villarejoi*, Alto Nanay, Loreto, Peru. Photo: José Álvarez Alonso]

Subdivision of the Tyrannidae.

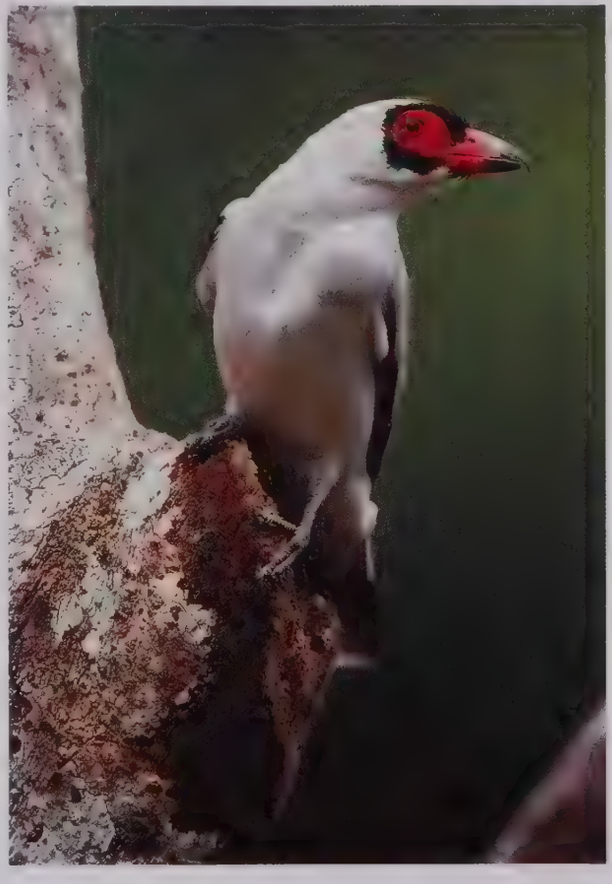
[Figure: Norman Arlott, Hilary Burn, Ian Lewington and Ian Willis]

treated as non-tyrannids do also have internal syringeal cartilages. These are *Oxyruncus* and *Iodopleura*, placed in the Cotingidae, and the five genera *Schiffornis*, *Piprites*, *Sapayoa*, *Tyranneutes* and *Neopelma*, currently treated as belonging to Pipridae. In many other respects as well, these seven genera present some confusion with regard to their taxonomic affinities, and it seems likely that they represent primitive offshoots from the early tyrannoid ancestor. R. O. Prum and W. E. Lanyon, the two specialists in tyrannoid syringeal morphology, have suggested that the presence of internal cartilage is not universally homologous but was, instead, independently derived in several groups, presumably early in the evolutionary radiation of the Tyranni. Of these groups, only the Tyrannidae then underwent the spectacularly successful radiation that gave rise to the huge family that we see today.

Another syringeal character, the presence of an intrinsic M. obliquus ventralis muscle, also comes very close to being a definitive feature of the Tyrannidae. It appears, however, to be missing in several genera otherwise considered to belong in the family: *Terenotriccus*, *Myiobius*, *Pyrrhomyias*, *Onychorhynchus*, *Tolmomyias*, *Todirostrum* and *Zimmerius*. This muscle is absent also in the taxonomically controversial *Tityra* and *Pachyramphus*.

Robust evidence from DNA studies affirms the unity of the Tyranni as a natural group, but these studies, too, remain equivocal about the strict monophyly of the Tyrannidae within this group. DNA-DNA hybridization evidence was interpreted as revealing such a deep split within the "true" tyrant-flycatchers that it was deemed necessary to erect a new subfamily, Pipromorphinae, later changed to Mionectinae, in order to recognize a previously unsuspected assemblage that included the genera *Mionectes* and *Todirostrum* and relatives. Moreover, the DNA-hybridization distance between these two otherwise "typical" tyrant-flycatcher groups was greater than that separating the bulk of the tyrannids from the manakins and cotingids. Consequently, C. G. Sibley and J. E. Ahlquist, in their major taxonomic compendium, treated the latter two groups as subfamilies Piprinae and Cotinginae, respectively, within a greatly enlarged family Tyrannidae. A number of

A supposed Rufous-crowned Tody-tyrant (Poecilotriccus ruficeps) *collected south of the River Marañón in 1970 differed from its sister-species to the north in lacking black markings on the face and neck. Despite this discovery it took several decades before sufficient material was gathered for the species to be formally named in 2001.* ***Johnson's Tody-tyrant*** *was found to differ from its northern counterpart, not only in terms of morphology, but in the pattern of its song. It is restricted to the Cordillera de Colán and neighbouring ranges, and joins a relatively long list of tyrannids newly described to science in the last few years.*



[*Poecilotriccus luluae*, Abra Patricia, San Martín, Peru. Photo: Jon Hornbuckle]

more recent studies, based on DNA-sequence data, refute this hypothesis, however, and these, together with a considerable body of anatomical, morphological and behavioural evidence, strongly support true monophyly of the Tyrannidae. Nevertheless, it should be noted that DNA-sequence data do suggest that *Tityra* and *Pachyramphus* represent a sister-group to the true tyrant-flycatchers, and that this group perhaps also contains the enigmatic genus *Schiffornis*.

Generic limits, and even many suprageneric assemblages, of tyrant-flycatchers are reasonably clear and well defined by modern phylogenetic analyses. In contrast, major taxonomic divisions at the level of the subfamily remain rather informally designated, and present fuzzy boundaries, as the subfamilial affinities of a number of genera are in doubt. Thus, despite over a century of published research and debate, and a host of recent studies that have clarified many of the major groupings in the family, it is not yet possible to provide entirely exception-free technical diagnoses that subdivide the Tyrannidae definitively into subfamilies. The most recent comprehensive revision of the Tyrannidae, completed by M. A. Traylor in 1977 and published two years later in his compilation for Volume 8 of J. L. Peters's *Checklist of the Birds of the World*, recognized three typical subfamilies, with a fourth more loosely attached. This arrangement has been generally followed by most subsequent authors, although a number of genera have been moved within their respective subfamilies, or shifted from one subfamily to another, on the basis of more recently published, large-scale comparative analyses and a steady production of studies clarifying the affinities of individual genera.

It is worth noting here that, when dealing with such a large and complex family as Tyrannidae, the assessment of relationships among genera and species is facilitated by investigation of a number of very different factors. While anatomical, morphological and genetic characteristics are obviously of great importance, such additional aspects as voice and behaviour are often considered significant in indicating possible affinities. Details of nest architecture and placement, and foraging behaviour and diet, as well as details of vocalizations, frequently provide clues as to relationships in cases where few other data are available. In the following paragraphs in this section, therefore, these aspects are covered in some detail.

Traylor divided the Tyrannidae into three main groups, with the genera *Tityra* and *Pachyramphus* forming a fourth, explicitly more distant, subfamily, and *Xenopsaris* isolated as being of uncertain position (*incertae sedis*). For the three typical groups he preserved the subfamily names Elaeniinae, Fluvicolinae and Tyranninae that had been used by early taxonomists such as A. H. Garrod, P. L. Sclater, H. von Berlepsch, R. Ridgway, H. von Ihering and C. E. Hellmayr. The last two authors, especially, relied extensively on variations in nest form as a means of recognizing subfamilial divisions within the family. Traylor did the

The genus Tityra *contains a trio of distinctive species, the commonest of which is the* ***Masked Tityra****. With their white plumage, sluggish behaviour, unusual internal anatomy, and weird guttural croaking calls, tityras are not closely related to the rest of the tyrant-flycatcher assemblage. Along with* Pachyramphus *and* Xenopsaris*, they are placed in the subfamily Tityrinae, a category best viewed as a sister-group to the true tyrant-flycatchers. Future research may disband the Tityrinae, and redistribute its constituent genera amongst other problematic tyrannoid families, but at the moment such a revision is premature.*

[*Tityra semifasciata costaricensis*, La Selva Biological Reserve, Costa Rica. Photo: Marco Saborío]

*The **Greyish Mourner** has been transferred back and forth between the Tyrannidae and Cotingidae for well over a century. Although it has some characteristics of both families, anatomical and behavioural evidence now clearly prove that this species is a true tyrant-flycatcher, related to the large genus* Myiarchus *and its other hole-nesting relatives, including the genera* Casiornis *and* Sirystes. *The very similar mourners of the genus* Laniocera, *however, remain of uncertain relationship outside the true tyrant-flycatchers, and, along with the genera* Schiffornis, Laniisoma *and* Iodopleura, *they probably represent a very primitive divergence from proto-tyrannid ancestors.*

[*Rhytipterna simplex simplex*, Murici Ecological Reserve, Alagoas, Brazil. Photo: Dante Buzzetti]

same, although he also included information from important morphological studies of cranial and syringeal characteristics carried out by, respectively, S. L. Warter and P. Ames. After the appearance of Traylor's classification, a series of exhaustive comparative studies of cranial and syringeal anatomy was published by W. E. Lanyon. The subsequent work of S. M. Lanyon and Prum, focused largely on suboscine groups peripheral to the tyrant-flycatchers, made significant contributions to the current classification of the Tyrannidae. In addition, M. McKittrick undertook a comprehensive analysis of monophyly in the group, and numerous investigators have carried out studies of key tyrannid subgroups based on protein allozymes, DNA sequences, morphology, and behaviour. The massive DNA-DNA hybridization study by Sibley and Ahlquist corroborated many previously proposed relationships, but also suggested certain controversial ones not supported by robust anatomical or biochemical evidence. Until further investigation has been carried out, it is considered better to treat the classification of Sibley and Ahlquist, and specifically the recognition of the subfamily Mionectinae, with a degree of caution.

*After a sequence of incarnations, the unassuming "cinnamon manakin", "tyrant-manakin" or simply "neopipo", has been re-invented as the **Cinnamon Tyrant**. This unsettled nomenclature stems from the difficulty of assigning this species to Pipridae or Tyrannidae. Traditionally placed in the former, it is now installed in the latter. It appears to be most closely allied to the Ruddy-tailed Flycatcher* (Terenotriccus erythrurus), *a common and widespread species whose similarity to the "neopipo" was long noted by ornithologists. The Cinnamon Tyrant is partial to stunted forests on sandy soils, where it outnumbers the Ruddy-tailed Flycatcher.*

[*Neopipo cinnamomea cinnamomea*, Alto Tigre, Loreto, Peru. Photo: José Álvarez Alonso]

The three "typical" subfamilies are, on the whole, quite different from one another. Elaeniinae is largely tropical in terms of latitude and elevation, and contains almost half of the tyrant-flycatcher species. Its members are small to medium-sized tyrannids, a large proportion of them being nondescript green birds with a rounded or needle-like small bill, and they forage in densely vegetated habitats. The Northern Beardless Tyrannulet (*Camptostoma imberbe*) is the only elaeniine to extend north of the Mexico-USA border, and even there it occupies only "Mexican" habitats, comprising Chihuahan desert, and cottonwood (*Populus*) riparian zones of Arizona, New Mexico and south Texas. At the southern extreme, a few species of *Elaenia* breed southwards into temperate-zone lowland habitats, and the montane genera *Mecocerculus* and *Anairetes* include several species that reach Argentina, central Chile and even the Juan Fernández Islands. Fluvicolinae is a widespread assemblage of medium-sized to large species possessing a rather large, broad bill, and occupying mainly woodland, montane and temperate forests, and open non-forest habitats such as alpine grassland. This subfamily contains the major radiation of tyrant-flycatchers that forage terrestrially, as typified by the ground-tyrants in the genus *Muscisaxicola*. The third subfamily, Tyranninae, contains the largest-bodied and largest-billed members of the family, and is found mainly in forest canopy and open woodland, forest borders and shrublands from Alaska south to Argentina. This group includes not only the noisy and conspicuous tyrannids of tropical towns, farms and roadsides, such as the kingbirds in the genus *Tyrannus*, but also a huge lineage of more retiring, woodland species that nest in tree cavities, such as the *Myiarchus* flycatchers and related genera.

The three remaining genera, *Tityra*, *Xenopsaris* and *Pachyramphus*, are placed together in a fourth subfamily, Tityrinae. Their relationships are rather obscure, and this arrangement perhaps remains one of convenience rather than an indication of any real affiliation. Indeed, Traylor included this group in Tyrannidae with evident misgivings, remarking that the "Tityrinae are tentatively allied to the Tyrannidae only because their crania more nearly resemble those of the tyrannids than those of the cotingids".

Although rich in species, Elaeniinae contains only a few basic types in terms of morphological and behavioural characteristics. Many of these genera conform to the "little green flycatcher" stereotype for which the family Tyrannidae as a whole is so famous. The basic plumage pattern is olive above and pale to rich yellowish below, with some olive tinge on the breast, indistinct facial markings, double wingbars, and occasionally a concealed crown patch. Indeed, this subfamily contains such a bewildering array of look-alikes that positive species identification in the field often is best accomplished by voice, and even then only after eliminating many species on the grounds of geographical impossibility. With the exception of a few of the *Poecilotriccus* tody-tyrants, sexes are alike in the Elaeniinae. The two antpipits in the genus *Corythopis* are exclusively terrestrial, although the members of several other genera, such as *Pseudotriccus*, spend their lives in dense vegetation within a few centimetres of the ground. The bill varies from small, slender and warbler-like to broad, flattened and spatulate in shape. Most elaeniine species forage by sally-gleaning, making short flights to glean insect prey within dense vegetation, and a large proportion of these species also regularly eat fruit. One genus, *Mionectes*, contains obligate frugivores that have developed a lek mating system more typical of the frugivorous manakins (see Breeding).

The subfamily Elaeniinae includes W. E. Lanyon's "*Elaenia* assemblage", hypothesized as a monophyletic group strictly on

The chat-tyrants form a well-defined group of attractive Andean tyrant-flycatchers. They are sometimes separated into two generic lineages, with a quartet of species, including ***Jelski's Chat-tyrant*** *of south Ecuador and north Peru, placed in* Silvicultrix. *These species inhabit the understorey of humid montane forest, and differ subtly from more open-country, streamside or forest-edge chat-tyrants in their plumage and voice. On the basis of these minor differences, the two groups of chat-tyrants might be sufficiently distinct to separate at the level of subgenera, but molecular evidence argues against the validity of* Sylvicultrix. *In the current work both groups are retained in the genus* Ochthoeca.

[*Ochthoeca jelskii*, Utuana, Loja, Ecuador. Photo: Doug Wechsler/ VIREO]

the basis of a unique configuration of the nasal septum. Its constituent members possess a distinctive, variously sized, transverse trabecular plate located entirely within the nasal septum. The 30 genera involved are separated from one another on the basis of cranial and syringeal characters, nesting behaviour, plumage and external morphology. Excluded from Lanyon's "*Elaenia* assemblage" is a heterogeneous group of other genera, many of which so closely resemble those within the assemblage that their inclusion within the loosely defined subfamily Elaeniinae is deemed to be justified. The huge assemblage of tody-tyrants and pygmy-tyrants is also annexed to this subfamily, though for many reasons it may be better considered a subfamily of its own, as in the past. Herein, the differences are recognized by the adoption of two tribes, Elaeniini and Platyrinchini.

Once treated as consisting of just a few species, the genus *Phyllomyias* was expanded by Traylor to encompass a number of small tyrannulets that had previously been separated into several other genera, *Xanthomyias*, *Acrochordopus*, *Tyranniscus* and *Oreotriccus*, mainly on the basis of their tarsal scutellation. The most extreme example is that of the Rough-legged Tyrannulet (*Phyllomyias burmeisteri*). For a long time, this species was even excluded by taxonomists from the family Tyrannidae because it

In the 1970s, Pogonotriccus *and* Capsiempis *were merged into* Phylloscartes *on the basis of external similarities. However, the expanded genus fell into two distinct behavioural groups: the "true"* Phylloscartes *tyrannulets, with an active foraging style, and a habit of holding the tail steeply cocked; and the bristle-tyrants, a group of more stolid species, none of which cocks its tail, and all of which have the odd, as yet inexplicable, habit of raising one wing momentarily over the back. This latter group, typified by the* ***Marble-faced Bristle-tyrant****, is returned to the genus* Pogonotriccus.

[*Pogonotriccus ophthalmicus ophthalmicus*, Nariño, Colombia. Photo: Luis Mazariegos]

*The male **Spectacled Tyrant** is unmistakable. He is mostly black with a staring eye surrounded by a swollen rosette of bare yellow skin. His wings are almost entirely white, but this only becomes clear in flight, especially during his impressive somersaulting displays. This species has unusually long legs and often runs about on the ground. Partly due to this behaviour, its position in the sequence has shifted towards the semi-terrestrial negritos* (Lessonia). *However, the pattern of plumage, sexual dimorphism and display suggest a link with the genus* Knipolegus, *with which it has traditionally been associated.*

[*Hymenops perspicillatus perspicillatus*, Depresión del Salado, Buenos Aires, Argentina. Photo: Yves Bilat]

has rough, minutely scaled tarsi, of the "taxispidean" type, whereas the exposed legs of virtually all typical tyrant-flycatchers are enclosed by a "boot" made up of an envelope that almost entirely encircles the leg, a condition known as "exaspidean". The perceived importance of this character reached its zenith in the taxonomic treatments of Ridgway, who excluded a number of otherwise quite typical flycatcher genera from the Tyrannidae strictly on the basis of their tarsal scutes. Tarsal scutellation, however, is variable across the Elaeniinae, and even varies among individuals in a number of flycatcher genera. In modern science, the exaspidean tarsus, although clearly a derived character within the Tyranni, is no longer considered to carry much useful taxonomic information within the Tyrannidae.

All of the twelve species in *Phyllomyias* are extremely similar to one another, but disagreement still exists with regard to the validity of the genus as currently constituted. All are small-bodied, green, treetop-dwelling tyrannulets with a small, rounded bill, which they use for foraging in the manner of vireos (Vireonidae), and they all regularly consume small fruits and berries. They have non-Amazonian distributions, with one group found largely in the Andes and another group in lowlands of north-eastern and south-eastern South America. The Planalto Tyrannulet (*Phyllomyias fasciatus*), the Sooty-headed Tyrannulet (*Phyllomyias griseiceps*) and the Grey-capped Tyrannulet (*Phyllomyias griseocapilla*), the three species constituting the original genus, have both cranial and syringeal features that differ significantly from those of the remaining nine species, a fact that led Lanyon to view the enlarged genus as polyphyletic.

The Yellow-crowned Tyrannulet (*Tyrannulus elatus*), the sole member of its genus, appears closely related to the seven species of *Myiopagis*, and the two genera even share internal features that suggest that they could be merged. Although these eight species look and act like miniature *Elaenia*, to the point that the merging of *Myiopagis* with the latter has been mused over by many taxonomists, internal differences strongly indicate that the two groups are not so closely related as their outward appearances would suggest.

The genus *Elaenia* is one of the largest and most uniform groups in the family. Its 18 members are nondescript, medium-sized olive-green flycatchers with a relatively small bill. Many have slightly elongated crest feathers that are raised during active calling or display, and the adults of slightly more than half of the group have a concealed white, creamy or yellowish crown patch that is revealed only when the crest feathers are erected. Virtually every forest, woodland or scrub habitat from Middle America southwards to central Argentina supports at least one species of *Elaenia*. These tyrannids are ecological generalists, sallying for insect prey both inside vegetation and in short aerial sallies over it. All *Elaenia* species regularly eat fruit. No debate exists with regard to the limits of this genus.

Ornithion, with three species, and *Camptostoma*, with two, are small vireo-like tyrannulets with a sharp, slightly curved bill and lacking rictal bristles, this last character having given rise to the name of "beardless tyrannulet" for the two *Camptostoma* forms. Early taxonomists considered the possibility of merging these genera, and the two do appear to be closely related to one another on the basis of syringeal anatomy and cranial anatomy. Their nests, however, are completely divergent. *Ornithion* builds a typical, small open cup, whereas the nest of *Camptostoma* is a large, globular affair with a side entrance, built within or against a strong support such as a crotch of a tree, a crevice within bark, or a mistletoe (Loranthaceae) or *Tillandsia* clump.

Recent observations have revealed that what was hitherto considered to be the single species in the genus *Suiriri* does, in fact, consist of two species. The Suiriri Flycatcher (*Suiriri suiriri*) has a distinctive display in which members of a pair, on separate perches close together, raise their wings and tail repeatedly while duetting with one another. The discovery of the cryptic species, named as the Chapada Flycatcher (*Suiriri islerorum*), was made when experienced field observers recognized two distinct kinds of display and accompanying duet in a region of the central Brazilian *cerrado* where the two largely allopatric forms meet.

The affinities of *Suiriri* within the Elaeniinae remain uncertain, as the taxon contains an ambiguous suite of anatomical characters, some of which align it with *Elaenia* and others with *Ornithion*. Yet another hypothesis is that this genus is closely related to the scrub-flycatcher genus *Sublegatus*, perhaps so much so that the two should be merged. Both genera are inhabitants of open woodland and dry scrub, and, besides their external similarities, the two resemble each other in certain display characteristics and in dawn song. Intriguingly, *Sublegatus* also consists of a complex of almost identical forms that have been a source of confusion to taxonomists for a century or more. Just as with *Suiriri*, fieldworkers possessing good experience of the vocal

The tyrant-flycatcher assemblage is characterized by a surplus of small greenish and brownish species. Numerically overwhelming, and visually underwhelming, they can cast the aspiring ornithologist into despondency during his or her first trip to South or Central America. With practice, however, even the dullest tyrant-flycatchers can be identified in the field. This bird pauses briefly on a tree-fern, revealing the stubby bill, short tarsus and vireo-like posture of the genus Phyllomyias. *Given that the location is the mountains of coastal Brazil, and the brownish cast to the plumage (including its wing-bars) its identity becomes clear:* ***Planalto Tyrannulet****.*

[*Phyllomyias fasciatus brevirostris*, Itatiaia National Park, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

displays of *Sublegatus* have recently detected yet another, as yet undescribed, cryptic species in this genus, in the region of Guyana and adjacent Venezuela.

It has been hypothesized that *Inezia* is related to *Sublegatus*, with which it shares syringeal and plumage characters, as well as the preference for open scrub and thicket habitats. *Inezia* is yet another genus in which, as with both *Sublegatus* and *Suiriri*, species limits were recently clarified by careful study of vocal behaviour and geography, in this case enabling the Pale-tipped Tyrannulet (*Inezia caudata*) to be separated from the Amazonian Tyrannulet (*Inezia subflava*). The Slender-billed Tyrannulet (*Inezia tenuirostris*), confined to a small area of desert scrub in northern Venezuela, is a peculiar species of uncertain affinities, and with a voice unlike that of the three other *Inezia*. It probably belongs in another genus, possibly of its own.

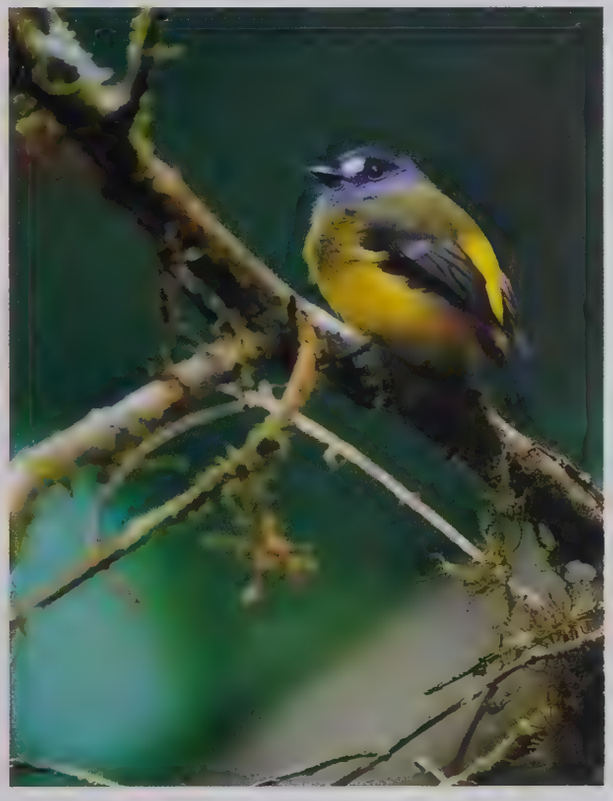
The three genera *Mecocerculus*, *Anairetes* and *Serpophaga* are usually treated as being closely related, although no definitive evidence for this relationship exists. Indeed, *Mecocerculus* itself has been referred to as a "wastebasket", as it consists of three different species groups that may not even be one another's

Members of the genus Pseudotriccus, *such as the* ***Rufous-headed Pygmy-tyrant****, forage very close to the ground in the understorey of humid montane forests. Given their sedentary lifestyle, they rarely need to flutter more than a few feet, and their wings are very short and rounded. Often highly inconspicuous, many pygmy-tyrants draw attention to themselves with high-pitched vocalizations and, in the case of this genus, a curious habit of producing snapping noises with the bill.*

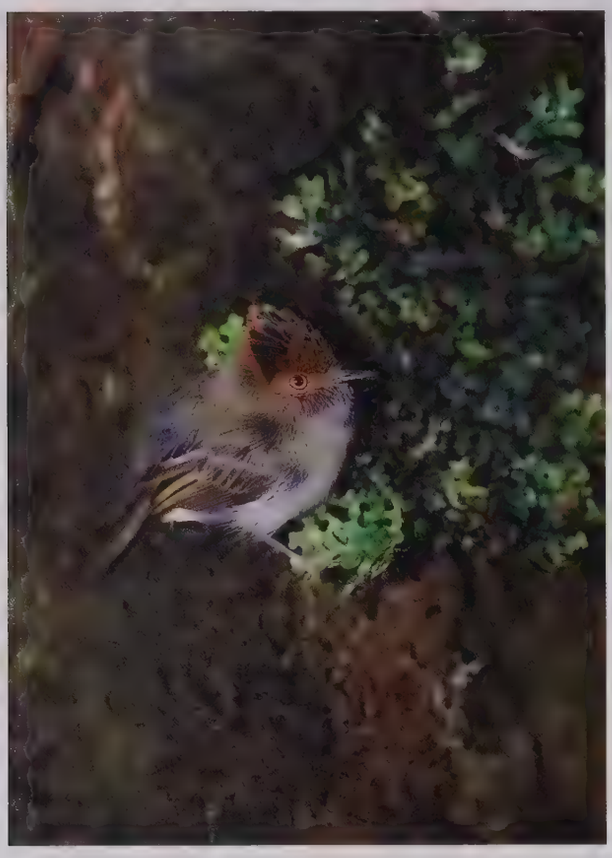
[*Pseudotriccus ruficeps*, Sierra Sabanilla, Zamora-Chinchipe, Ecuador. Photo: Doug Wechsler/ VIREO]

For decades, the antpipits were included in the gnateater family, Conopophagidae, until studies of their syringeal and cranial morphology showed them to be aberrant tyrannids. Both species in the genus Corythopis *walk about on the floor of rainforest, and sally up to snatch insects from the underside of leaves. This terrestrial lifestyle explains why the legs of the* ***Ringed Antpipit*** *are so robust. Like its congener, its presence is most often betrayed by a loud and distinctive two-note song. Sometimes these species also snap the bill repeatedly in alarm, or in communication between members of a pair near the nest.*

[*Corythopis torquatus sarayacuensis*, Zancudo Cocha, Napo, Ecuador. Photo: Doug Wechsler/ VIREO]



closest relatives. Five of its six species are small, needle-billed, warbler-like tyrannids of the temperate Andean cloudforest, where they are most frequently encountered in mixed-species flocks containing warblers, tanagers (Thraupidae), and other tyrant-flycatchers. Two of these five, the Rufous-winged (*Mecocerculus calopterus*) and Sulphur-bellied Tyrannulets (*Mecocerculus minor*), have syringeal characters that appear to unite them with *Phyllomyias*. The remaining trio of closely related species, the Buff-banded (*Mecocerculus hellmayri*), White-tailed (*Mecocerculus poecilocercus*) and White-banded Tyrannulets (*Mecocerculus stictopterus*), the first two of which form a superspecies, have syringeal and cranial features that, according to some authors, may warrant the placement of all three in a separate genus, closest to *Camptostoma* and *Ornithion*. The White-throated Tyrannulet (*Mecocerculus leucophrys*) stands apart from the other five. More robust than them, it is a long-tailed, upright-perching flycatcher that uses search-and-sally foraging in brushy habitats at the edge of the tree-line, from the high Venezuelan Andes all the way south to Argentina and Chile. Subspecific variation in this species is pronounced, and exhibits a curious pattern in which the northernmost and southernmost forms are almost identical to one another, but are separated geographically by forms that are distinctive in both size and plumage.



The eight species of *Anairetes* occupy strictly temperate or arid scrub habitats, mainly in the Andes. They are known as tit-tyrants, because their prominent crests and active, perch-gleaning foraging habits are reminiscent of those of many of the true tits and titmice (Paridae). The Agile Tit-tyrant (*Anairetes agilis*) and the Unstreaked Tit-tyrant (*Anairetes agraphia*) have a flatter crest and a longer tail and are sometimes placed in a separate genus, *Uromyias*, but genetic analysis indicates that they represent a clade within *Anairetes*. Syringeal and cranial similarities strongly support a close relationship between *Anairetes* and *Serpophaga*. The latter genus contains five species in two distinct groups. The Torrent Tyrannulet (*Serpophaga cinerea*) is one of a group of three species that are ecologically tied to rivers and streams, where they perch on boulders or muddy banks and make aerial sallies, or sally-glean for prey on other rocks, overhanging vegetation or the water surface itself.

Cocos Island, an isolated tropical Pacific Ocean island located 480 km south of Costa Rica's Osa Peninsula, is the sole home of the Cocos Flycatcher (*Nesotriccus ridgwayi*). This tyrannid occurs in a surprising variety of humid forest and brushy second-growth habitats, exemplifying "ecological release" in the presence of the reduced avifauna on this remote island, which has a surface area of only 24 km². Its bill is unusually long for its body size, and the Cocos Flycatcher's taxonomic position was enigmatic until W. E. Lanyon's studies of cranial and syringeal characters revealed its evident relationship to the aptly named Mouse-coloured Tyrannulet (*Phaeomyias murina*). The latter is a widespread and common inhabitant of lowland and lower montane arid scrub from

With its slaty head, yellow rump and white loral spot the ***Ornate Flycatcher*** *is a delightful creature. In this west Andean race the tail is mostly dark brown, but on the east slope it is fiery orange, producing an even more striking impression. It lives in pairs or small family groups in the understorey of foothill forests, often foraging conspicuously at forest borders and roadside verges. Traditionally placed alongside* Phylloscartes *in the Elaeniinae, its upright posture and active flush-chase foraging technique suggest that it is more closely related to* Myiobius *and* Myiophobus, *in the Fluvicolinae.*

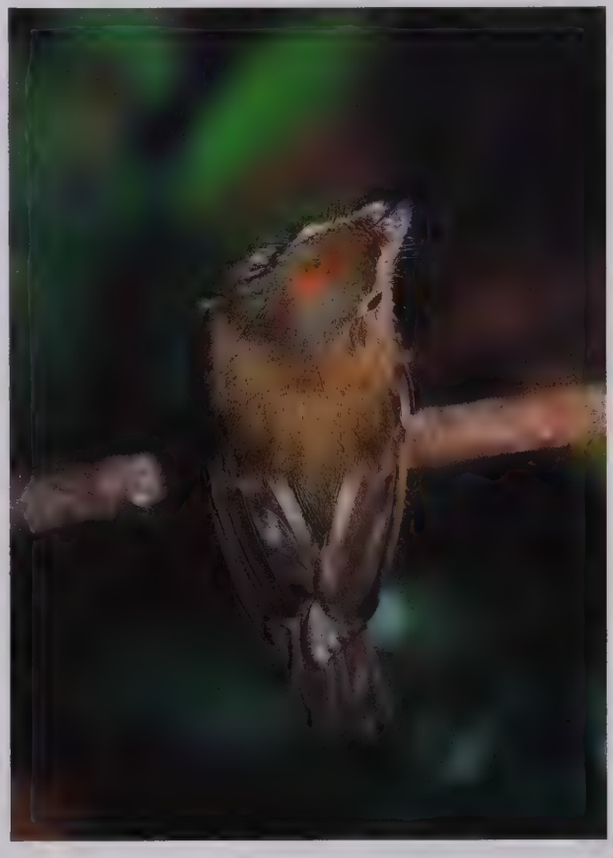
[*Myiotriccus ornatus stellatus*, La Planada Nature Reserve, Colombia. Photo: Patricio Robles Gil/ Auscape]

*The crest of the **Scale-crested Pygmy-tyrant** is hardly visible until it is fanned out and flaunted. Such displays are infrequent, and very little is known about their context. The bright crown-feathering present in many different tyrannid groups is most often directed at rivals during aggressive displays, and at potential mates during courtship. Like most pygmy-tyrants, this species is often abundant but inconspicuous, and much more readily encountered when its distinctive "police-whistle" voice is recognized.*

[*Lophotriccus pileatus squamaecrista*, Río Ñambí Natural Reserve, Nariño, Colombia. Photo: Paul Salaman/ VIREO]

Panama south throughout tropical South America, including the Pacific coast. One hopes that future DNA studies may reveal how long ago some wayward *Phaeomyias* colonized Cocos, subsequently to produce the island's distinctive endemic.

Anatomical evidence, including internal syringeal musculature, attachment of the internal syringeal cartilage, and several characters of the nasal septum, suggests a close relationship between both *Phaeomyias* and *Nesotriccus* and a third monotypic genus, *Capsiempis*, containing the Yellow Tyrannulet (*Capsiempis flaveola*); the affinities of this last, however, continue to defy resolution. Traylor merged the genus with *Phylloscartes*, and it has also been suggested that this form belongs in a group with *Inezia*. Evidence from DNA studies is eagerly awaited, in the hope that it will help to clarify the evolutionary position of *Capsiempis*.



Seven tiny, brownish tyrant-flycatcher species, currently divided among the three genera *Culicivora*, *Polystictus* and *Pseudocolopteryx*, are ecologically distinctive among the Tyrannidae in being restricted to grassland and marsh habitats. One of these, the Sharp-tailed Tyrant (*Culicivora caudacuta*), has a tail with only ten rectrices, which are stiffened and have degenerated barbs, a condition reminiscent of that found in a furnariid genus, the *Synallaxis* spinetails. Because of its distinctive tail, and in the near-absence of anatomical specimens to provide evidence for its relationships, recent authors have considered the Sharp-tailed Tyrant as *incertae sedis*, and have placed it at the end of the subfamily Elaeniinae. *Culicivora* appears to be the only tyrannid genus for which a complete skeletal specimen is lacking in museum collections, but historically it had always been listed adjacent to the two species of *Polystictus*. Until hard evidence to the contrary alters its position, it seems preferable to retain this traditional placement, which acknowledges the fact that these three species exhibit numerous, obviously derived similarities in habits, habitats and plumage colour.

Because of their outward appearance and terrestrial habits, both of which are completely unlike those of other tyrannids, the two antpipits (*Corythopis*) were long thought to be related to the gnateater genus *Conopophaga*, and the two genera were for many years united in the family Conopophagidae. Details of syringeal and cranial anatomy, however, clearly indicate that the two *Corythopis* species are highly aberrant, terrestrial tyrant-flycatchers that belong within the Elaeniinae. The Ringed Antpipit (*Corythopis torquatus*) and the Southern Antpipit (*Corythopis delalandi*) are extremely similar to one another in plumage, behaviour and voice, and could easily be treated as conspecific. Both are completely terrestrial, and while walking along the ground in the deep forest interior they physically resemble the Ovenbird (*Seiurus aurocapilla*), a parulid with a distribution mainly in North America. Rather than picking insects from the litter, however, antpipits sally upwards from the ground to snatch prey from the undersides of leaves (see Food and Feeding).

The peculiar Tawny-crowned (*Euscarthmus meloryphus*) and Rufous-sided Pygmy-tyrants (*Euscarthmus rufomarginatus*) represent another long-standing taxonomic enigma. The genus was at one time excluded from the Tyrannidae altogether, on the basis of its having taxaspidean tarsi, and it was hypothesized that it belonged with the thamnophilid antbirds. Internal cartilage in the syrinx positively identifies *Euscarthmus* as a tyrannid genus, and features of its nasal septum suggest that it belongs within a broad assemblage of *Elaenia* relatives, but other characters place it outside the subfamily Elaeniinae. The only apparently clear thing about these tiny, noisy, scrub-inhabiting flycatchers is that they are not at all closely related to the large assemblage of tody-tyrants and pygmy-tyrants. Besides their internal differences, they build weak cup-shaped nests, as opposed to the long, penduline nests typical of the latter group.

In terms of both internal anatomy and behaviour, the two wagtail-tyrants (*Stigmatura*) stand apart within the Elaeniinae. As the vernacular name implies, these species share the distinctive habit of often carrying the boldly marked tail cocked well over the back as they forage in low vegetation, often near streams. W. E. Lanyon's studies of cranial and syringeal anatomy revealed surprising similarities between *Stigmatura* and another taxonomic enigma, the Grey-and-white Tyrannulet (*Pseudelaenia leucospodia*). The latter is restricted to a small range along the arid Pacific coast of South America. Possessing a bushy crest concealing a large white crown patch, *leucospodia* had floated among several *Elaenia*-like genera, but its bill and external proportions always left doubt. Lanyon's proposal that it is a relictual relative of *Stigmatura*, deserving its own genus, is as good a taxonomic solution as any for this peculiar species.

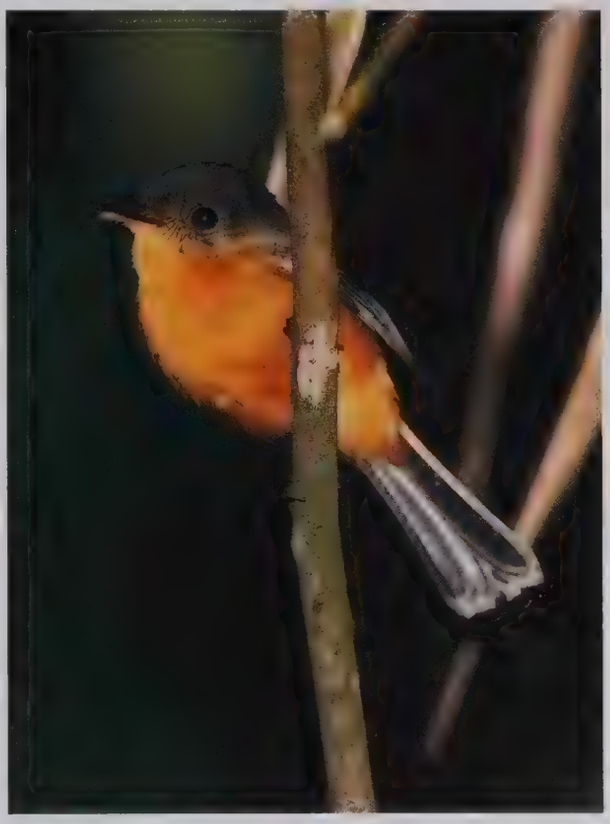
Understanding of tyrannulet relationships was advanced by Traylor, who realized that a group of species previously placed

*The spadebills are a well-defined group of inconspicuous understorey tyrannids. All have semi-concealed patches of white, yellow or orange on their crowns, as demonstrated by this **Cinnamon-crested Spadebill**. Their most distinctive feature, however, is the shovel-shaped beak, which gives them their name. Bill design relates to foraging strategy, and in this case it is the ideal tool for a bird that darts upwards from low, horizontal perches to snatch insects and spiders from the underside of leaves. Species that feed like this also tend to have prominent rictal bristles.*

[*Platyrinchus saturatus saturatus*, Trinité Natural Reserve, French Guiana. Photo: Olivier Tostain]

*When not displaying, the **Royal Flycatcher** is a retiring and unremarkable inhabitant of the dark forest understorey. It is a short-legged, mouse-coloured bird with a pale rump and a slightly "hammer-headed" look. On closer inspection, the broad-based bill seems unusually long, tipped with a prominent hook and surrounded by lengthy rictal bristles (modified feathers). These almost cat-like whiskers are the longest in the family. Only in display, however, is the bird's real secret revealed. Each feather of the crest is greatly elongated, yellowish-orange in the female, scarlet in the male, and tipped with iridescent violet-black. This crest is fanned out vertically and laterally to produce a peacock-tail of vivid colour. To accentuate the impression, the mouth is usually opened to show a bright orange lining, and the head is tipped from side to side in a steady mechanical fashion. It is postulated that this display occurs in courtship and during intra-sexual competition, but it is very rarely seen in the field. In general day-to-day behaviour, the crest is furled and almost invisible. The Royal Flycatcher is polytypic, and possibly made up of three separate species. The form pictured here is often split as a separate species, then referred to as the "Atlantic Royal Flycatcher" and classified as Endangered because of its low-density population, patchy distribution and the continuing destruction of the Atlantic Forest.*

[*Onychorhynchus coronatus swainsoni*, Marumbi State Park, Paraná, Brazil. Photos: Haroldo Palo Jr.]



Empidonax *is a North American radiation of small sally-gleaning, upright-perching species with broad-based bills. Several, including the* ***Acadian Flycatcher****, have relatively long wings, as a result of their migratory lifestyle. Although most members of* Empidonax *are notoriously bereft of distinctive morphological characteristics, a good knowledge of subtle field marks, behaviour (especially song) and moult pattern is sufficient to identify all species. A few species are so similar that some individuals cannot easily be distinguished, even in the hand, and are best separated by voice on the breeding grounds.*

[*Empidonax virescens*, Michigan, USA. Photo: Dave Maslowski/ Maslowski Productions]

in "*Tyranniscus*", one of several genera that he subsumed in *Phyllomyias*, displayed both plumage and anatomical peculiarities meriting generic recognition. He named the group *Zimmerius*, in honour of the meticulous taxonomist, J. T. Zimmer, who had first commented on this species group. Anatomically, *Zimmerius* is more closely allied with *Phylloscartes* than it is with the tyrannulets that it superficially resembles, such as those in the genus *Phyllomyias*. In 2001, a distinctive, small-bodied *Zimmerius* species was described from the scrubby, white-sand forest of north-eastern Peru. This odd species, named as the Mishana Tyrannulet (*Zimmerius villarejoi*), appears to be a diminutive relative of the Red-billed Tyrannulet (*Zimmerius cinereicapilla*) of the forested southern Peruvian foothills. The discovery solved a long-standing mystery, as a specimen of this tiny *Zimmerius* had sat for ages in the museum trays of Chicago's Field Museum of Natural History, in the USA, where it had long been suspected to represent an undescribed taxon. Zimmer himself had puzzled over it, and it took the astute hearing of J. Álvarez Alonso and B. M. Whitney to detect an unfamiliar voice in the field and bring to light the identity of this new species.

Treatment of the genus *Phylloscartes* has varied in recent decades. In 1979, with publication of Volume 8 of Peters's checklist, the genus was enlarged to encompass the *Pogonotriccus* bristle-tyrants and even, as mentioned above, the peculiar Yellow Tyrannulet, until then generally placed in the monotypic genus *Capsiempis*. Indeed, when examined in the museum tray, the 24 species involved are surprisingly similar in form and plumage pattern. All are relatively long-tailed and thin-billed, and have rictal bristles that are moderately to well developed; most are bright olive-green above, with prominent wingbars and superciliary stripes, and many have a contrasting facial pattern that includes auricular patches or crescents, as in *Leptopogon*. With the single exception of *Capsiempis*, all are birds of lower montane moist forest. In more recent years, the expanded *Phylloscartes* has been considered universally by specialists in the field as being an unnatural, behaviourally heterogeneous group. Most conspicuously different is *Capsiempis*, consisting of a single, polytypic, locally distributed species occupying dense, tangled, viny or bamboo habitats in tropical lowlands. Its bill is broader, its crown is bushy and occasionally raised into a loose crest, and its tail is occasionally cocked, but otherwise its foraging behaviour is less gnatcatcher-like than is that of typical *Phylloscartes*. *Capsiempis* also has a distinctive social system, with members of the pair often giving a variety of mellow whistled notes and burry, nasal calls that are quite different in quality from the thin, high-pitched chatters uttered by *Phylloscartes* and *Pogonotriccus*. The latter two genera are separated principally on the basis of behaviour, although there seems little doubt that DNA analyses will ultimately bear out the existence of this division within the group.

The 16 species that remain in *Phylloscartes* forage extremely actively, and they do so in the outermost or uppermost vegetation of the forest canopy. The tail is held at or above the horizontal and is occasionally cocked almost vertically over the back, sometimes being flicked upwards once per second and fanned slightly. During active foraging the wings are held out and slightly opened, or flicked outwards repeatedly with the same rhythm as the tail-flicking. The bird itself sometimes flits from side to side as it moves out along a branch, at times even reversing 180 degrees with each flit. Perch-gleans and short-distance outward

The genus Contopus *is one of only four tyrannid lineages whose main radiation is in North or Central America. Seven species breed from Costa Rica northwards, and only three in South America. Their long wings are adapted for aerial prey-capture. The northern forms tend to be migratory, and have even longer wings. The* ***Lesser Antillean Pewee*** *is a resident Caribbean form, with relatively short primaries to match. Like its congeners, it has a very long and broad bill, well-developed rictal bristles, and rather slender tarsi, ideal for a sit-and-wait predator of flying insects. The nominate race is sometimes treated as a separate species.*

[*Contopus latirostris latirostris*, St Lucia, West Indies. Photo: Roland Seitre]

hover-gleans or snatches are frequent. Members of the group recognized as the genus *Pogonotriccus*, comprising the seven bristle-tyrants, forage in a very different manner, typically perching for 10-30 seconds within shaded areas well below the forest canopy, sometimes within a few metres of the ground. These tyrannids, typified by the Spectacled Bristle-tyrant (*Pogonotriccus orbitalis*), appear "large-headed", have an upright stance, and hold the tail pointing vertically downwards; occasionally, they flick one wing high over the back for an instant, a peculiar display shared with *Leptopogon* and *Mionectes*. Bristle-tyrants make upward-directed sally-strikes or upward hover-gleans.

Leptopogon and *Mionectes* share a number of characters that suggest that they are closely related. *Leptopogon* species are not quite so frugivorous as are those in *Mionectes*, but they do regularly eat fruit and have sometimes even been found to have the stomach entirely filled with melastome (Melastomataceae) berries. The two genera also have in common a somewhat unusual nest form (see Breeding). In addition, members of both have the peculiar habit of rapidly lifting one wing straight upwards for an instant while sitting, otherwise motionless, on a perch, a type of behaviour also exhibited by the seven bristle-tyrants in the genus *Pogonotriccus* (see General Habits).

The five species presently constituting the genus *Mionectes* are the most frugivorous of all the tyrant-flycatchers. These are birds of the forest understorey, where they may forage for insects on their own or with mixed flocks, but even more often are found together with manakins around copiously fruiting understorey shrubs or trees, such as melastomes. *Mionectes* is clearly composed of two groups, or subgenera: two species of "true" *Mionectes* that are dark olive overall, with streaked underparts; and three ochraceous-bellied species, typified by the Ochre-bellied Flycatcher (*Mionectes oleagineus*), formerly constituting the genus *Pipromorpha*. Besides sharing numerous characters, both internal and external, the five species in this genus appear to be unique among the Tyrannidae in that the males sing and display at leks (see Breeding).

Yet another monotypic genus of uncertain affinities is *Myiotriccus*. With its black head, bright yellow crest, chestnut tail, and egg-yolk-yellow rump tufts and underparts, the Ornate Flycatcher (*Myiotriccus ornatus*) is one of the most beautiful of all tyrannids. It lives in subtropical Andean forests, where it frequents dark, moist ravines laden with tree-ferns. It is often seen alone or in pairs, making its presence known through the incessant uttering of a loud "pyip" call, but it also moves with mixed-species flocks that pass through its territory. With acrobatic aerial sallies and flush-chases from enclosed perches, it contributes spectacular yellow flashes to some of the darkest interior habitats of the wet Andean foothills. *Myiotriccus* has been allied to the *Phylloscartes* group on the grounds of its syringeal and cranial morphology, but few, if any, fieldworkers find it easy to accept such a grouping. The upright stance, search-and-sally foraging behaviour and concealed bright yellow crown patch of *Myiotriccus* are strongly reminiscent of two genera in the subfamily Fluvicolinae, *Myiophobus* and *Myiobius*, either one of which would appear to be an equally plausible relative of this distinctive species.

One of the most bizarre and most specialized of all tyrant-flycatchers is the Many-coloured Rush-tyrant (*Tachuris rubrigastra*), a species entirely restricted to dense rushes and reeds. It has an extremely slender bill, a slight crest, and quite long legs with strong feet, adapted for perching on the vertical stalks of its marshy habitat. In colour and behaviour, *Tachuris* is unlike any other tyrannid; the bright red crown, blue face, red undertail-coverts, and white flashes on the wings and tail present a startling, harlequin-like pattern of colour among dense reeds. The voice is equally peculiar, consisting of a rapid series of insect-like, unmusical "tic" notes offered from midway up a reed or while the bird flies weakly over the rushes. Internal anatomy provides no insight into the origins or affinities of this most unusual flycatcher, and its nest is equally unique among the Tyrannidae (see Breeding). The evolutionary history and phylogenetic position of *Tachuris* remain mysterious, but the possibility that it represents a colourful offshoot of the marsh-dwelling *Pseudocolopteryx* radiation should be investigated. For the present, *Tachuris* continues to be listed adjacent to other narrow-billed elaeniine genera simply for lack of evidence suggesting any better place within the subfamily.

The smallest-bodied flycatchers make up a remarkable group of 52 species, almost one eighth of the entire family, and the bulk of the tribe Platyrinchini. They are currently treated in eight genera known collectively as the tody-tyrants, which also include the pygmy-tyrants, the tody-flycatchers and the bentbills. These uniformly tiny flycatchers have a disproportionately long bill, in most cases spatulate-shaped, and long, slender tarsi. So far as is

In a family famed for dull coloration, the ***Vermilion Flycatcher*** *stands out from the crowd. The male's crown and underparts are vivid vermilion-red, making him visible from a great distance as he perches prominently and sallies after flying insects. The female is much duller, streaked with brown and white and having only a faint tinge of pink below. This species occurs from the southernmost states of the USA to northern Patagonia, and as far afield as the Galapagos Islands. It usually breeds in open country, but in the non-breeding season it is commonly found over riverbanks and along the brushy shores of ox-bow lakes in Amazonia.*

[*Pyrocephalus rubinus*. Photo: A. & E. Morris/ Birds as Art/Windrush]

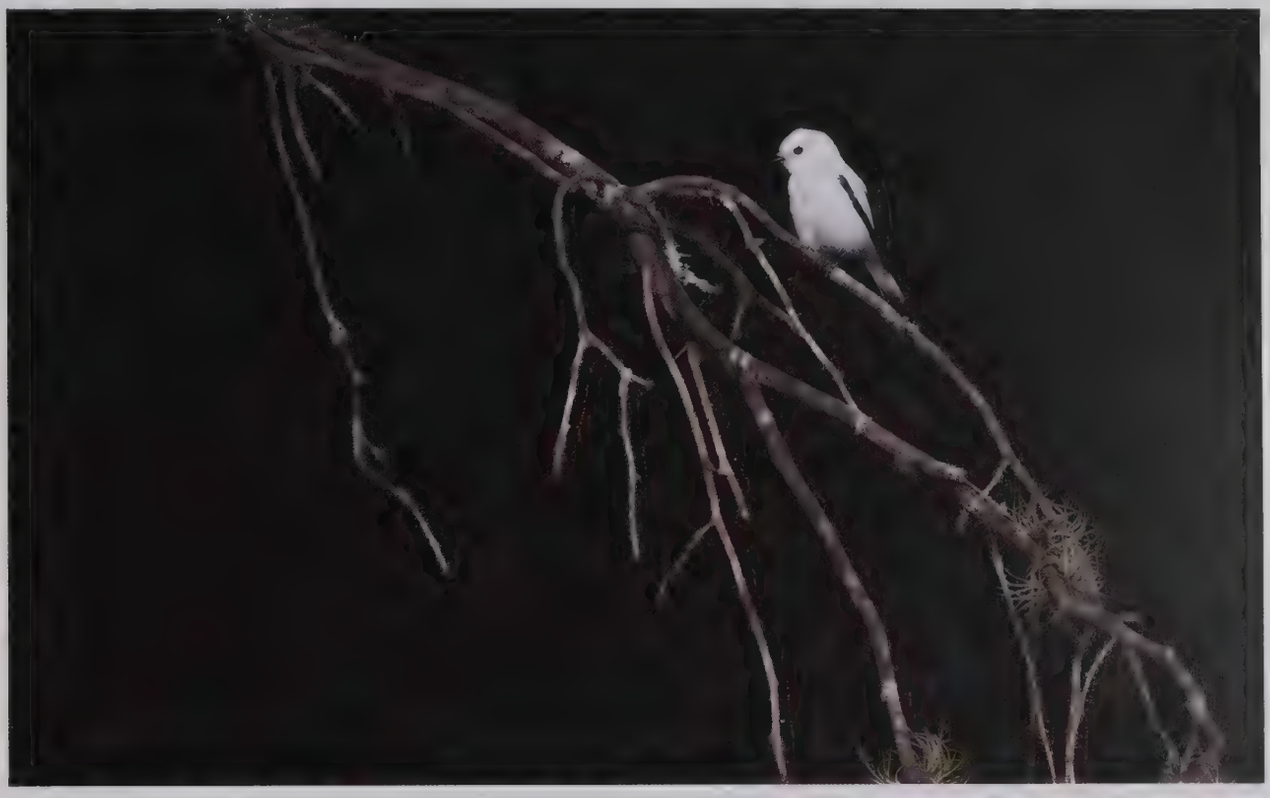
known, every one of them builds a purse-like, pendent nest with a side entrance. Their upward-striking foraging behaviour is as stereotyped as that of any tyrannid lineage. Indeed, apart from minor differences in plumage and bill form, the members of this group are all remarkable replicas of one another, a fact that has several ecological implications (see Habitat).

Myiornis, the first of the tody-tyrant genera, contains the world's smallest passerine birds, the closely related Short-tailed (*Myiornis ecaudatus*) and Black-capped Pygmy-tyrants (*Myiornis atricapillus*). They have an average wing length, measured from the bend of the wing to the tip of the longest primary, of about 33 mm. With such tiny, rounded wings and almost no tail, these birds move about with extremely rapid wingbeats in a strange, hovering style of flight that presents the impression of a medium-sized beetle (Coleoptera), rather than a flycatcher.

The Pale-eyed Pygmy-tyrant (*Atalotriccus pilaris*), although placed in a monotypic genus, is closely related to the four *Lophotriccus* species, but it is an inhabitant of scrub and dry woodland, and it lacks the peculiar, laterally orientated crest typical of *Lophotriccus*. Further, it differs from other tyrannids in having its four outer primaries greatly reduced and narrowed, such that they barely resemble wing feathers at all. This structural modification functions, in a still unknown way, in producing the strange wing-buzzing made by this species during its breeding-season display. A similar, and even more specialized, structure of the outer primaries has been shown to be associated with wing-buzzing displays in the doradito genus *Pseudocolopteryx*.

Over the past two decades, the tody-tyrant genus *Poecilotriccus* has undergone considerable enlargement. Originally, the generic name was restricted to the montane Rufous-crowned Tody-tyrant (*Poecilotriccus ruficeps*), a species with a spectacular and anomalous plumage pattern consisting of a bushy, chestnut crown, a yellow wingstripe and a black breastband. Several of these plumage features do also appear in the lowland forms later transferred from *Todirostrum* to *Poecilotriccus*, such as the sexually dimorphic Black-and-white Tody-tyrant (*Poecilotriccus capitalis*) and its close relative the White-cheeked Tody-tyrant (*Poecilotriccus albifacies*). A number of additional species long treated within the genus *Todirostrum* were then moved into the enlarged *Poecilotriccus*, on the basis that they shared the same distinctive syringeal structure; one such example is the Slate-headed Tody-flycatcher (*Poecilotriccus sylvia*). Finally, a beautiful new species, closely related to the Rufous-crowned Tody-tyrant, was described only recently from the slopes of the Marañón Valley, in north-east Peru. It has been named Johnson's Tody-tyrant (*Poecilotriccus luluae*).

The remarkable Black-chested Tyrant (*Taeniotriccus andrei*), still rare in museum collections and until very recently almost unknown in life, had been lumped in the genus *Poecilotriccus* largely on the grounds that it shared plumage similarities and sexual dimorphism with, especially, the Black-and-white Tody-tyrant. *Taeniotriccus*, however, is significantly larger and has an extraordinary, bushy rufous crest with black central feathers, surrounded by a "ruff" of elongated feathers on the nape and sides of the neck. A spray of elongated, stiffened black feathers almost surrounding the eye, and exaggerating its apparent size in life, is unique among the tody-tyrants. K. J. Zimmer and A. Whittaker, who recently discovered this species' presence in eastern Brazil, were able to record that it has a simple, nasal voice, unlike that of all members of *Poecilotriccus*.



One of the largest genera in the family, *Hemitriccus* numbers 21 species. For a long period, it had been restricted to just three bamboo-inhabiting species with modestly reduced outer primaries, but the genus now encompasses a homogeneous group of pygmy-tyrants many of which, because of morphological idiosyncrasies, had formerly borne generic names of their own. The Boat-billed Tody-tyrant (*Hemitriccus josephinae*), for example, because it has a bill slightly wider than that of the others, was previously placed in *Microcochlearius*. Likewise, Snethlage's Tody-tyrant (*Hemitriccus minor*) was generically separated from the rest on the grounds that its nostrils are distinctively rounded, a character present also in the Yungas Tody-tyrant (*Hemitriccus spodiops*). The Fork-tailed Pygmy-tyrant (*Hemitriccus furcatus*), because of its forked tail with only ten rectrices, all tipped white, was formerly given a separate genus, *Ceratotriccus*. It could be argued that the bentbill genus *Oncostoma*, currently listed next to *Myiornis*, should also be merged with *Hemitriccus*, as its principal generic peculiarity, mentioned in the English name, is simply a minor variation on the pygmy-tyrant theme.

All *Hemitriccus* species are small, brownish-olive to greenish-olive birds with variable striations of olive on the breast, and sometimes washed rusty about the head and throat. The bill is long and slightly spatulate, but not so wide as that of *Todirostrum*. The "brown group" contains six species that have a classic relict

The genus Knipolegus *is a well-defined collection of ten species, most of which are black in the male and brownish in the female. Sexual dimorphism is less pronounced in a few species, such as the* ***Velvety Black-tyrant****, in which the adult female is identical to the male except for the chestnut streaking on her throat, as seen here. Most* Knipolegus *species are conspicuous aerial foragers that perch prominently on low vegetation. Many are migratory: this species undertakes altitudinal movements in coastal Brazil, breeding at the edge of upland forests and descending in winter to open foothill country.*

[*Knipolegus nigerrimus*, Itatiaia National Park, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

The genus Xolmis *is largely restricted to southern Brazil, Bolivia, Paraguay and Argentina. The* ***White Monjita*** *is immaculately, almost luminously, white. It is also known by the name of "ghost bird", not only on account of its ethereal plumage, but because of its habit of perching on headstones in country graveyards. Of course, monjitas will use many perches, including wires, fences, boulders and pylons, indeed any high, open vantage point from which they are able to hunt. They drop to the ground to seize their prey, or snatch it in aerial sallies, often returning to the same perch.*

[*Xolmis irupero irupero*, Río Pilcomayo National Park, Formosa, Argentina. Photo: José & Adriana Calo]

distributional pattern surrounding, but not including, the Amazon Basin. Most remarkable is the complex of three closely related species occupying moist highland forest in three tiny ranges thousands of kilometres apart from one another. These are the Cinnamon-breasted Tody-tyrant (*Hemitriccus cinnamomeipectus*) of the equatorial Andes, the Buff-breasted Tody-tyrant (*Hemitriccus mirandae*), living in the isolated hills of north-eastern Brazil, and Kaempfer's Tody-tyrant (*Hemitriccus kaempferi*), confined to the hills of extreme south-eastern Brazil.

The genus *Todirostrum* is now restricted to a group of seven species that appear to be unquestionably monophyletic. Each has a bill more than one-third the length of the wing, and with long parallel sides and an almost squared tip, producing a spatula-like shape that is indeed convergent on the bill of the true todies (*Todus*). They all forage by making predominantly upward strikes, and their voices are restricted to nasal "tic" notes and chirps. This genus is unusual among small tyrannids in the well-developed vocal duetting performed by members of a mated pair. In parks and shrubby pastures, the Common Tody-flycatcher (*Todirostrum cinereum*) is frequently seen to give an odd display: holding the wings drooped and the tail cocked vertically over the back, the bird hitches sideways along a perch while ut-

The ***Cattle Tyrant*** *is a widespread and familiar South American bird, but it is also a genuine taxonomic enigma. Its plumage resembles the yellow-bellied kingbirds* (Tyrannus)*, even down to the coronal patch, and its display also resembles that of the kingbirds. But unlike kingbirds, it is usually terrestrial, making short flights after insects, or probing in short grass for insects. In rural areas it often feeds around (or on top of) livestock. Of course, this trick predates the arrival of cattle, and presumably was practised on a number of the larger native mammals, such as the capybara* (Hydrochaeris hydrochaeris).

[*Machetornis rixosa rixosa*, Pantanal, Mato Grosso, Brazil. Photo: Fabio Colombini]

Highly elongated rectrices have arisen on at least four separate occasions in the family. In Tyrannus, *for example, the Fork-tailed Flycatcher* (T. savana) *and* ***Scissor-tailed Flycatcher*** *have very long outer tail feathers. This feature led to their separation in the genus* Muscivora, *but they are otherwise typical kingbirds. Both species catch insects in flight, and it is possible that the exceptional outer tail feathers supply extra aerial manoeuvrability, just as it does for swallows. In addition, these fancy tails are shown off during courtship behaviour, and they are presumably favoured to some extent by sexual selection. As in* Hirundo, *tails average much longer in males than in females.*

[*Tyrannus forficatus*, near Amarillo, Texas, USA. Photo: Wayne Lankinen/ DRK]

tering a series of sharp "tic" sounds. Its two allopatric relatives, the Maracaibo Tody-flycatcher (*Todirostrum viridanum*) of the Venezuelan coastal scrubs and the Grey-headed Tody-flycatcher (*Todirostrum poliocephalum*) of south-eastern Brazil, give the same display.

Nine species, collectively known as flatbills, make up two distinctive genera, *Rhynchocyclus* and *Tolmomyias*, which share a number of internal characters, in addition to the distinctively stout, laterally swollen, shovel-shaped bill. These two genera differ in a few syringeal characters and in egg colour, but they also have in common several anatomical features that support the argument that they should continue to be treated as each other's closest relatives. They are species of forest and dense scrubby woodland, and they share several unique behavioural quirks. The nests of both genera, although different in detail, are pendent and ball-shaped, with a recurved, downward-protruding entrance tube, and are regularly placed near active wasp nests. Most peculiarly of all, species in both genera use their nests as temporary roosts or domiciles even outside the breeding season. No other tyrannids are known to utilize their nests in this manner.

With 22 species currently recognized, the genus Myiarchus *is numerically diverse but morphologically homogeneous.* ***La Sagra's Flycatcher*** *is a typical example: brown above, pale below, with a fairly long tail and well-marked pale edges to the wing coverts and inner flight-feathers. Its bill is quite large and slender, an ideal tool for snatching large insects off vegetation in flight or while hovering. Many* Myiarchus *species have longer primaries, but this Caribbean form is resident or only modestly migratory, and its wings are relatively short. Given the extreme similarity across this entire genus, voice and geographical location provide the best clues to identify different species.*

[*Myiarchus sagrae sagrae*, Cayman Islands. Photo: Roland Seitre]

Attilas are unusual tyrannids, and as a result they have spent much of their taxonomic history outside the family. They are robust birds with loud, distinctive songs. The bill is large and strongly hooked. The face is covered with stiff rictal bristles, presumably to protect their eyes against the flapping wings, barbed legs and noxious, urticant hairs of their prey. They are usually found in the middle storey and canopy, but often come low, like this ***Grey-hooded Attila****, to search for food in the understorey or even occasionally on the ground.*

[*Attila rufus rufus*, Intervales, São Paulo, Brazil. Photo: Edson Endrigo]

The legendary T. A. Parker, when he heard an unfamiliar song from the forested river margins along the Amazon River, correctly diagnosed the presence of a previously undetected species of *Tolmomyias*. The new taxon, the Orange-eyed Flycatcher (*Tolmomyias traylori*), was given its scientific name for the great Chicago taxonomist who had comparatively recently completed his exhaustive review of the family. Prior to this discovery, and ironically, two specimens of the new species had been overlooked for decades in the drawers of Traylor's own Field Museum.

It is quite likely that no genus in the Tyrannidae still contains more cryptic species awaiting analysis and detection than does *Tolmomyias*. Special attention should be paid to the Yellow-olive Flycatcher (*Tolmomyias sulphurescens*), in which pronounced variation in vocal behaviour between Middle America and southern Brazil suggests that as many as four or five species could be involved. Although less pronounced, geographical variation in the voices of the widespread Yellow-breasted (*Tolmomyias flaviventris*) and Yellow-margined Flycatchers (*Tolmomyias assimilis*) also warrant careful comparative study.

For a century or so, the exclusively South American genus *Ramphotrigon* was treated as another representative of the flatbill assemblage. Its three species are, however, cavity-nesters, and their internal anatomy, including, for instance, a nearly fully ossified nasal capsule with internal supporting rod, confirms that they are, in fact, members of the *Myiarchus* assemblage in the well-delineated subfamily Tyranninae. The convergence of *Ramphotrigon* with the flatbills with regard to bill morphology attests to the power of evolutionary forces that favour spatulate bills among upward-striking insectivorous birds the world over (see Morphological Aspects).

It is worth emphasizing that the phylogenetic placement of the flatbill and tody-tyrant assemblage as defined by Lanyon remains equivocal. Credible tree-configurations exist whereby this large clade is basal at least to the family Tyrannidae, and possibly to the entire suborder Tyranni (as here defined). Some, though not all, of these species share a largely unossified nasal capsule, and all build distinctive, pendent nests. It is intriguing, too, that the putative phylogeny of Sibley and Ahlquist, based on DNA-DNA hybridization, places at least a portion of this assemblage in its own subfamily, Mionectinae; indeed, these authors felt that this upper-level taxon met their criteria for family status. Nevertheless, as many pygmy-tyrants do have an ossified nasal septum, including a broad trabecular plate, it may be that the loss of this state in certain species and genera carries little phylogenetic information. For the present, placement of the flatbill and tody-tyrant assemblage within the Tyrannidae, adjacent to the more typical Elaeniinae, remains the preferred, conservative treatment, though the acknowledged differences between them are indicated by the recognition of two tribes.

Despite this, if construction of a hanging nest is viewed as a definitive character for the flatbill and tody-tyrant clade, then the remarkable spadebills (*Platyrinchus*) must be excluded, as the three spadebill species for which nests have been documented all build delicate cup-shaped structures at the fork of a branch. On the other hand, syringeal evidence suggests at least a distant affinity with the flatbills, and the spadebills' unique bill shape, with the largest breadth-to-length ratio of all the tyrant-flycatchers, is approached by *Rhynchocyclus* and *Tolmomyias*. Spadebills inhabit the dark forest understorey, where they perch on bare horizontal twigs and, at long intervals, make explosive upward sallies to strike at insects on the undersides of leaves. Typically, most tropical and subtropical forests of Middle and South America support only a single spadebill species, although two species do occur together in tall forest habitats of the western Amazon Basin. The White-crested Spadebill (*Platyrinchus platyrhynchos*) is the largest in the genus, and it forages significantly higher up in the forest understorey than does the smallest species, the Golden-crowned Spadebill (*Platyrinchus coronatus*). The rare Cinnamon-crested Spadebill (*Platyrinchus saturatus*) appears to occur mainly in white-sand forest and scrub.

The highly distinctive Royal Flycatcher (*Onychorhynchus coronatus*) is a slender, buffy-brown flycatcher with unusually short legs, and possesses a very long flattened bill very much like that of a giant tody-tyrant. Its remarkable rictal bristles, the longest in the family, reach the tip of the oversized bill. The feature for which this bird is best known, however, is its elongated and fan-shaped crest, bright scarlet in the male, yellowish-orange in the female, with each feather tipped with iridescent violet-blue. The crest features in a bizarre and unique display (see General Habits).

As species limits of tropical American birds become better understood, the complex of Royal Flycatcher forms currently treated as representing a single, widespread species will prob-

Becards are a distinct group of South and Central American species that only barely sneak into the USA. They are noted for their robust bills, sexual dimorphism, and a highly modified ninth primary. In some species this feather is much shorter than its neighbours and abruptly emarginated near the tip. It presumably functions in sound production during a wing display, but this has not been confirmed. The ***Green-backed Becard*** *is like most of its relatives in that it is a bird of lightly wooded country and the canopy of more extensive forests, it regularly joins mixed-species flocks, and it is most easily tracked down by its voice.*

[*Pachyramphus viridis viridis*,
Intervales,
São Paulo, Brazil.

ably be reinterpreted. Most likely to be elevated to the status of a full species may be the subspecies *occidentalis*, restricted to the disappearing dry and semi-humid forests of the Pacific lowlands of west Ecuador and north-west Peru. Both this and the almost unknown Atlantic subspecies, *swainsoni*, confined to a few remnant patches of Atlantic Forest in south-east Brazil, have been treated as full species by several recent authors, and both taxa are listed as globally threatened (see Status and Conservation).

The systematic position of *Onychorhynchus* remains uncertain, as it shares a mosaic of characters with the flatbills, with *Cnipodectes*, with the spadebills and with *Myiobius*. The highly unusual shape of its internal syringeal cartilage is mirrored only by *Platyrinchus*, and the broad bill, unusually long rictal bristles, colourful crown patch and "large-eyed" appearance further suggest that genus. The Royal Flycatcher's remarkably long, hanging nest, however, is totally unlike that of the spadebills, and is most similar to that of the next genus, *Cnipodectes*.

The final member of the subfamily Elaeniinae is the Brownish Twistwing (*Cnipodectes subbrunneus*), alternatively known by the rather less imaginative name of "Brownish Flycatcher". The strange, rotated outer primaries of the adult male (see Morphological Aspects) are its most distinctive feature, whereas there are certainly plenty of flycatchers that are brownish. The taxonomic placement of this odd species within the Tyrannidae is uncertain, but syringeal evidence suggests a relationship with *Onychorhynchus*, and the two also construct the largest hanging nests of any member of the family. Mysteries surrounding *Cnipodectes* have grown considerably with the recent discovery of a highly distinctive new species apparently belonging to this genus. It is a medium-sized, bright cinnamon flycatcher with a bold red-orange iris, and was found in bamboo forest near the Manu River, in south-eastern Peru.

Approximately 130 species comprise Traylor's subfamily Fluvicolinae, a group that differs in only minor detail from Lanyon's "*Empidonax* assemblage". This group is defined primarily by a distinctive, well-ossified nasal septum having a basal trabecular plate bearing an anterior, unossified notch, and ending posteriorly in a V-shaped or Y-shaped fork. This character is found in all but three fluvicoline genera, and nowhere else in the Tyranni.

Fluvicolinae represents by far the most widely varied tyrannid group in terms of the size, form, foraging habits and ecology of its species. Two principal lineages form the bulk of this subfamily. One of these consists of forest and woodland species, most of which are sally-gleaners and aerial hawkers, foraging within the dark interiors or open edges of tall forest, where they use the relatively wide bill bordered by long rictal bristles to snap up arthropod prey. The second lineage contains a wide diversity of species, the centres of radiation of which have been the dry open country south of Amazonia and the temperate grassland of the

Highly migratory tyrannids, such as the ***Western Kingbird****, tend to have long wings. Some of the most impressive migrations are undertaken by kingbirds, and these birds show distinctive morphological adaptations for both powerful aerial sallies and long-distance journeys. Their primaries are markedly notched on the inner web, and the tips of the outer primaries are long and narrow due to sharp attenuation. These characteristics (clearly visible here) echo the wing structure of many raptors, and are believed to improve the efficiency of sustained high-velocity flight.*

Maslowski Productions]

In the avian paradise that is South America, a host of tiny-bodied, short-winged species bear the name "tody-tyrant" or "pygmy-tyrant". In some sites several of these species occur side by side, with finely tuned ecological separation. Most of them are birds of humid forests, and the ***Eared Pygmy-tyrant*** *is no exception. Its range is centred on Brazil's Atlantic Forest, where it occupies most levels from the low understorey to the subcanopy.*

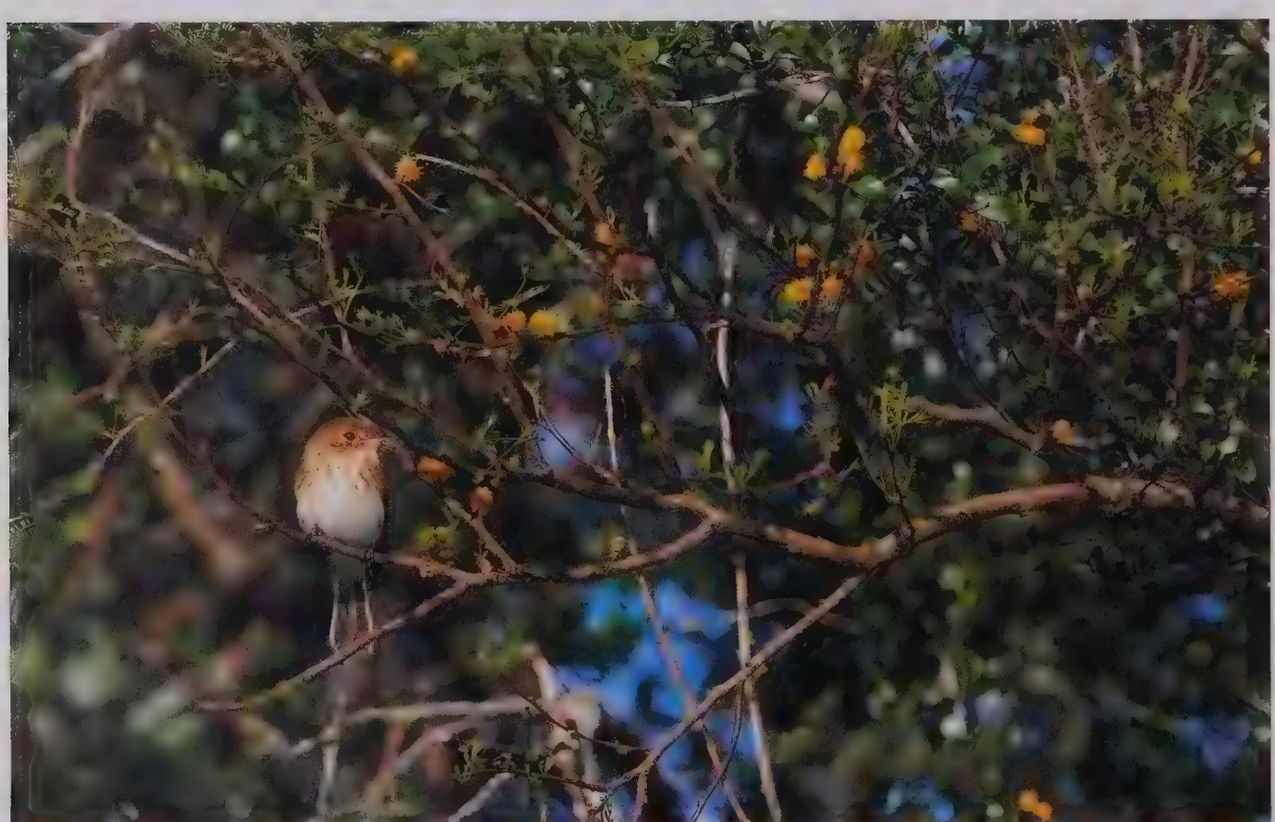
[*Myiornis auricularis auricularis*, Intervales, São Paulo, Brazil. Photo: Edson Endrigo]

southern Andes. Herein, these groups are recognized as two tribes, respectively Contopini (see pages 25-27) and Fluvicolini. Despite the ecological and morphological diversity of the subfamily Fluvicolinae, it does appear to be a well-defined group on the basis of a number of cranial and syringeal characters, and DNA-sequence data now further support the contention that some portions of the subfamily are monophyletic lineages. Comparative analyses of behaviour and body shape reveal several important behavioural and morphological pathways along which this large radiation has evolved.

Myiophobus and *Myiobius* are at present placed at the transition between the flatbills and the *Empidonax*-like tyrannids. The first, *Myiophobus*, is discussed below. Members of the distinctive, enigmatic genus *Myiobius* share numerous characters with *Onychorhynchus*, including unusually long rictal bristles, large eyes, a colourful crown patch, an ossified interorbital septum,

Most tody-flycatchers are birds of brushy country, low, dry forests and shrubland, but the ***Yellow-browed Tody-flycatcher*** *has adapted to the high canopy of humid forests. These birds get their name from a vague similarity to the coraciiform family Todidae. The genus* Todirostrum *is a monophyletic grouping of seven species, all with the same flattened, spatula-shaped bills. Being so small, and living so high above the ground, this particular form very easily passes undetected until its quiet insect-like ticking song is recognized.*

[*Todirostrum chrysocrotaphum*, ExplorNapo Lodge, Iquitos, Peru. Photo: Jordi Bas]



*The **Large-headed Flatbill** is one of more than 80 species of tyrant-flycatcher that co-occur at some sites in south-eastern Peru. This staggering total, the highest congregation of birds belonging to a single family anywhere on the planet, is made possible by narrow niche segregation in a complex habitat mosaic, including mature rainforest, early successional forest along floodplains, and associated wetlands. This species, for example, is locally common in bamboo-dominated forest, and rarely seen away from bamboo.*

[*Ramphotrigon megacephalum bolivianum*, Manu National Park and Biosphere Reserve, Madre de Dios, Peru. Photo: Bernard van Elegem]

and an unusual, derived syringeal character of two fully ossified anterior rings (or A elements) at the head of each bronchus; both genera also build hanging nests. Unlike the Royal Flycatcher, however, all *Myiobius* species practise a mode of foraging that is unique in the Tyrannidae, and reminiscent of that of the American Redstart (*Setophaga ruticilla*). The broad full tail is spread horizontally and the wings are held out from the body, revealing a bright yellow rump patch. A foraging individual rarely stops on a perch for more than a second or two, twitching constantly and fanning the tail. Prey-hunting often begins with an explosive flight at a leaf, knocking an insect off it, this being followed by rapid aerial chases through the open understorey.

With exceptionally long rictal bristles that extend even beyond the tip of its short, broad bill, the Ruddy-tailed Flycatcher (*Terenotriccus erythrurus*) is, in many respects, a miniature *Myiobius*. The syringeal anatomy of *Terenotriccus* is so similar to that of *Myiobius* that Lanyon proposed merging the former into the latter. Such a treatment, however, would disrupt the oth-

*Although the diversity of tyrannids in scrubland and low woodland is lower than in rainforest, a significant proportion of species live in dry or open habitats. The **Bran-coloured Flycatcher** is one example. This widespread form occurs in forest edge, deciduous woodland, degraded habitats and grassland with scattered trees. Southern races migrate to Amazonian riversides during the non-breeding season. Along with the Olive-chested Flycatcher* (Myiophobus cryptoxanthus), *habitat preferences in this species differ from other members of the genus, which are humid-forest birds. Differing also in vocal characters, these two species might merit a separate genus.*

[*Myiophobus fasciatus flammiceps*, El Palmar National Park, Entre Ríos, Argentina. Photo: Julián M. Alonso]

erwise distinctive and cohesive nature of the *Myiobius* genus, as *Terenotriccus* is diminutive, lacks the concealed crown patch, and forages by perching upright with long, deliberate pauses before flush-chasing, sallying or moving. Recently, it has been shown that another diminutive species, long considered to belong in the family Pipridae, is in fact a tyrant-flycatcher closely related to *Terenotriccus*. This is the Cinnamon Tyrant (*Neopipo cinnamomea*), formerly called the "Cinnamon Manakin". Besides having almost identical plumage patterns, both the Ruddy-tailed Flycatcher and the Cinnamon Tyrant also exhibit syndactyly, having the outer two toes fused. This character is rare in tyrannids, although versions of it are common among manakins.

Although the Ornate Flycatcher was discussed above, it bears mention again here. While some features of its internal anatomy suggest an alliance with the *Phylloscartes* assemblage in the subfamily Elaeniinae, in which it is currently placed, others suggest that it belongs in the Fluvicolinae, allied with *Myiobius*, *Terenotriccus*, *Neopipo* and *Myiophobus*. Indeed, its upright posture and active, flush-chase sallies in the forest understorey would appear to make *Myiotriccus* far more "at home" as a member of this group.

Analyses of a number of internal and external morphological characters indicate that the genus *Myiophobus* is probably a sister-group to the foregoing assemblage and the following two genera, *Pyrrhomyias* and *Hirundinea*. It now seems highly likely that this genus is polyphyletic, as virtually every taxonomist who has studied it has puzzled over one or more of the species. Four of these, the Roraiman (*Myiophobus roraimae*), Orange-crested (*Myiophobus phoenicomitra*), Ochraceous-breasted (*Myiophobus ochraceiventris*) and Orange-banded Flycatchers (*Myiophobus lintoni*), may need to be removed to their own genus, as their skulls do not show the typical fluvicoline architecture.

All *Myiophobus* are small, upright-perching flycatchers of humid forest, seven of the nine species being confined to the subtropical zone of the Andes or to isolated tepuis of southern Venezuela. Only three have a continuous range of more than about 650 km. Wide disjunctions in distribution characterize several of the species. The Roraiman Flycatcher, for example, is known from southern Venezuela, two mountains in central Peru and a small region in south-eastern Peru, and two sites in the Andes of Bolivia. Altitudinal segregation is sharply defined among members of this genus, such that as many as four species may occur on the same mountain slope but with no two of them occupying the same elevational zone. The narrowness of some of these altitudinal zones probably explains why some of the species became extinct in certain areas, and why most of them are rare in collections. Their known distributions will no doubt continue to expand as the eastern Andean slopes are explored more fully. So far as their true relationships are concerned, DNA-sequencing will be necessary before it can be determined with any degree of confidence whether one, two or even three different genera are involved in this group.

In sharp contrast to the locally occurring, ecologically narrow subtropical species in this genus, the Bran-coloured Flycatcher (*Myiophobus fasciatus*) is a common, relatively easily observed species in the underbrush of tropical woodland and second growth from Costa Rica south to Argentina. Curiously, however, its apparently closely related allospecies the Olive-chested Flycatcher (*Myiophobus cryptoxanthus*) is very poorly known, and is restricted to the foothills of southern Ecuador and northern Peru. Both species are typical *Empidonax*-like tyrannids, foraging with aerial hawking and sally-gleaning within dense vegetation, especially near openings and edges. They may belong in a separate genus of their own.

The Cinnamon Flycatcher (*Pyrrhomyias cinnamomeus*) and the peculiar Cliff Flycatcher (*Hirundinea ferruginea*) appear to be closely related, and may form a monophyletic assemblage with the aforementioned *Myiobius*, *Terenotriccus* and *Neopipo*. *Pyrrhomyias* has more or less typical tyrannid proportions and upright-perching habits, although, in accordance with its obligate aerial hawking behaviour, its wings are longer than normal and its tarsi shorter. This species has a classic subtropical distribution, occurring at elevations of 1000-2500 m on the steep, moist Andean slopes in a band almost 6000 km long and only a few kilometres wide, from coastal Venezuela south to northern Argentina. It forages at forest openings, at small outcroppings, and along the edges of waterfalls.

Pyrrhomyias shares with *Hirundinea* a unique combination of syringeal and cranial characters, as well as an overall rufous plumage, including unusual patches of rufous on the wings, and an oddly "pinched" tip of an otherwise rather wide bill. The two species' distinctive calls are reminiscent of each other, although that of the Cliff Flycatcher carries much farther. Both build cup-shaped nests on cliff ledges. The Cliff Flycatcher's extremely

*One of the most ecologically specialized tyrannids, the **Sulphury Flycatcher** is seen here on its favourite kind of perch, the frond of a moriche* (Mauritia) *palm. This distinctive plant occurs in low-lying Amazonian sites, and the flycatcher is rarely seen away from large stands of this palm. When it does occur elsewhere, it is usually found in swampy areas which have palms dotted about among scattered trees. In general, this is a scarce and localized species, probably because of its specialized habitat preferences.*

[*Tyrannopsis sulphurea*, Roraima, Brazil. Photo: Arthur Grosset]

The most abundant and widespread species of Anairetes *is the* ***Tufted Tit-tyrant****. Like most of its close relatives it is an open-country bird, most frequently found amidst low shrubs on semi-arid Andean hillsides, or on the plains of Patagonia. The genus as a whole contains eight species, . most of which are known for their tit-like hyperactive perkiness and their prominent crests. Few other small flycatchers occur at such high altitudes or latitudes.*

[*Anairetes parulus*, Neuquén, Argentina. Photo: Darío Podestá]

unusual proportions, with tiny, short tarsi and long, pointed wings like those of a swallow (Hirundinidae), make sense in light of its unparalleled specialization on aerial hawking from perches on cliff faces. It is easy to imagine such a specialized species evolving from a more typical, *Pyrrhomyias*-like ancestor that hawked insects from the cliffs of an emerging Andean mountain chain.

Although currently positioned next to *Sayornis* at the end of the tribe Contopini, *Mitrephanes* appears in fact to be a perfect transitional genus connecting the two distinctive montane species just mentioned and the widespread radiation of pewees (*Contopus*). For hours on end, and day after day, the little buffy-olive Tufted Flycatcher (*Mitrephanes phaeocercus*) sits on leafless perches above the humid forest canopy, sallying into the open air near moist vegetation and returning to the same perch. Anatomically and morphologically, as well as behaviourally, the two *Mitrephanes* species are miniature pewees. They have a remarkable dawn song (see Voice).

Only four major evolutionary radiations of tyrant-flycatchers have occurred in North and Middle America, these being *Contopus*, *Empidonax* and relatives, *Tyrannus* and *Myiarchus*. The *Contopus* pewees include seven species that breed from Costa Rica northwards, four that are exclusively West Indian, and only four in South America, with one doubling up in the first and third groups. This is a well-defined genus of medium-sized to large flycatchers with distinctive, whistled songs, a disproportionately long and wide bill, well-developed rictal bristles, long wings, and short, rather slender tarsi. All have highly stereotyped foraging behaviour, sitting for long periods on conspicuous perches in the open, the head moving rapidly from side to side, and launching into acrobatic aerial hawking manoeuvres after flying prey. The largest species in the genus is the Olive-sided Flycatcher (*Contopus cooperi*), formerly known as *Nuttallornis borealis*, which breeds in Canadian spruce (*Picea*) bogs and in high montane forests of spruce and fir (*Abies*, *Pseudotsuga*) in western North America. The Eastern (*Contopus virens*) and Western Wood-pewees (*Contopus sordidulus*) and the Greater Pewee (*Contopus pertinax*) complete the geographical division of North America, so that almost any patch of forested habitat has one, and only one, pewee species breeding in it.

A large assemblage of *Empidonax*-like genera forming what seems to be a clear, monophyletic clade includes an array of North American species in *Empidonax*, four Middle American flycatchers in the genera *Aphanotriccus* and *Xenotriccus*, and three wide-ranging South American forms in *Lathrotriccus* and *Cnemotriccus*. All are small to medium-sized, large-headed, upright-perching species with a broad bill, and all forage mainly by a mixture of aerial hawking and sally-gleaning within rather open vegetation, such as the lower levels in scrub, open woodland and river-edge forest.

On the basis of both cranial and biochemical evidence, the genus *Lathrotriccus* was erected relatively recently, by the Lanyon father-and-son team, as a means of distinguishing two South American species from the other *Empidonax* relatives. One of these, Euler's Flycatcher (*Lathrotriccus euleri*), is widespread in scrubby lowland forest and dense second growth, whereas the other, the Grey-breasted Flycatcher (*Lathrotriccus griseipectus*), is restricted to western Ecuador and northern Peru, where it occupies semi-arid forests. The widespread Fuscous Flycatcher (*Cnemotriccus fuscatus*) is a large-billed relative, replacing Euler's Flycatcher in tropical scrub and open-forest habitats.

Aphanotriccus and *Xenotriccus* are represented by four species with highly restricted ranges. None is well studied, but all look and act very much like large *Empidonax* species. The two members of *Xenotriccus* are restricted to arid brush in the highlands of southern Mexico; one of them, the Pileated Flycatcher (*Xenotriccus mexicanus*), sports a bushy crest, a feature unique within the *Empidonax*-like assemblage. *Aphanotriccus* contains two even more localized forms, one found in Nicaragua and Costa Rica and the other in Panama and northern Colombia.

The discovery that the two South American tyrannids once classified in the genus *Empidonax* did, in fact, merit a genus of their own, *Lathrotriccus*, included the hypothesis that they are closest to *Cnemotriccus* and *Aphanotriccus*. This finding clarified the evolutionary history of the large genus *Empidonax*, which is now seen as a strictly North and Middle American group. *Empidonax* represents another of the notorious flycatcher complexes of extremely similar-looking species that have befuddled birdwatchers and taxonomists alike for more than a century. Ten species are primarily or exclusively North American breeders and five are mainly Middle American, but not a single species breeds south of Costa Rica. These numbers change considerably during the non-breeding season, when all of the North American species migrate to tropical habitats (see Movements).

Once grouped with the other bush-tyrants (Myiotheretes), *the* ***Red-rumped Bush-tyrant*** *has a very distinctive plumage pattern and a smaller, finer bill. These, along with several other anatomical features, explain its placement in its own genus,* Cnemarchus. *Like other bush-tyrants, it is usually found perching boldly on top of shrubs, rocks and stunted trees at high altitudes. It probably ventures higher than any other non-terrestrial tyrannids because of its association with the highest of Andean trees,* Polylepis. *It is not restricted to this habitat, however, and often forages on other types of stunted vegetation, as well as in adjacent* puna *and* páramo. *With a strikingly white crown, a white patch on its tertials, and a bright rusty belly and tail, it is one of the most beautiful of tyrant-flycatchers. This species occurs at very low densities, and can be difficult to find, even in the ideal elevational zone.*

[*Cnemarchus erythropygius erythropygius,* Peru. Photo: Günter Ziesler]

Species differentiation in *Empidonax* has occurred almost exclusively through the development of vocal and behavioural isolating mechanisms, with almost no significant changes in structure or plumage pattern. The North American Willow (*Empidonax traillii*) and Alder Flycatchers (*Empidonax alnorum*) represent one of the most classic cases, in which long-confused sibling species were finally sorted out through careful study of their distinctive songs across their full geographical ranges. R. C. Stein showed that, of two well-known song types, individual birds sing only one, either "fitz-bew" or "fee-bee-o", and that those singing one type rarely respond to songs of the other type. He also found habitat, nesting and distributional differences between birds of known song type, despite noting only slight, statistical plumage differences that could be discerned between large series of each species. A more recent, similar example is the splitting of the "Western Flycatcher" into two species, the Cordilleran Flycatcher (*Empidonax occidentalis*) and the Pacific-slope Flycatcher (*Empidonax difficilis*), following a comprehensive study by N. K. Johnson of geographical variation in morphology, vocal behaviour, ecology and genetics of the two forms. The two species can be distinguished mainly by the primary advertising song, but they also occupy quite different habitats on each side of the Cascade and Sierra Nevada mountain ranges inland from North America's Pacific coast. The story is still unfolding, as many experts familiar with these tyrannids across their ranges suspect that the subspecies *insularis* of the Pacific-slope Flycatcher, confined to the Channel Islands, off south-west California, may itself warrant recognition as a full species.

Most *Empidonax* species are widespread, occupying major biomes of North or Middle America, but a few are more restricted in distribution. The Grey Flycatcher (*Empidonax wrightii*), for example, breeds only in the arid scrublands and deserts of the Great Basin, in extreme south-west Canada and the western USA. The Buff-breasted (*Empidonax fulvifrons*) and Pine Flycatchers (*Empidonax affinis*) breed locally in relatively narrow zones of montane pine-oak (*Pinus-Quercus*) woodland from the USA-Mexico border south to southern Guatemala, the Buff-breasted Flycatcher also having an isolated population in Honduras. Taxonomic limits within the Pine Flycatcher could possibly require some revision, as vocal differences between populations on each side of the Isthmus of Tehuantepec, in Mexico, suggest that more than one form is involved; the implications of these, however, have yet to be assessed. The most localized species in this genus is the Black-capped Flycatcher (*Empidonax atriceps*), resident only in the cloudforests of Costa Rica and western Panama.

All three phoebes (*Sayornis*) are North American breeders, but the Black Phoebe (*Sayornis nigricans*) has a continuous breeding range approaching 10,000 km in length, stretching from California southwards through the Andes to Tucumán, in northern Argentina. Morphologically, *Sayornis* clusters only loosely with the rest of the *Empidonax*-like tyrants of the tribe Contopini, and along with *Pyrocephalus* represents a transitional genus between them and the large assemblage of ground and near-ground specialists in the tribe Fluvicolini.

The Vermilion Flycatcher (*Pyrocephalus rubinus*) is the most brightly coloured member of the entire family. This striking species also has an enormous range, stretching from the south-western USA through most of Middle America and southwards to northern Patagonia. It does not breed in heavily forested areas, as, for instance, in Costa Rica and Panama, and in the Amazon Basin, but it does appear as a non-breeding migrant across large areas of Amazonia. The male has a brilliant, vermilion-red crown and underparts, except in the vicinity of Lima, in Peru, where one of two local colour morphs is a solid sooty brown, with no trace of red. The species is similar to the phoebes in behaviour, generally foraging in open areas, especially near water, and frequently sallying to the ground. This is one of only two tyrant-flycatchers to have reached the Galapagos Islands, where the two subspecies present are orange-red, rather than bright red.

The remainder of Fluvicolinae consists of a large cluster of relatively closely related genera with remarkably diverse body forms and foraging habits. These are the ground-tyrants, shrike-tyrants, chat-tyrants, black-tyrants and their relatives, an assemblage that may be referred to broadly as the "ground-tyrant radiation". This group of 23 genera includes many of the most peculiar plumage adaptations and body forms in the Tyrannidae. The vast majority of these species are associated with open country, from arid scrub and open woodland to unbroken grassland and even barren terrain. Occupation of open, non-forested habitats goes hand-in-hand with ground-related foraging in several genera, and explains features of their speciation patterns as well

In common with most other members of its genus, the ***Black-billed Shrike-tyrant*** *is a solitary bird that lives in open, stony country. Some shrike-tyrants inhabit the windswept plains of Patagonia, but most live on the slopes of the high Andes. This species, the commonest and best known of the group, often perches on stone walls and low roofs in tiny settlements. It prefers to forage from a high vantage point. Some* Agriornis *species thrive in some of the driest parts of the central Andes, where vegetation is very sparse. The Patagonian race,* maritimus, *seen here, has an almost black iris. In this species, iris colour lightens progressively towards the north, and through most of the northern Andes it is white.*

[*Agriornis montanus maritimus*, Laguna Blanca National Park, Neuquén, Argentina. Photo: Julián M. Alonso]

as in their behaviour and morphology. For example, the lineage as a whole is weighted towards species with southern South American distributions. Of the 71 species and 23 genera represented, only 15 species, in eight genera, occur in Venezuela, whereas 17 genera and 43 species are found in Bolivia, and 18 genera and 44 species in Argentina.

Several authors have hypothesized a plausible scenario by which ecological, behavioural and morphological radiation occurred within the ancestry of these open-country tyrants. An apparent evolutionary track exists within the group, from generalized, arboreal foliage-gleaners in coastal or temperate scrubland and elfin forest, as typified by the chat-tyrants in the genus *Ochthoeca*, through intermediate forms occupying more wide-open country but still perching in shrubbery, such as the *Myiotheretes* bush-tyrants, the *Xolmis* monjitas and the *Knipolegus* black-tyrants, to purely terrestrial birds of steppe and barren ground, of which the *Muscisaxicola* ground-tyrants and the field-tyrant *Muscigralla* are examples. This evolutionary pathway is closely linked with gradually increasing morphological and behavioural specializations, the transitional, intermediate steps of which are remarkably well "preserved" among modern-day species. While this evolutionary scenario remains conjectural, a recent phylogenetic analysis by J. Birdsley, using anatomical, behavioural and plumage characters, does in fact corroborate the overall hypothesis reasonably well; it should, however, be noted that, in Birdsley's analysis, the *Empidonax*-like flycatchers fall within the shrub-foraging, basal clades of this assemblage, and not outside it as in the currently accepted sequence. Although a number of anatomical characters serve to unite the group as a whole and to clarify a few relationships among genera, many other relationships still remain ambiguous. It is worth mentioning that as many as 14 of the 23 genera are monotypic, and the precise order in which they are at present listed will almost certainly change as new evidence emerges. A DNA-sequencing analysis may shed further light on this fascinating assemblage.

Ecologically and behaviourally, the two species of negrito (*Lessonia*), long-legged, ground-foraging flycatchers of wet grassland and marshy surfaces, would seem to belong near the ground-tyrants, where they were placed for a century by numerous systematists. Birdsley's recent analysis supports this treatment. W. E. Lanyon, however, found syringeal characters suggesting that *Lessonia* is united with *Pyrocephalus*, and proposed that these two genera cluster together with two other sexually dimorphic genera, *Knipolegus* and *Hymenops*. The remarkably long, straight hind claw of *Lessonia* is presumably an aid when perching on and sallying from wet, marshy vegetation.

The robust-bodied, long-legged Spectacled Tyrant (*Hymenops perspicillatus*) is one of the most distinctive of all tyrant-flycatchers. It is named for its large, fleshy yellow wattle surrounding the eye, a feature found in no other member of the family. The male is jet-black with large white wing patches, and has an oversized, bright yellow bill that matches the wattle in colour. Females are dull, streaky brown, cryptically coloured to match the grassy habitat in which they live. This species breeds in marshes in Uruguay, Paraguay and northern Argentina, where it forages both with aerial sallies and by running along the ground or floating vegetation. The male's white wing patches are barely visible except when the bird flies and, especially, when it engages in its spectacular aerial courtship display (see Breeding).

Of the ten distinctive black-tyrants in the genus *Knipolegus*, many are sharply sexually dimorphic, others less obviously so, and still others not at all. Most are conspicuous aerial hawkers that perch atop shrubs or small trees bordering open country. About half occur in southern Brazil and Patagonia, but two quite uncommon species, the Riverside Tyrant (*Knipolegus orenocensis*) and the Amazonian Black-tyrant (*Knipolegus poecilocercus*), have colonized much farther north, where they are restricted to shrubby riverbanks, the edges of creeks and pools, and shrubby river islands along the Orinoco and Amazon drainages. Reduction or loss of sexual dimorphism is presumably a secondary, derived condition that has occurred independently among several species in the genus. The Rufous-tailed Tyrant (*Knipolegus poecilurus*) occurs in Andean forest openings such as cliff faces and landslides, and the male, in reverting to monomorphic plumage, a primitive trait in the Tyrannidae, has converged on the cryptic, brown female pattern; the female still has somewhat brighter, more conspicuous wingbars. Interestingly, and for unknown reasons, the females of two species, the Velvety (*Knipolegus nigerrimus*) and Crested Black-tyrants (*Knipolegus lophotes*), have taken on an all-black, male-like plumage.

The chat-tyrants in the genus *Ochthoeca* represent a fascinating, exclusively Andean radiation of medium-sized, sallying

The largest member of its genus, the ***White-fronted Ground-tyrant*** *occurs in a relatively small range in Peru, Bolivia and Chile. Within this region it appears to be virtually restricted to cushion bogs, where ice-melt trickles across level ground between humps of tough short-stemmed grass. Fortunately, while this habitat specialization might seem unusually narrow, cushion bogs are a frequent feature of the high-Andean zone. Most other ground-tyrants are adapted to dry, grassy plains, or patches of turf on rocky slopes. Many are birds of exceptionally high altitudes, though one species has colonized low-elevation sandy beaches in the Amazon Basin.*

[*Muscisaxicola albifrons*, Chivas, Peru. Photo: Marc Guyt/AGAMI]

Many tyrant-flycatchers reach their highest population density at the margin of rivers and wetlands, and the ***Torrent Tyrannulet*** *is especially closely associated with the edges of fast-rushing streams. This species spends much of its life perched on boulders, boughs, pebbly beaches, or muddy banks within a metre or two of montane or foothill waterways. In the same genus, the Sooty Tyrannulet* (Serpophaga nigrescens) *and the River Tyrannulet* (S. hypoleuca) *are waterside birds in other parts of South America. They all forage by flitting out to catch insects in flight, and by snatching them off nearby vegetation, rock faces, or the water surface itself.*

[*Serpophaga cinerea grisea*, Tapantí National Park, Cartago, Costa Rica. Photo: Marco Saborío]

tyrannids. Several distinct species groups are involved, one of which has been proposed as constituting its own genus, *Silvicultrix*. The largest and most "chat-like" of the chat-tyrants are distributed through the misty, treeless *páramo* and *puna* zones, where they include the Brown-backed Chat-tyrant (*Ochthoeca fumicolor*), and the arid western ridges, where the White-browed Chat-tyrant (*Ochthoeca leucophrys*) is a representative. Slightly lower in elevation, in the brushy elfin forest at and just below the tree-line, the four members of the "*Silvicultrix* group" are found. These are either dark sooty, as typified by the Crowned Chat-tyrant (*Ochthoeca frontalis*), or dark olive, as is the Yellow-bellied Chat-tyrant (*Ochthoeca diadema*), and all have sharply contrasting, even colourful loral spots. Farther down the slopes live the remaining two species, one of which, the Slaty-backed Chat-tyrant (*Ochthoeca cinnamomeiventris*), is often found perched at the edge of dark, moss-covered ravines and rocky waterfalls.

A recent DNA-sequence analysis strongly supports the monophyly of the chat-tyrants, with the species composing "*Silvicultrix*" embedded in the midst of it. The same study excludes the distinctive Tumbes Tyrant (*Tumbezia salvini*) as basal to this group, supporting its continued recognition as a monotypic genus, sister to *Ochthoeca*. With this phylogenetic position, and as a lowland taxon restricted to the arid Pacific coast of Ecuador and northern Peru, *Tumbezia* is plausibly viewed as a relict of the lowland ancestor that gave rise to the chat-tyrants during the Plio-Pleistocene uplifting of the Andes.

The Patagonian Tyrant (*Coloramphus parvirostris*) is among the few tyrant-flycatchers inhabiting the southern temperate forests of Chile and Argentina. It was briefly lumped in the genus *Ochthoeca*, but it has distinctive internal anatomy warranting its separate generic status. In addition, and unlike *Ochthoeca*, it may make seasonal movements. Certainly, it is a species that deserves further study.

Observant visitors who travel by boat anywhere in the Amazon Basin soon become familiar with the Drab Water-tyrant (*Ochthornis littoralis*), a common inhabitant of brushy river margins and debris-strewn shorelines throughout the Amazonian lowlands. During low-water seasons it nests on clay ledges immediately above the rushing waters of the river. *Ochthornis* has been lumped with *Ochthoeca* in the past, but it differs from the latter in internal characters and, as an ecologically unique species, it remains distinctive enough to warrant separate recognition.

Presumably because both the family as a whole and its component major lineages date back to ancient origins in South America, the tyrant-flycatchers are filled with monotypic genera that have no obvious close relative. The Yellow-browed Tyrant (*Satrapa icterophrys*) is a classic example. This species has been enigmatic to systematists for more than a century, and even modern studies have yielded few clues as to its relationships. An uncommon but conspicuous bird of brushy, open country south of the Amazon, and an austral migrant to the Venezuelan *llanos*, it perches high in the shrubs, where it makes aerial sallies, sally-gleans against leaves, and frequently eats fruit. The Yellow-browed Tyrant has been viewed by some as a distant relative of the *Ochthoeca* chat-tyrants. It is one of the species that is most in need of detailed DNA studies, in the hope that these will help to solve the mystery of its relationships within the fluvicoline tyrannids.

Internal anatomical characters indicate that the three *Fluvicola* water-tyrants and the White-headed Marsh-tyrant (*Arundinicola leucocephala*) form a clade. They also share a close ecological attachment to marsh and lakeside habitats, and species of both genera build a large, messy, globular nest of grass and bird feathers, with a side entrance. The sexually dimorphic marsh-tyrant perches in reeds or at the top of low shrubs and fence posts, sallying into the air or against grass stalks. The striking, bicoloured plumage pattern of the male is highly distinctive among the Tyrannidae, and curiously convergent with that of several independent lineages of marsh-dwelling New World blackbirds (Icteridae) in which the colour of the head contrasts boldly against an all-black body. The water-tyrants, on the other hand, exhibit minimal sexual plumage dimorphism and are, moreover, essentially terrestrial, perching on the ground, on rocky shorelines, or on floating vegetation and sallying actively for spiders and insects near the water surface. The Black-backed (*Fluvicola albiventer*) and Pied Water-tyrants (*Fluvicola pica*), formerly treated as conspecific, replace one another geographically on each side of the Amazon drainage and are almost identical in habits. The third member of the genus, the lovely Masked Water-tyrant (*Fluvicola nengeta*), is much longer-legged and behaves much

Two genera tightly linked with aquatic habitats are Arundinicola *and* Fluvicola. *In this case, the association is not with flowing water, but with stagnant pools, oxbow lakes and marshes. Shared features of plumage, internal anatomy and nesting behaviour strongly support a close relationship between these two genera.* Arundinicola *is a monotypic genus, and in parts of its range the* ***White-headed Marsh-tyrant*** *overlaps with all three species of* Fluvicola. *Although they may occasionally be found side by side at the margins of wetlands, they differ notably in habitat choice and feeding technique. In the Brazilian Pantanal, for example, the marsh-tyrant usually perches on taller vegetation such as reeds and small shrubs adjoining the edges of wetlands, whereas the* ***Black-backed Water-tyrant*** *typically perches on low floating vegetation, often far out onto the water surface. The marsh-tyrant is sexually dimorphic, but the water-tyrants are not.*

Below: *Fluvicola albiventer*, Miranda, Mato Grosso, Brazil.

Photos: Edson Endrigo]

One of the most delightful tyrant-flycatchers is almost entirely restricted to reedbeds. The ***Many-coloured Rush-tyrant*** *is unlike any other tyrannid in its striking pattern and gaudy coloration. It is quite common wherever reedbeds fringe the shores of high-altitude lakes in the central and southern Andes and in the lowlands of Argentina. As with many species that habitually perch on vertical stems, the tarsi are long and slender. The bill is fine and has a needle-tip, like a tiny pair of tweezers, for picking minute prey items from the reeds. Like most insectivorous birds that forage while perched, it has lost its rictal bristles. Its true taxonomic position is unclear, but it may be related to the doraditos* (Pseudocolopteryx)*, a group of similar-sized birds that also live in marshy habitats.*

[*Tachuris rubrigastra rubrigastra*,
Boca Budi, Araucanía, Chile.
Photo: Andy & Gill Swash]

While the Great Kiskadee (Pitangus sulphuratus) *is a common and widespread generalist, the* ***Lesser Kiskadee*** *is more of a specialist. Strictly tied to the margins of wetlands, it is captured here in characteristic pose, perched on the stem of a water hyacinth* (Eichhornia crassipes)*, above a floating mat of water lettuce* (Pistia stratiotes)*. It tends to avoid the banks of larger rivers, and prefers slow moving or stagnant waters, where it usually forages in pairs or small family groups and sallies to pick insects and spiders from plants or the water surface, often with a short hover.*

[*Philohydor lictor lictor*, Pantanal, Mato Grosso, Brazil. Photo: Hernán Rodríguez Goñi]

more like a ground-tyrant. This species has one of the most anomalous distribution patterns of any tyrannid, with a widespread population inhabiting open marshes of south-eastern South America and a locally distributed population west of the Andes, in the coastal zone of western Ecuador and northern Peru. Genetic and behavioural studies of the latter would be fascinating, as the subspecies concerned, *atripennis*, almost certainly merits full species status.

Alectrurus is a genus of two black-and-white tyrants ecologically confined to grassland and marshy habitats, and clearly related to the preceding two genera. As with *Arundinicola*, the two *Alectrurus* are sexually dimorphic. Females are cryptically coloured in brown and white, while the boldly patterned males are among the strangest of all the flycatchers. The extremely unusual tail modifications of the males appear to be associated with displays directed at rivals when competing for mates, such behaviour being typical of grassland and marsh-dwelling birds all over the world. Males of the Strange-tailed Tyrant (*Alectrurus risora*) also have the unique characteristic of losing the throat feathers entirely during the breeding season, revealing a patch of bare skin that becomes bright orange.

The ground-tyrant genus *Muscisaxicola* is largely a radiation of high-Andean tyrants, all strikingly convergent on Old World chats, especially wheatears (*Oenanthe*). They are entirely terrestrial, alternately running and stopping on long, slender legs as they search the ground and surrounding air for insect prey. Many of the 13 species are inhabitants of treeless countryside and barren, rocky terrain, where they live side by side with, and can even be confused with, sympatric furnariids such as the miners (*Geositta*). Three species live as far south as Tierra del Fuego, and all of the southernmost species are long-distance migrants (see Movements). One, the Little Ground-tyrant (*Muscisaxicola fluviatilis*), has invaded the Amazon Basin, where it forages along the larger muddy and sandy beaches of slow, meandering rivers and streams.

The genus *Agriornis* contains five species, including the heaviest-bodied tyrant-flycatcher, the Great Shrike-tyrant (*Agriornis lividus*). These are big, robust birds with huge, powerful legs and a shrike-like bill with a severe hook at the tip. Shrike-tyrants, which are found mainly in the high Andes, feed on large terrestrial insects and, occasionally, small birds, but they prefer to hunt from elevated perches such as the brick rooftops of rural houses. The four bush-tyrants in the similar genus *Myiotheretes*, also Andean, inhabit mainly upper cloudforest and the stunted, mossy brush near the timber-line known as elfin forest. They perch on exposed twigs or outcrops, sallying into the air, to vegetation or to the ground for insect prey. Many species of both *Agriornis* and *Myiotheretes*, because they occur in upper-elevation habitats on a variety of separate mountain massifs from Venezuela south to Argentina, exhibit considerable intraspecific variation.

Two spectacular bush-tyrants of the very high Andes are placed in monotypic genera. Both occur well above the tree-line, and are often found as high as 4500 m on dry, rocky cliff faces with scattered cacti, puya or *Polylepis* shrubs. The Rufous-webbed Bush-tyrant (*Polioxolmis rufipennis*) has in the past been placed variously in the genera *Cnemarchus*, *Myiotheretes* and *Xolmis*, but it warrants its own genus on the basis of its unique skull and syringeal characters. This species appears entirely grey when perched, but it flashes brilliant rufous patches in its wings and tail while foraging, sometimes "hang-gliding" or hovering with the tail widely spread, in the manner of a kestrel (*Falco*). The Red-rumped Bush-tyrant (*Cnemarchus erythropygius*), with a striking white crown, large white wing patch, and bright rusty tail and underparts that show brilliantly during foraging, is clearly a candidate for the title of the most beautiful tyrant-flycatcher. Like *Myiotheretes*, in which it has sometimes been included, this is a predatory perch-to-ground specialist hunter.

The monjitas (*Xolmis*) represent a remarkable southern South American radiation. Ecologically, most of these eight species are lowland replacements of the closely related, largely Andean genera *Agriornis* and *Myiotheretes*. Like their relatives, the monjitas are medium-sized to large-bodied birds of open, grassy and brushy terrain and rely heavily on perch-to-ground sallying from low shrubs, fences and utility poles. Four of the species have broadly overlapping ranges from southern Brazil to northern Argentina, and a fifth, the Black-crowned Monjita (*Xolmis coronatus*), migrates to this region from southern Argentina. In contrast to their highland counterparts, monjitas show little range fragmentation or intraspecific variation. Many are strikingly patterned with black and white, especially in the wings, the Grey Monjita (*Xolmis*

cinereus) being a typical example. The various harlequin patterns are dazzling and highly visible as the birds move from perch to perch with long overhead flights. The White Monjita (*Xolmis irupero*) is pure white, with jet-black wings. Its local name of "ghost bird" refers as much to its seeming preference for perching atop gravestones as to its ghostly plumage. The Fire-eyed Diucon (*Xolmis pyrope*), formerly placed in a monotypic genus *Pyrope*, is distinctive within the group, having an all-grey back, whitish underparts and a spectacular, brilliant red iris. Unlike its congeners, which are perch-to-ground foragers, this species is more of an aerial hawker.

Two monotypic genera of southern Brazil and adjacent countries, both having an elongated tail, are of uncertain affinities within the Fluvicolinae. The Streamer-tailed Tyrant (*Gubernetes yetapa*) is among the most spectacular of tyrannids. A very large tyrant of open country, it has a voluminous bill with which it captures very large insect prey mainly on the wing, but also in long, angled sallies to the ground, where it also seizes small vertebrates. Its exceptional tail is convergent with that of two members of the subfamily Tyranninae, the Scissor-tailed (*Tyrannus forficatus*) and Fork-tailed Flycatchers (*Tyrannus savana*), the fork clearly serving to aid aerial manoeuvring during long acrobatic sallies after flying prey. *Gubernetes* differs from all other tyrant-flycatchers in having a conspicuous white "bib" bordered below by a bright chestnut breastband; mated partners engage in elaborate duets accompanied by wing-flapping and tail-raising (see Voice, Breeding). The Shear-tailed Grey Tyrant (*Muscipipra vetula*) perches atop tall trees and sallies into the air for flying prey. It breeds high in the south-eastern Brazilian mountains, but migrates to the lowlands and becomes largely frugivorous during the austral winter. The taxonomic affinities of this peculiar, little-studied tyrannid have long been in dispute, but Lanyon succeeded in assigning it unambiguously to the Fluvicolinae on the basis of characteristics of its nasal septum and syrinx. Its relationships within the subfamily are unknown.

Completing the list of the Fluvicolinae are three monotypic genera the relationships of which are unknown. The Long-tailed Tyrant (*Colonia colonus*) is another black-and-white fluvicoline, but its distinctive internal anatomy, its cavity-nesting habits and its uniquely elongated central rectrices provide few clues as to its relationships within the subfamily. It is an obligate aerial-hawking species of lowland forest openings and clearings, returning time after time to the same perch after long sallies to snatch flying insects, among which it apparently favours bees and wasps (Hymenoptera) in particular (see Food and Feeding). This species has tiny feet, and virtually always perches high on an exposed dead or nearly leafless tree within a clearing, or on an isolated dead limb emerging from the forest edge. It is tempting to speculate that this strong preference for tall, isolated and leafless perches might explain its evolution into a cavity-nester, as this trait is otherwise absent in the Fluvicolinae.

One of the most terrestrial of all tyrannids is the bizarre little Short-tailed Field-tyrant (*Muscigralla brevicauda*), which has unusually long legs, very short, rounded wings, and an extremely short tail. Its legs are so long that the scutellation extends about 10 mm above the tarsal joint, making the legs look like those of a shorebird (Scolopacidae). The species is confined to the arid coast between south-west Ecuador and north-west Chile. In its ecology, its behaviour and its nondescript, grey plumage this species is highly reminiscent of an extreme version of the *Muscisaxicola* ground-tyrants, representing the final stage in the evolutionary pathway towards specialization on ground-foraging. Surprisingly, however, its anatomical characters are unlike those of *Muscisaxicola*, and are so ambiguous that this odd, long-legged flycatcher is currently placed at the end of the Fluvicolinae in a grab-bag of genera of uncertain affinities, all awaiting detailed genetic analysis.

The Cattle Tyrant (*Machetornis rixosa*) is a genuine taxonomic enigma. In plumage it is extremely similar to the yellow-bellied kingbirds in the genus *Tyrannus*, even sharing the same bright orange, semi-concealed crown patch so common among the large, yellow-bellied tyrannines described in the paragraphs immediately below. *Machetornis* forages in wide-open settings, where, like the kingbirds, it often perches high on treetops or utility poles. Even its courtship display is similar to that of the Tropical Kingbird (*Tyrannus melancholicus*). The Cattle Tyrant, however, also routinely rides on the backs of livestock in search of dislodged insects, and even more frequently it walks along the ground, probing and gaping for insects among grass tufts in a manner much more like that of a meadowlark (*Sturnella*) than that of any other tyrant-flycatcher. Its wings are rounded, unlike those of the kingbirds, although it does, like the latter, have pointed primaries. To date, the most important clue as to the evolutionary

All four species of Pseudocolopteryx *are associated with wetland habitats, favouring beds of reeds and sedges. Unlike some other reedbed tyrannids, however, they are inclined to venture into adjoining shrubs. The* ***Warbling Doradito*** *breeds in Chile, Argentina, Uruguay and southernmost Brazil, with some northward movement in the austral winter, when small numbers reach Paraguay and Bolivia. All doraditos are ecologically and morphologically similar, and it is very rare for more than one species to breed at any given site.*

[*Pseudocolopteryx flaviventris.*
Photo: Yves Bilat/Ardea]

Some of the larger tyrant-flycatchers are pugnacious birds. In most cases their aggression is directed to their own kind during fights for territories or mates. At other times it spills over into interspecific behaviour: this ***Great Kiskadee*** *is trying to oust a* ***Tropical Kingbird*** *from its perch. Many tyrannid species live in open country, where they prefer to forage from the tops of bushes.The fearless attitude of tyrant-flycatchers manifests itself most conspicuously in their anti-predator responses, and a Great Kiskadee or kingbird may attack a raptor, crow or vulture so vigorously that it ends up riding briefly on the back of its fleeing enemy. The common tendency for kingbirds to mob larger birds gave rise to their tyrannical reputation, and thus their English name.*

[*Pitangus sulphuratus maximiliani*, *Tyrannus melancholicus melancholicus*, Pantanal, Mato Grosso, Brazil. Photo: Günter Ziesler]

*This **Long-tailed Tyrant** is taking a break between aerial forays to rearrange its plumage. As in all birds, plumage maintenance is vital to tyrant-flycatchers. Because of its aerial foraging strategy, this tyrant perches with its tiny legs on high, prominent twigs, to which it regularly returns after a sally. In many places it seems to specialize on stingless bees. Its most peculiar features are a pair of elongated, blade-shaped central rectrices. The position of these feathers in the central rather than at the sides of the tail, along with their flexibility, suggests that their function is ornamental rather than aerodynamic.*

[*Colonia colonus colonus*, Iguazú National Park, Misiones, Argentina. Photo: Julián M. Alonso]

position of the mysterious *Machetornis* within the Tyrannidae is that its skull appears to be typically fluvicoline, hence its inclusion at the end of this subfamily.

The third subfamily, Tyranninae, is considerably more uniform morphologically than is either of the preceding two. A variety of analyses of this subfamily provide evidence for its monophyly within the Tyrannidae. In particular, a recent comprehensive analysis of the cytochrome *b* and ND2 mitochondrial-gene sequences, carried out by J. Mobley, corroborates the earlier conclusions of monophyly by Lanyon, whose findings were based mainly on cranial morphology, and McKittrick, whose work focused on forelimb musculature.

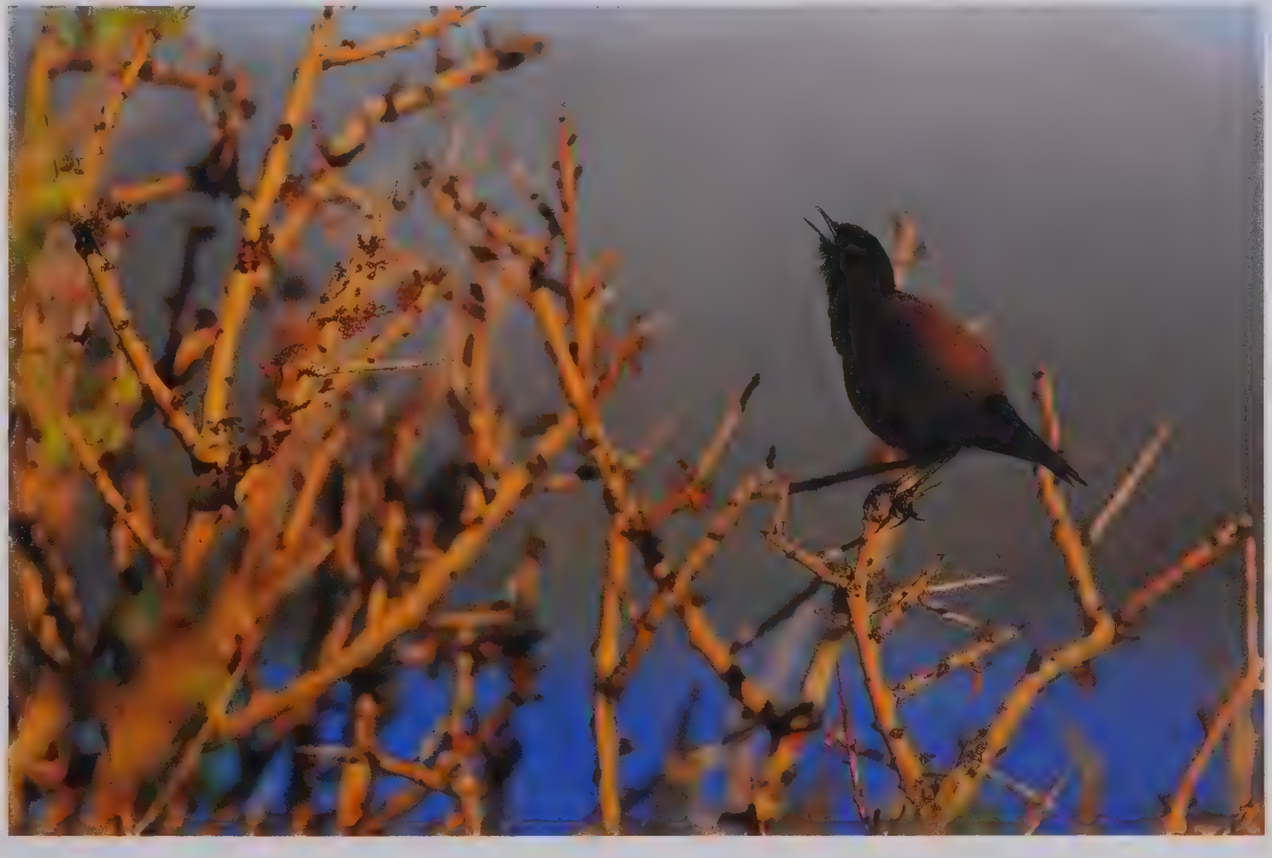
Tyranninae contains 75 medium-sized to large flycatchers currently divided into 20 genera, eight of which are monotypic. All members of this subfamily are comparatively large-headed but, with the exception of two *Tyrannus* species possessing greatly elongated "scissor" tails, they otherwise have typical tyrannid proportions. The subfamily includes the only successful radiation of open-country flycatchers within North America, the genus *Tyrannus*. It also contains a disproportionately large number of successful species with extensive geographical ranges. Some of these extend from the USA or northern Mexico southwards all the way to central or southern South America. The ecological success of this subfamily is probably a consequence of the tendency among this group to favour well-lit, open habitats and forest edge. In effect, the Tyranninae are distributed along the edges and even "over the top" of most tropical vegetation types, from desert to rainforest. Many of the species are sympatric over large areas, and a good lakeshore or brushy pasture in the tropics can easily harbour up to ten large resident tyrannine flycatchers, most of them among the noisiest and most conspicuous birds in the area. Only a few species live in the deep interior of tropical forest. Presumably as a result of the preference for open country and the migratory habits of many of its species, Tyranninae has successfully colonized the West Indies and produced an endemic radiation there.

Two quite different, evidently monophyletic lineages, each containing a major North American component, make up the Tyranninae. One group consists of the kingbirds (*Tyrannus*) and their allies, including a remarkable array of species and genera that exhibit variations on an unusual colour pattern of bright yellow belly, olive or brownish back, and a bold head pattern of grey or black and white stripes. The other lineage contains the large, widespread genus *Myiarchus* and a collection of smaller, strictly tropical genera, the taxonomic affinities of which were clarified relatively recently. These two groups are herein separated as the tribes Tyrannini and Attilini, respectively.

The kingbirds and their allies are conspicuous, large-bodied, comparatively large-headed tyrannids with a robust bill. Genetic

*In forests, most tyrant-flycatchers are notably absent from the afternoon assembly of understorey birds bathing at streamsides and puddles. They seem to avoid these static bathing sites, preferring instead to make use of the occasional downpour. Heavy rain will often send them to a prominent perch, where they shake out their feathers and ruffle their wings in wet foliage, as demonstrated by this **Rusty-margined Flycatcher**.*

[*Myiozetetes cayanensis cayanensis*, Le Larivot, Matoury, French Guiana. Photo: Olivier Tostain]



and anatomical studies strongly indicate that the group is monophyletic, and for the most part even the generic and supergeneric affinities are now reasonably clear. All species have a semi-concealed yellow, orange or red crown patch that is revealed as the ample crown feathers are raised during active courtship or aggressive display (see Breeding). Wingbars are absent almost throughout, and several distinctive plumage patterns found only in this assemblage recur across the group. The most frequent of these is typified by the Great Kiskadee (*Pitangus sulphuratus*), which has bright yellow underparts, black and white head stripes, and dull olive to brownish upperparts. This pattern appears also in the genera *Myiozetetes*, *Phelpsia*, *Philohydor*, *Conopias*, *Megarynchus* and, in part, *Myiodynastes*. In a common variant of this pattern, the crown and head are more uniformly grey, sometimes with a whitish eyestripe; this occurs in *Myiozetetes*, *Conopias*, *Tyrannopsis* and *Tyrannus*. A third recurring plumage pattern, found in *Legatus*, *Myiodynastes* and *Empidonomus*, is that of bold stripes of brown and white both below and above, with varying amounts of rufous in the wings, rump and tail.

The Piratic Flycatcher (*Legatus leucophaius*) is an unusual species. It is highly frugivorous throughout the year, and spends much of its time sitting high above cacique and oropendola (Icteridae) colonies, calling incessantly, and occasionally flying off to a fruiting tree to fill up on ripe fruit before returning to its watchpost. Its association with cacique colonies is related to its habit of forcibly appropriating the nests of the larger icterids (see Breeding). The Piratic Flycatcher is highly migratory, moving from both ends of its range into the equatorial latitudes in response to changing availability of fruit within these regions. Several biologists have speculated that individuals of this species may breed at both ends of their migratory routes, but this remains to be confirmed (see Movements).

In open-country settings of the tropics from Middle America southwards to Bolivia and Argentina, species of the genus *Myiozetetes* are among the most conspicuous of tyrant-flycatchers, often living just outside the front doors of human dwellings. Anatomical and DNA studies strongly indicate that this group of four species is monophyletic, and in some parts of the Amazon Basin three of the four may be found together. This is a fruit-eating genus, and all of its members are frequently encountered in the company of parrots (Psittacidae), doves (Columbidae), toucans (Ramphastidae) and tanagers at large fruiting trees, such as figs (*Ficus*) and members of the families Lauraceae and Anonaceae, along the edges of forest or exposed in man-made clearings. By far the most conspicuous and widespread is the Social Flycatcher (*Myiozetetes similis*), one of the first birds encountered in any visit to tropical South America. Despite its English name, this species does not live in social groups but, rather, as endlessly chattering territorial pairs, often nesting in close proximity to one another, with frequent arguments taking place. The rarest and most enigmatic in the genus is the Dusky-chested Flycatcher (*Myiozetetes luteiventris*), much smaller than the others, lacking the conspicuous white supercilium so common throughout this assemblage of genera, and with a much tinier bill and small feet. It is very poorly known, with a spotty distribution across the Amazonian lowlands. At various times it has been switched to the genus *Tyrannopsis*, but recent discoveries of its bulky, grassy nest and its typical *Myiozetetes* syrinx have confirmed its place in this genus.

The nest of the White-bearded Flycatcher (*Phelpsia inornata*) is so distinctive within the kingbird assemblage that, along with an unusual syringeal morphology, it served as a diagnostic generic character. The nest closely resembles those built by the pewees in the genus *Contopus*, a large, neat cup covered with lichens and bound together by cobwebs, and saddled on a horizontal branch. This species was previously placed in the genus *Conopias*, which it resembles physically, but the latter nests in cavities and has quite a different syringeal structure.

No tyrant-flycatcher matches the Great Kiskadee in foraging versatility. This, the sole member of the genus *Pitangus*, is the supreme ecological generalist of the family, and in its behaviour and morphology, with robust body proportions, a large and slightly hooked bill and strong legs and feet, the kiskadee exhibits convergences with the New World jays. Even its loud voice, the most raucous and carrying of any species in the family, bears some resemblance to that of the jays. For a long time believed to be closely related to this species, and formerly treated as congeneric, the Lesser Kiskadee (*Philohydor lictor*) is, by comparison, a much more retiring bird, found almost exclusively low down along the grassy and brushy margins of slowly moving or still water, such as marshes, ponds and oxbow lakes. The sy-

Probably because of the simplicity of their syrinx structure, most tyrannids have very simple songs. This situation is taken to its extreme in the terrestrial, open-country tyrannids, many of which are barely vocal at all. The ***Austral Negrito****, for example, hardly ever utters a sound. It is known to produce quiet alarm notes and a high-pitched twitter on rare occasions, but no true song is known. The negritos are a pair of medium-sized terrestrial species that are distantly related to the ground-tyrants, but probably closer to the sexually dimorphic genera* Pyrocephalus, Knipolegus *and* Hymenops.

[*Lessonia rufa*, Laguna Blanca National Park, Neuquén, Argentina. Photo: Julián M. Alonso]

*The **Southern Beardless Tyrannulet** is a tiny, entirely drab bird. It is widespread and generally common in the forest borders, drier woodland and open shrubland of tropical South America. As with many other small tyrannids, awareness of its distinctive vocalizations reveals that this species is quite common in many areas. Also typical of many tyrannid species, geographical variation exists in its voice, perhaps indicating that more than one species is involved.*

[*Camptostoma obsoletum obsoletum*, El Palmar National Park, Entre Ríos, Argentina. Photo: Julián M. Alonso]

ringes of the two kiskadees have internal cartilages that are utterly dissimilar, and their voices are quite unlike one another, the most common call of the Lesser Kiskadee being a soft, guttural mew. Their nests also differ: that of the Great Kiskadee is a large, bulky ball with a side entrance, whereas the Lesser Kiskadee builds a saucer-shaped cup of twigs and vine tendrils. These dissimilarities led Lanyon to propose the new genus *Philohydor* for the smaller species. The DNA analyses by Mobley supported the contention that the affinities of *lictor* lie well away from *sulphuratus* within the Tyranninae, thus making recognition of *Philohydor* mandatory, despite the striking physical similarities between these two species.

Only two genera closely allied to the kingbirds nest in holes, but whether this behaviour reflects common ancestry or, as Mobley's DNA-sequence data suggest, arose independently remains unknown. *Conopias* contains four small, generalist flycatchers that resemble *Myiozetetes* physically, but generally occur in small openings within more forested habitats. *Myiodynastes* comprises five large-bodied, large-billed species that cover almost the entire range of plumage diversity found across the kingbird assemblage as a whole. Members of the latter genus forage in open forest canopy and understorey, where they snatch large insect prey from leaves, from the air and even from the ground. They also eat large quantities of fruit, especially during the non-breeding season. They have a remarkably wide ecological and latitudinal span. The Sulphur-bellied Flycatcher (*Myiodynastes luteiventris*) breeds in the cottonwood-lined river courses of Mexico north to the USA border, and the very similar Streaked Flycatcher (*Myiodynastes maculatus*) breeds across the lowlands of South America southwards to central Argentina. A third streaked species in this group, Baird's Flycatcher (*Myiodynastes bairdii*), is confined to the arid Pacific lowlands. The remaining two species are much yellower, with less body streaking but retaining the bold head stripes, thereby representing a transition to the kiskadee plumage pattern. The Golden-crowned Flycatcher (*Myiodynastes chrysocephalus*) occupies cloudforest at lower and middle elevations in the eastern Andes, and is replaced in Panama and Costa Rica by the Golden-bellied Flycatcher (*Myiodynastes hemichrysus*).

The Boat-billed Flycatcher (*Megarynchus pitangua*) has the distinction of possessing the largest bill of any tyrannid. Extremely similar to the kiskadees in plumage and body form, this species is widespread throughout tropical forest and forest edges. It lives high in trees, and snatches very large prey, from moths to arboreal snakes and lizards, from the undersides of leaves.

The relatively poorly known Sulphury Flycatcher (*Tyrannopsis sulphurea*), an inhabitant of the Amazon and southern forests, is almost certainly a kingbird ally, and its inclusion within *Tyrannus* has been proposed by some authors. This species, however, differs in many respects, both internally and externally, from the typical kingbirds. It has a very short, squared tail, a relatively short and broad bill, and unusually short legs. Its syringeal structure vaguely suggests a relationship with *Megarynchus*, but it clearly deserves its own genus. This interesting species, much in need of further study, appears to occur mainly in *Mauritia* palm stands, although it is possibly nomadic.

Two peculiar, highly migratory South American species constitute the genera *Empidonomus* and *Griseotyrannus*. These are kingbird-like in aspect and behaviour, being medium-sized, treetop flycatchers that sally for aerial prey and also regularly eat fruit. The Variegated Flycatcher (*Empidonomus varius*) is easily mistaken for the smaller Piratic Flycatcher or the larger Streaked Flycatcher, but is recognized by its bright rusty rump and tail. It migrates from the open country of southern Brazil and Argentina northwards to the *llanos* of Venezuela. The Crowned Slaty Flycatcher (*Griseotyrannus aurantioatrocristatus*), with the longest scientific name of any bird species, has an unusual syrinx and very distinctive slate-grey plumage with a black crown and fiery gold concealed crown patch. Despite the remarkable differences between the two, however, both Lanyon's anatomical analysis and Mobley's DNA-sequence data indicate that the early taxonomists were correct in their assessment that they are closest relatives, and indeed they are still commonly placed together in *Empidonomus*. The DNA data are highly suggestive that this pair of species represents a basal "out-group" to the rest of the kingbird-like assemblage.

Thirteen species make up *Tyrannus*, the type genus of the family and one of the most widespread and familiar flycatcher groups in the New World. These are the kingbirds, so named for the ample crown feathers that give every member of this group a distinctively rear-crested profile. When raised in active display, these bushy crown feathers split into two flanking crests and reveal a fiery red, orange or yellow coronal patch. This genus includes two species, the Scissor-tailed and Fork-tailed Flycatchers, which for a long time were separated in their own genus, *Muscivora*, on the basis of their having an exceptionally long, forked tail. Internal, behavioural and genetic evidence, however, prove that these two species are indeed kingbirds, and their elegant tails appear, moreover, to be independently evolved from two different origins within the genus.

All kingbirds are aerial-hawking specialists inhabiting open country and woodland or forest edges, where they sit on exposed perches, often high overhead, on the lookout for flying insects. They have long pointed wings and a forked tail, both features facilitating powerful aerial sallies and agile flying manoeuvres in pursuit of prey. Many species are highly migratory (see Movements).

Members of the genus *Tyrannus* occur from northern Canada south to southern Argentina and throughout the West Indies, making this the most widespread genus of tyrant-flycatchers and one of the few tyrannid groups to have a centre of radiation in western North America. Eight species breed at least marginally within the USA, although four of these do so just at the northern edges of large tropical distributions. Two are restricted to the West Indies, and one of these, the Giant Kingbird (*Tyrannus cubensis*) of Cuba, has by far the largest bill within this genus of large-billed birds. The Grey Kingbird (*Tyrannus dominicensis*) breeds throughout the Caribbean, including the mainland margins from Florida and Mexico around to Venezuela, and frequently is one of a small handful of bird species inhabiting the tiniest islands of the Bahamas or the Antilles. Only two kingbird species are restricted to South America. These are the Snowy-throated Kingbird (*Tyrannus niveigularis*) of the Pacific lowlands and the White-throated Kingbird (*Tyrannus albogularis*), patchily distributed in grassland from Venezuela to south Brazil.

*The **Grey Monjita** is a bird of scattered tall trees in the* cerrado *and* pampas *of Brazil, Bolivia, Paraguay, Uruguay and Argentina. It is a conspicuous bird, usually perching on the uppermost branches of trees, and often is the largest passerine in the sparsely vegetated habitats of its range. As with its congeners, its voice is entirely unremarkable. It spends the vast majority of its time silent, but during the breeding season it will break into a simple whistled rendition of "peeee, preeu", sounding unexpectedly quiet given the size of the bird. As it sallies into the air or to the ground in pursuit of insects, or passes from perch to perch with strong wingbeats, intermittent glides and dangling legs, it can resemble a small raptor. The Grey Monjita is often mobbed and harassed by smaller passerines, perhaps because it may occasionally take baby birds, as some of its relatives in the genus* Agriornis *are known to do.*

[*Xolmis cinereus pepoaza*, El Palmar National Park, Entre Ríos, Argentina. Photo: Julián M. Alonso]

The evolutionary radiation of the tyrant-flycatchers occurred through many successful modifications of a simple "search-and-sally" foraging mode. Most species are insectivores, and the various discrete foraging modes provide an ecological index by which to subdivide the family. Several genera, including Hemitriccus, *use a technique called the "upward sally-strike". This involves scanning the underside of leaves until prey is spotted, then darting upwards explosively, to snatch the item from the leaf. For this reason, species such as the* ***Pearly-vented Tody-tyrant*** *incessantly peer upwards while they forage.*

[*Hemitriccus margaritaceiventer margaritaceiventer*, El Palmar National Park, Entre Ríos, Argentina. Photo: Julián M. Alonso]

Eight further genera in the subfamily Tyranninae seem to be less close to the preceding twelve, and are grouped together in the tribe Attilini. The phylogenetic affinity between the genera *Rhytipterna*, *Sirystes* and *Casiornis* and the large genus *Myiarchus* is now overwhelmingly supported by both anatomical and behavioural evidence. Indeed, in certain respects, even the generic boundaries within this assemblage are open to question. For the greater part of the twentieth century, *Casiornis* and *Rhytipterna*, along with the genus *Attila*, were treated by taxonomists as belonging in the Cotingidae, excluded from the Tyrannidae on the basis of their tarsal scutellation. Members of both genera are forest and woodland inhabitants that perch for long periods and make bold sallies to snatch or hover-glean very large prey in the dimly lit mid-storey and subcanopy. They often follow mixed-species foraging flocks. Together with the two *Laniocera* species, discussed below, the *Rhytipterna* mourners share with the morphologically similar cotingid genus *Lipaugus* a striking pattern of plumage variation among sister-species. Each has a widespread Amazonian species and a closely related representative in Central America and western Colombia. In each case, the Amazonian form is grey-green and the Central American one is bright rufous. It is not known whether this parallel plumage variation among such ecologically and morphologically similar species is coincidental convergence or a case of mimicry among close competitors. The Pale-bellied Mourner (*Rhytipterna immunda*), although extremely poorly known, is apparently widespread in scrubby white-sand woodland within the Amazon Basin and out into the *cerrado* woodlands to the south, where it sings a peculiar dawn song resembling that of a finch (Fringillidae). This species so closely resembles members of the genus *Myiarchus*, especially the Short-crested Flycatcher (*Myiarchus ferox*), that only its serrated tarsi provide positive confirmation of its generic identity.

For a century or so, the highly distinctive black-and white Sirystes (*Sirystes sibilator*) floated as a flycatcher of unknown affinities, but the discovery of its hole-nesting habits and *Myiarchus*-like internal characters made it much clearer that it is closely related to the latter genus. Indeed, were it not for the striking uniformity otherwise characteristic of the *Myiarchus* flycatchers, argument could be made that *Sirystes* belongs inside that genus, as its only interior-forest representative. As its specific name of "*sibilator*" suggests, the Sirystes is heard far more often than it is seen. It lives almost exclusively in the highest, emergent trees of the tropical forest canopy, but its ringing call (see Voice) gives away its presence.

With 22 currently recognized species, *Myiarchus* is the largest and one of the most widespread of all tyrant-flycatcher genera. Two species, the Great Crested Flycatcher (*Myiarchus crinitus*) and the Ash-throated Flycatcher (*Myiarchus cinerascens*), breed entirely in North America. Two others have a very broad distribution, extending from the south-western USA south to Bolivia and Argentina; these are the Brown-crested (*Myiarchus tyrannulus*) and Dusky-capped Flycatchers (*Myiarchus tuberculifer*). A further six are strictly West Indian, representing the most numerous tyrannid radiation among the Caribbean islands. One species even reached the Galapagos Islands, where it became much longer-legged that its mainland congeners; ecological release appears to be causing the Galapagos Flycatcher (*Myiarchus magnirostris*) to begin converging on the ground-tyrants both morphologically and behaviourally, as this species frequently sallies to the ground for insect prey. The genus as a whole is astoundingly uniform in plumage and structure, and it required painstaking, career-long studies by W. E. Lanyon before species limits within it were adequately determined. A number of species had been "hiding" within other forms, and were revealed only through careful study of their vocalizations. For example, the locally distributed Panama Flycatcher (*Myiarchus panamensis*) and Venezuelan Flycatcher (*Myiarchus venezuelensis*) had for many decades masqueraded as races of the widespread Short-crested Flycatcher, which has a totally dissimilar vocal repertoire. All *Myiarchus* flycatchers build nests inside cavities, and line them with fragments of snake or lizard skin and with mammalian hair.

Discovery that a confusing Mexican endemic, the Flammulated Flycatcher (*Deltarhynchus flammulatus*), nests in holes helped to resolve its systematic position as another member of the *Myiarchus* assemblage. Moreover, details of its syringeal structure and its plumage pattern, characterized by diffusely streaked underparts and distinct wingbars, features otherwise absent among *Myiarchus* and its relatives, pointed to a surprising relationship with the South American genus *Ramphotrigon*. The latter had long been assumed to be related to the other flatbills in

Most tyrant-flycatchers are able to snatch flying insects on the wing, and a few groups are specialized in this foraging mode. Their agility and aerial manoeuvrability are remarkable, for they are often able to surprise the speediest of prey, such as dragonflies and dipteran flies. More commonly, however, they aim for slower-moving targets. This admirable portrait shows a ***Say's Phoebe*** *in flight with its catch. This familiar bird of the western USA has a long, triangular bill designed to trap insects in flight, an action that is often accompanied with an audible snapping of the mandibles. It is most often encountered perched on rock faces and flitting out over open spaces or down to the ground, occasionally hovering motionless in search of a prey item.*

[*Sayornis saya saya*, California, USA. Photo: Dave Maslowski/ Maslowski Productions]

the elaeniine genera *Rhynchocyclus* and *Tolmomyias*, but the cranial anatomy and hole-nesting habits of its three members reveal them as tyrannines related to *Myiarchus*. *Ramphotrigon* is restricted to Amazonia. All three of its morphologically similar species use primarily the upward-strike foraging mode, and their daytime songs are distinctive but plaintive whistles that can easily go unnoticed, although they also have strident dawn songs (see Voice). The widespread, but retiring, Rufous-tailed Flatbill (*Ramphotrigon ruficauda*) is a bird of *terra firme* forest and tall floodplain-forest, where it perches 4-10 m up in the dark, relatively open understorey and whistles its soft, undulating "whooooo-are-you". The other two species have much narrower habitat requirements. The Large-headed Flatbill (*Ramphotrigon megacephalum*) occurs mainly in dense canebrakes and bamboo thickets, often singing its plaintive "coo-koo"; although still rare in museum collections, this species is in fact rather common in its specialized habitat. The Dusky-tailed Flatbill (*Ramphotrigon fuscicauda*), similarly rare in collections, inhabits vine tangles and dense, often swampy, broken forest openings in the western Amazon Basin. Its rapidly falling whistle is accented with an abrupt, upward ending, "peeeeeew-wérp". The plaintive, whistled song of *Deltarhynchus* is reminiscent of these three, adding vocal evidence for its relationship to this group.

The final genus that falls clearly within the Tyrannidae is *Attila*, a remarkable group of seven large-bodied, tropical species formerly placed outside the family because they lack the booted tarsus of typical tyrant-flycatchers. In behaviour and general aspect, *Attila* seems to belong to the *Myiarchus*-like assem-

The most advanced terrestrial foragers are found in the fluvicoline assemblage. Foremost amongst these are the ground-tyrants in the genus Muscisaxicola. *Almost all their foraging occurs on the ground and they are behaviorally and morphologically similar to pipits* (Anthus) *or thrushes* (Turdus). *In fact, all ground-tyrants feed in roughly the same manner, and their foraging style most closely approaches that of the Old World wheatears* (Oenanthe). *They make rapid hopping runs, then suddenly stop and stand erect, often on a small rock, whereupon they may briefly shiver the tail. If they happen to see an insect within range, they pounce towards it and snatch it from the ground. The larger species are sufficiently nimble to catch a lizard on the run. An impressive radiation of* Muscisaxicola *species occurs in the barren-looking mountains of Bolivia, Chile and Argentina, and their diversity is enhanced by ecological partitioning of habitats. As seen here, the* ***Ochre-naped Ground-tyrant*** *is usually found in wet areas such as moist grassland and along the shores of high-Andean lakes, while the* ***Cinnamon-bellied Ground-tyrant*** *prefers dry grassy hillsides strewn with boulders.*

In the large genus Myiarchus, *many species, such as the* ***Great-crested Flycatcher****, prey on a wide variety of arthropods, even including stinging wasps, bees and ants (Hymenoptera). An extensive survey of this species across the USA during the breeding season revealed that its diet comprised 21% butterflies and moths (Lepidoptera), 17% beetles (Coleoptera), 16% grasshoppers, katydids and so on (Orthoptera), 14% bugs (Hemiptera) and 14% Hymenoptera.*

[*Myiarchus crinitus*, Everglades National Park, Florida, USA. Photos: Rob Curtis/ The Early Birder]

blage within the Tyranninae, and the fact that its members nest in tree cavities supports this notion. Its cranial characters, however, are ambiguous. Many species of *Attila* appear to lack the ossified nasal capsule that unites the *Myiarchus*-like assemblage, including *Deltarhynchus* and *Ramphotrigon*. Nevertheless, Birdsley recently located one specimen of the Cinnamon Attila (*Attila cinnamomeus*) that possesses this character, suggesting that it may vary individually or with age in this genus, and lending some supportive evidence for the inclusion of *Attila* in the *Myiarchus* assemblage.

Attilas are powerful birds of the middle storey of tropical forest and deciduous woodland. The long, powerful, hooked bill is convergent with that of the high-Andean shrike-tyrants and, in common with that group, the attilas often attack and subdue very large prey (see Food and Feeding). The bright yellow iris and the copious growth of stiff, protective feathers around the face add to the menacing look that is characteristic of this genus, thus explaining its scientific name. The Bright-rumped Attila (*Attila spadiceus*) is distributed from southern Mexico southwards through Amazonia, with an isolated subspecies in the Atlantic Forest of Brazil. Its ringing song, a series of sharply rising single or double notes with a final downward-slurred note, is among the most characteristic sounds of a variety of Neotropical forest and open-woodland habitats. This species is one of the very few tyrannids to occur as several distinct colour morphs, bright rufous, dark olive and olive-grey, all having a yellowish belly and a sharply contrasting yellow rump.

The systematics and evolutionary history of the genus *Laniocera* remain utterly confusing. This genus has ridden along with the other "mourners" of the superficially similar genus *Rhytipterna* in being moved back and forth between the Cotingidae and the Tyrannidae, but the recent discovery that one of its two members, the Cinereous Mourner (*Laniocera hypopyrra*), builds a messy, cup-shaped nest indicates that the genus is not a member of the *Myiarchus* assemblage. Fieldworkers familiar with its behaviour and vocalizations have long suspected that, unlike *Rhytipterna*, *Laniocera* is indeed a cotingid, perhaps close to *Laniisoma* in that family. Detailed anatomical studies by Prum and Lanyon recently revealed a number of cranial and syringeal characters supporting the membership of *Laniocera* in a hypothesized monophyletic group of primitive tyrannoids, referred to as the "*Schiffornis* group"; besides *Schiffornis*, which is currently treated in the family Pipridae, this also includes two other tyrannid genera, *Xenopsaris* and *Pachyramphus*, and the two cotingid genera *Laniisoma* and *Iodopleura*. The higher-order relationship of this group to the rest of the tyrannoids, however, remains ambiguous, and evidence from allozyme and DNA-sequence data does not even corroborate the monophyly of such a group. What does seem clear is that *Laniocera* does not belong in the family Tyrannidae. Nevertheless, in the absence of sufficient relevant information, it is retained here for the time being, even though it is recognized that this placement is almost certainly erroneous.

Placed at the end of the family sequence are three genera the systematic position of which is far from clear. For convenience, they are combined in the subfamily Tityrinae, but further research is likely to demonstrate such treatment to be inappropriate. The expanded genus *Pachyramphus*, with 17 species, contains the taxonomically confusing group known as the becards, and includes the three larger-bodied, more uniformly plumaged species formerly treated in a separate genus, *Platypsaris*. While *Pachyramphus* is a well-defined genus, the becards are odd birds, the swollen, bicoloured bill being unique in the Tyranni. Most species are sexually dimorphic, a rare phenomenon in the Tyrannidae; the black, black-and-white or grey plumage of males is replaced with brown in the females. The ninth primary of the male is highly modified, being only about half as long as those on each side of it and abruptly emarginated at its tip. All becards build a huge, bulky stick nest with a side entrance, and the nests are either suspended from an overhanging branch, as in the "*Platypsaris* group", or braced on to the fork of a horizontal limb or crotch of a tree. As mentioned in several places above, the systematic position of *Pachyramphus* appears to be basal to the rest of the family. Morphological evidence and DNA-DNA hybridization data suggest relationships with a so-called "*Schiffornis* group", but the validity of that group has been questioned by the findings of other studies, and both its composition and its placement with respect to the traditional families Tyrannidae, Pipridae and Cotingidae remain murky.

The peculiar and little-known White-naped Xenopsaris (*Xenopsaris albinucha*) occurs in marshy and shrubby, river-edge habitats in northern Argentina and Paraguay and in similar, open habitats in central Venezuela. Over the past hundred years, the genus has been transferred back and forth numerous times be-

Like the Myiarchus *flycatchers, members of the genus* Casiornis *tend to select an open perch overlooking dense vegetation. They slowly bob and swivel their heads, peering around in search of prey. When a suitable morsel has been detected, they usually sally outwards or downwards, snatching it during a brief hover-glean. Because it uses this technique, the bird regularly crashes into vegetation at the point of contact with the victim, then retreats to a nearby perch. In this case the bird is a* ***Rufous Casiornis****, the perch is a tree stump, and the victim is a moth.*

[*Casiornis rufus*, Minas Gerais, Brazil. Photo: Anita Studer]

tween the tyrant-flycatchers and the cotingas. The tarsal scutellation of *Xenopsaris* is of a type found primarily in the cotingas, and its plumage pattern, including a glossy black cap in the male, is similar to that of many *Pachyramphus*. Its compact, cup-shaped nest, built of grasses, is unlike the huge nest built by the becards, but, as a cup-shaped nest is presumably a primitive character in the Tyranni, this factor bears little information about relationships. Anatomical data support the hypothesis that this odd species represents a sister-group to *Pachyramphus*, but the fact that it possesses a unique second pair of internal syringeal cartilages, coupled with its primitive nest structure, argues for its retention in a separate genus.

The three species in the genus *Tityra* are completely unlike the rest of the Tyrannidae, and their systematic position remains as unclear as does that of *Pachyramphus*. They are chunky, sluggish, white-bodied, black-crowned birds of the tropical forest treetops. Allozyme and DNA-DNA hybridization data suggest that these two genera are closely related, perhaps representing their own subfamily within the Tyrannidae. Although this configuration, or a variant that places the group as basal to the rest of the Tyrannidae, is supported by some anatomical data, it is contradicted by others. Most importantly, *Tityra* was excluded from the putative "*Schiffornis* group" on the basis of its more primitive, cotingid-like syringeal characters; it lacks the internal cartilages present in *Pachyramphus* and other tyrannids. *Tityra* does, however, have an enlarged femoral artery, a highly unusual character that is absent in the Tyrannidae *sensu stricto*, but present in *Pachyramphus*, the "*Schiffornis* group", all piprids and most cotingids. Thus, the tityras do seem to belong within a group of tyrannoid genera that "float" in an intermediate, presumably basal systematic position outside any of the three narrowly defined families Tyrannidae, Pipridae and Cotingidae.

One may assume that, at the time of the separation of South America from Africa and Antarctica, early in the Tertiary, the principal passerine elements were ancestors of the present nonoscine families. Today, these families make up about 60% of the perching-bird fauna of South America. Early in the evolutionary history, the ancestral suboscines gave rise to two major independent radiations within the varied habitats of the Neotropics, especially in the great tropical forests. One lineage was to evolve into the complex of families now often classified as the Furnarioidea, or, as in the present work, the suborder Furnarii, which, in turn, is divided into two ecologically and morphologically distinct radiations: the first of these consists of the ovenbirds (Furnariidae) and the woodcreepers (Dendrocolaptidae), totalling 288 species; and the second comprises the two antbird families, Thamnophilidae and Formicariidae, the gnateaters (Conopophagidae) and the tapaculos (Rhinocryptidae), with a combined total of 335 species. This huge suboscine radiation is made up largely of foliage-gleaning insectivores that gather food by actively searching through vegetation and perch-gleaning, probing, tearing, and making short-distance sallies for relatively large prey.

The second major suboscine lineage to radiate during the Tertiary was the group that is usually referred to today as the Tyrannoidea, or, as herein, the suborder Tyranni, consisting of the modern Pipridae and Cotingidae, together containing 129 species, mostly specialized frugivores, and the huge family of Tyrannidae, which currently comprises 429 species, including its peripheral relatives. The Tyrannidae probably evolved from a generalized, partially frugivorous forest bird resembling today's tyrant-like manakins of the genera *Piprites*, *Schiffornis*, *Neopelma* and *Tyranneutes*. Many tyrant-flycatchers also include fruit in the diet, but the family achieved its success by expanding into the sallying-insectivore niche unoccupied by the Furnarii. Thus, flycatchers could spread into virtually all habitats that contained both insects and places in which to sit and search for them. The tyrannid search-and-sally foraging style was suited to well-illuminated forest edges more than to the forest interior. As a result, tyrannids today dominate in scrublands, forest canopies, forest clearings and lake and river margins far more than in the dark interior of the forest, where the Furnarii prevail. Despite a predisposition towards open habitats, however, the Tyrannidae did also succeed as forest-dwelling birds. Indeed, the family's species diversity reaches its global peak in the tropical forests of Amazonia and the Guianas, the coastal forests of south-eastern Brazil, and the subtropical forests of eastern Ecuador and Peru.

The suboscines obviously locked up most of the possible niches for avian insectivores and frugivores, and in the modern Neotropics they continue to co-exist in spectacular diversity. The major suboscine families have each a slightly different ecological focus with regard to foraging modes and food habits. All families established areas of peak diversity in the lowland rainforests,

*The **Pied Water-tyrant** is a conspicuous and easily identified species that spends much of its time on floating vegetation foraging for insects. In this instance, it has caught an aquatic insect from the water's surface and carried it to the nearest convenient perch, the raised bud of a lily flower. Unlike marsh-tyrants* (Arundinicola), *water-tyrants rarely sally into open airspace, instead usually nabbing their prey during quick sallies or darting runs. They also differ from marsh-tyrants in being sexually monomorphic, with both sexes sharing the same harlequin black-and-white pattern. Females incubate their eggs within a messy, globe-shaped nest in which she is entirely concealed. This species is a familiar sight in the low-lying hinterland of the Orinoco River in Venezuela, where individuals can be seen at most wetlands foraging amongst the herons and ibises.*

[*Fluvicola pica*, River Irakomkapi, Amana Natural Reserve, French Guiana. Photo: Thierry Montford/ Bios]

and only two of them, Furnariidae and Tyrannidae, successfully invaded the open habitats south of Amazonia and above the tree-line, exploitation of the latter being possible only after the relatively late rising of the Andes. Once South America and North America were connected, late in the Tertiary, oscine birds invading from the north could radiate widely in the Neotropics, either as fruit-eaters or as seed-eaters; as examples, the region now holds over 180 species of tanager, and 190 finches, buntings (Emberizidae) and grosbeaks (Cardinalidae). At the same time, the insectivorous families were, in contrast, limited by competition from the great suboscine radiations already present; South America has only 33 parulid warblers, 21 vireos, 57 New World blackbirds, 38 wrens, and 28 thrushes.

Morphological Aspects

Given the numerical dominance and ecological diversity of the Tyrannidae throughout the New World, it is not surprising that the family contains a wide assortment of morphological variations. A few specializations in the feathers of the wing, tail or crown are associated with social display, but the vast majority of the differences in body size, bill size and form, wing length and shape, tail structure, and leg and foot size are associated with different behavioural adaptations for foraging throughout the complete range of habitats of two continents. A detailed evaluation of the relationship between foraging mode and body form across the Tyrannidae, conducted by J. W. Fitzpatrick, provides background data for the observations summarized below.

Tyrant-flycatchers range in body size from the world's smallest passerine bird, the Short-tailed Pygmy-tyrant of the Amazon forest, weighing no more than 5 g, to the Great Shrike-tyrant, a hook-billed predator of the high southern Andes with a weight of 100 g. The family as a whole exhibits about the same distribution of body sizes as that found within the entire order Passeriformes, with most species falling in the weight range 10-30 g. The smallest tyrannids are members of the pygmy-tyrant and tody-tyrant group, birds that forage in dense vegetation and leap or flit explosively upwards to snatch prey; some of these weigh 6-10 g and have a wing chord measuring 45-55 mm. In this same size class are several wren-like species, such as the *Pseudocolopteryx* doraditos and the *Polystictus* tachuris, that live in tall grass and reedbeds. Only slightly larger are numerous genera of warbler-like and gnatcatcher-like tyrannids in the subfamily Elaeniinae, most of which actively forage high in forest canopy, *Ornithion*, *Zimmerius* and *Phylloscartes* being typical examples. As body size increases, pace of movement through the vegetation or across the landscape becomes more deliberate. The large number of middle-sized tyrannids forage with variations on the search-and-sally technique within vegetation of medium to low density, or by alternately running and stopping on open ground (see Food and Feeding). Examples of the former are the elaeniine genera *Pogonotriccus* and *Leptopogon*, and *Empidonax*, *Contopus* and their relatives in the Fluvicolinae, while the fluvicoline *Lessonia* and *Muscisaxicola* are typical of the latter strategy.

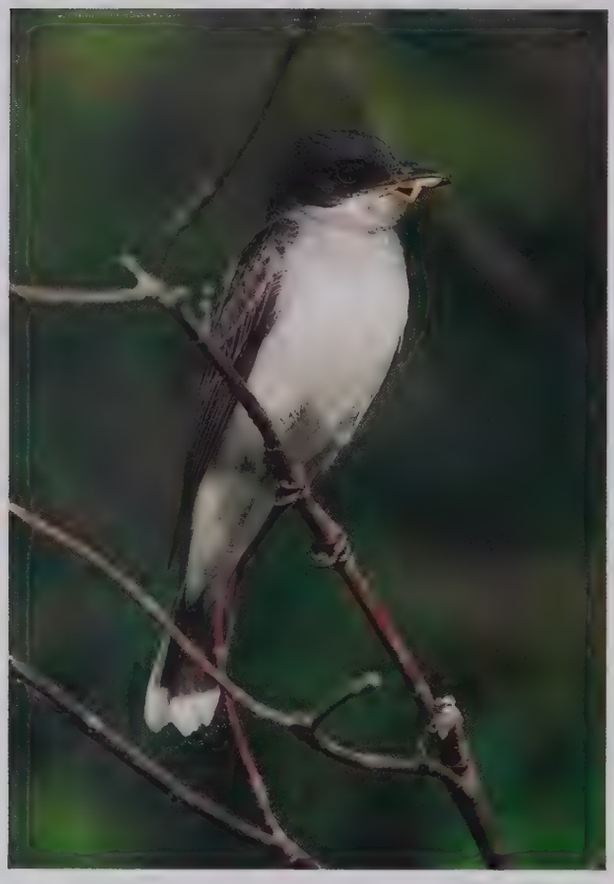
Two groups have evolved the largest bodies, and both live predominantly in open woodland or non-forest habitats. One of these is the fluvicoline radiation of *pampas*-dwelling monjitas, *Myiotheretes* bush-tyrants of the Andean tree-line and shrike-tyrants of the Andean *puna* and Altiplano, all of which search patiently on slightly elevated perches, sometimes for minutes on end, before sallying down or pouncing on prey. This predatory technique also typifies the Great Kiskadee in the Tyranninae, but most members of this large-bodied subfamily sally into the air for flying prey or, as in the case of, for instance, *Myiarchus*, *Megarynchus* and *Myiodynastes*, against leaves for large arthropods and fruit.

Because the bill of a tyrant-flycatcher is its primary tool for securing food, variation in size and shape of the bill within the family corresponds tightly with foraging mode. The most common bill type is broad at the base and roughly triangular in shape when viewed from above, and has a pointed and very slightly hooked tip. Relatively long versions of this bill shape typify most aerial hawkers, such as the genera *Tyrannus*, *Contopus*, *Mitrephanes* and *Hirundinea*, while species that sally into the air or outwardly against leaf surfaces within open vegetation, such as *Myiobius*, *Myiophobus*, *Empidonax*, *Cnemotriccus* and *Myiodynastes*, have somewhat shorter, wider versions of the basic triangular bill. Among those tyrannids that practise hover-gleaning, frequently hovering at the moment of prey capture following a sally, the triangular bill is somewhat deeper and narrower or more elongated, with a well-developed hook. Examples of species possessing this type include the *Leptopogon* and *Myiarchus* flycatchers.

The breadth of the triangular bill is developed to extremes among the flycatcher groups that specialize in "upward strik-

As it forages in open country from an elevated perch, ***Say's Phoebe*** *is often seen perching on man-made structures, such as utility wires and fence posts. It launches hawking flights from these perches in pursuit of airborne insects, including bees, wasps, ants, flies, beetles and butterflies. It often sallies over ponds and streams, attracted to the abundance of insects around aquatic habitats. Like many tyrant-flycatchers, it is so swift and manoeuvrable that even dragonflies are at risk. More often than not, the successful phoebe returns to the same perch with prey safely grasped between the mandibles.*

[*Sayornis saya saya*, New Mexico, USA. Photo: B. R. Hughes/ Windrush]



Manipulating large insects before swallowing them often involves beating the item against a branch, sometimes until the toughest body parts are broken, softened or removed. The prey item is then orientated lengthwise for easy swallowing. In tyrant-flycatchers the feet play no role in this process, and all manipulation is carried out using the bill. This ***Grey Kingbird*** *is dealing with a cicada, a robust homopteran with tough wings and carapace. This insect is so unwieldy that it cannot be swallowed backwards or sideways, and the kingbird needs to align it head first before attempting to swallow it.*

[*Tyrannus dominicensis dominicensis*, National Key Deer Refuge, Florida Keys, USA. Photos: Rob Curtis/ The Early Birder]

ing", in which the sallying bird flies upwards with a rapid burst to strike prey from an overhead substrate, usually the underside of a leaf, without hovering or pausing during the capture. Bills of upward strikers are all extremely broad farther out towards the tip, creating a spatula-shape with parallel edges, as in the *Todirostrum* tody-flycatchers, or a spade-shape in which the length of the bill is exceeded by its width, as in the *Platyrinchus* spadebills. In some cases, the bill is dorso-ventrally enlarged, often with a swollen-looking lower mandible, as exhibited by the flatbills in the genera *Rhynchocyclus* and *Tolmomyias*. Rictal bristles are quite pronounced among all these upward-striking species, and the extreme form both of the spatulate bill and of rictal-bristle development is found in *Onychorhynchus*, the Royal Flycatcher.

Contrasting with the broad bill of hawkers and strikers is the thin warbler-like bill of the perch-gleaners. These species have a bill shaped so as to act like tweezers, providing precision for picking prey items, often cryptic ones, from close range in hidden places. This bill shape is usually accompanied by little or no rictal-bristle development, as in the aptly named beardless tyrannulets and in the wren-like Many-coloured Rush-tyrant. A long, relatively thin bill is also a feature of larger-bodied, perch-

The larger tyrant-flycatchers are by no means restricted to insect prey. This ***Eastern Kingbird*** *is eating a tiny frog, and other kingbirds and relatives have been recorded consuming tadpoles, lizards, small snakes and even fish. The species that eat the largest prey, such as the genera* Attila *and* Agriornis, *tend to have a stronger hooks at the tip of the bill, this being used to prevent strong prey from escaping.*

[*Tyrannus tyrannus*, Dryden, New York, USA. Photo: Marie Read]

to-ground feeders such as the monjitas, which require the same kind of precision as the perch-gleaners as they pick prey from the surface of the ground or ground-cover vegetation after sallying down from above.

Tyrant-flycatchers that eat fruit most regularly, especially those that do so in all months of the year, have a short, slightly broadened bill somewhat convergent with those of the extensively frugivorous manakins. Examples include the Piratic Flycatcher and members of the related genus *Myiozetetes*, as well as most species of *Elaenia*. The rounded bill of the peculiar Sharp-tailed Tyrant may be associated with some degree of seed-eating in the species' grassland habitat (see Food and Feeding).

A few tyrannid genera regularly capture very large prey items, up to the size of small reptiles (see Food and Feeding). Irrespective of whether they snatch their prey from leafy vegetation in forests, as do the attilas, for example, or in open, temperate grasslands, as do the the shrike-tyrants, these species have a relatively long, strong bill with a well-developed hook at the tip.

The maxim that a jack-of-all-trades is a master of none can be applied to the shape of flycatcher bills. Species that use a variety of prey-capture techniques without specializing on any one have a bill that is of perfectly average dimensions when compared with the family as a whole. Perhaps the best example is the corvid-like bill of the Great Kiskadee.

Rictal bristles are very well developed in most tyrant-flycatcher groups, especially among those that sally hard into vegetation to snatch their prey. Proportionally the longest, most delicately curved bristles are those of the genera *Onychorhynchus*, *Myiobius* and *Terenotriccus*, a group with uncertain affinities but possibly monophyletic (see Systematics). Densely clustered, stiff bristles protrude around the face, eyes and bill of all species in the genus *Attila*, and of several of the larger *Agriornis* shrike-tyrants, including the related Chocolate-vented Tyrant (*Neoxolmis rufiventris*). This unusual condition presumably provides protection for the eyes against the flapping wings, sharply barbed legs or claws and noxious hairs of the very large food items taken by these predatory species. Indeed, in the case of the Willow Flycatcher, a sally-gleaning *Empidonax*, rictal bristles have been shown experimentally to reduce the contact between foreign objects and the eyeball. The tyrannids with the least developed rictal bristles are those that do little sallying but, instead, gather food by perch-gleaning in the manner of warblers. They include, among others, the genera *Camptostoma*, *Phyllomyias*, *Zimmerius* and *Inezia*.

Wing shape, as well as the ratio of body mass to wing area (wing-loading), varies considerably within the Tyrannidae. As with bill shape, this variation has been shown to correlate closely with foraging mode, but migratory behaviour adds a further, independent correlate. Short, rounded and highly cambered wings with high wing-loading are typical of birds that rarely or never engage in sustained flight but routinely require short, quick bursts of flight from the ground or a perch, as is typical of, for example, quails (Odontophoridae, Phasianidae) and grouse (Tetraonidae).

Many tyrant-flycatchers eat fruit, and a few are obligate frugivores. The ***Social Flycatcher*** *eats insects, but spends much of its time consuming berries. This is one of the most abundant and widespread birds in South America, almost constantly in sight or earshot in most humid lowland regions where open country or forest edge exists. This individual has been foraging on mistletoe (Loranthaceae) berries, which are large enough to be worth carrying away from the host plant, and which contain sticky seeds that adhere to a branch when regurgitated by the bird. This is a dispersal adaptation specifically aimed at frugivorous birds.*

[*Myiozetetes similis*, São Paulo, Brazil. Photo: Edson Endrigo]

*The **Great Kiskadee** is the supreme ecological generalist of the family. An opportunistic omnivore, it occupies a massive spectrum of foraging niches from downtown utility wires to the shores of ox-bow lakes in pristine Amazonian wilderness, from southern Texas to northern Patagonia. Its raucous and distinctive voice is one of the familiar sounds of the Neotropics. Adults visit ripe palm fruit, as shown here, but they also catch beetles, millipedes and reptiles. They will consume nestlings, carrion and municipal waste, and in parts of their range they forage in the style of kingfishers, plunging from a low perch to pluck a small fish or tadpole from water. Returning to the perch, the kiskadees then beat their prey senseless until it can be swallowed. One individual was seen to batter a 5 cm cichlid fish for over 13 minutes.*

[*Pitangus sulphuratus guatimalensis*, San José, Costa Rica. Photo: Marco Saborío]

*The **Ash-throated Flycatcher** in this photograph may have just quenched its thirst with a billful of water from a shrinking puddle, or, alternatively, it might just be poised to attack prey along the water's edge. It has been hypothesized, though not yet proven experimentally, that flycatcher species such as this, which live in arid habitats, consume all the necessary moisture through their diet of insects and fruit, as is the case with several other bird groups.*

[*Myiarchus cinerascens cinerascens*, south Texas, USA. Photo: Joe McDonald/DRK]

*The **Fork-tailed Flycatcher** occurs in large, harmonious flocks during the non-breeding and migration periods, but on their breeding grounds they are much less social and much more aggressive. They often chase rivals or prospective partners from perch to perch, as seen here, and males perform dramatic aerial displays. During such a display, the male flies upwards at an angle until he stalls, then he parachutes down in a spiral with wings held out and tail fanned, before regaining height once again. The remarkable outer tail feathers, elongated like old-fashioned shear-blades, no doubt assist in executing these spiral displays.*

[*Tyrannus savana savana*, Depresión del Salado, Buenos Aires, Argentina. Photo: Yves Bilat]

In the Tyrannidae, this lifestyle typifies the pygmy-tyrants, the tody-tyrants and the tody-flycatchers, as these species habitually sally upwards to snatch prey from the undersurfaces of leaves and, while foraging, make only short-distance movements between perches. All of these species, of which the Scale-crested Pygmy-tyrant (*Lophotriccus pileatus*) and the Common Tody-flycatcher are good examples, live in very small, permanent territories throughout the year and do not migrate. Possessing some of the smallest and most rounded wings in the avian world, these 52 species have the most limited dispersal ability of any group in the Tyrannidae. As a consequence, most of them have comparatively small ranges and exhibit pronounced local intraspecific differentiation, and many species groups show evidence of relictual distribution patterns, as is the case with, for example, the Buff-breasted, Cinnamon-breasted and Kaempfer's Tody-tyrants in the genus *Hemitriccus*.

At the other end of the spectrum in wing shape are the aerial-hawking specialists, for which rapid, sustained flight in the open air is essential for successful pursuit of fast-flying insects. Extreme examples occur in both the Fluvicolinae and the Tyranninae. Although no tyrant-flycatcher practises the "screening" foraging mode typical of swifts (Apodidae) and swallows, the generic name of the Cliff Flycatcher, *Hirundinea*, accurately implies that this species comes the closest, *Hirundo* being a well-known genus of swallows. Cliff Flycatchers are highly specialized aerial salliers, with tiny legs and feet and proportionally the longest wings in the Tyrannidae. As its English name implies, this species occurs almost exclusively in areas with high, exposed cliff faces, from which it sallies out as far as 100 m to snatch large flying insects. On occasion, it pursues these in protracted, acrobatic flight, and at such times, with its long, pointed wings and forked tail, it does resemble a swallow in both behaviour and form.

Proportionally long and pointed wings, with low wing-loading, also characterize the *Contopus* assemblage of pewees, which includes many species that engage in stereotyped aerial hawking from exposed perches and also migrate. The largest, longest-winged pewee is the Olive-sided Flycatcher, which moves between breeding grounds in the spruce bogs and high-elevation forests of northern North America and non-breeding quarters in the moist, forested slopes of the South American Andes. In both places, and along the way in between, this species characteristically perches atop the highest, most exposed treetop or snag, from which it launches upwards or outwards for up to 100 m to snap large flying insects. In mid-elevation montane forests of Central and South America, Olive-sided Flycatchers often share habitat with several smaller members of the genus *Contopus*, and with two allopatric species in the closely related genus *Mitrephanes*. These latter two, the Tufted Flycatcher and the Olive Flycatcher (*Mitrephanes olivaceus*), are, in effect, miniature pewees, with which they share both the aerial-hawking foraging mode and the unusually long and pointed wingtips.

The variously notched outer primaries of the kingbirds may have evolved from aerodynamic "slotting" of the wingtips, a feature typical of many groups of strong-flying birds. Among the 13 kingbird species, the most sedentary ones, such as the Loggerhead Kingbird (*Tyrannus caudifasciatus*), have normal-shaped primaries that lack notches altogether. Sharply attenuated outer primaries occur in some of the most migratory forms, such as the Scissor-tailed Flycatcher and the Western Kingbird (*Tyrannus verticalis*). Several species have deep notches in the outer two, five or six primaries, and the four subspecies of the Fork-tailed Flycatcher differ quite markedly from one another in the pattern of notching. In virtually all these cases, the notches are much more pronounced among males than among females, suggesting that they play either an aerodynamic or a sound-producing role in the males' fluttering aerial courtship displays (see Breeding).

A recurring feature in the wing design of many tyrant-flycatchers is that of oddly shaped flight-feathers within an otherwise structurally normal-looking wing. The affected feathers may be narrow and blade-shaped, narrow and pointed, reduced to half their normal length, slightly to deeply notched at the tip, notched subterminally on the inner webs, truncated at the tip, or even twisted. For the most part, these modifications are near the tip of the wing, in the outer primaries, and they are very often, although not always, confined to males. In the black-tyrant genus *Knipolegus*, most species have normal wings, but males of Hudson's Black-tyrant (*Knipolegus hudsoni*) and of the Amazonian Black-tyrant have three narrowed outer primaries, while males of the Cinereous Tyrant (*Knipolegus striaticeps*) have all ten primaries modified. Several other species possess single-feather modifications, as with the ninth primary of the Cock-tailed Tyrant (*Alectrurus tricolor*) and the tenth primary of the Black-and-white Monjita (*Xolmis dominicanus*). Modified inner primaries, with normal outer ones, are present in the genus *Mionectes*. The most extreme feather reduction, however, occurs in males of the monotypic genus *Atalotriccus*, the Pale-eyed Pygmy-tyrant, the

*The name "**Social Flycatcher**" is something of an exaggeration, as the species lives in pairs or small family parties, rather than flocks, and quickly repels intruders to its local territory. "Antisocial Flycatcher" might have been more accurate, especially given the racket it often makes from dawn till dusk around rural dwellings! At intervals throughout the day, pair members break into an unmusical and uncoordinated mutual calling, often accompanied by a frantic flapping of wings as shown here. These duets, which occur in a number of different tyrant-flyatcher groups, appear to serve both as a territorial signal and for strengthening the pair-bond.*

[*Myiozetetes similis*, São Paulo, Brazil. Photo: Edson Endrigo]

four outer primaries of which are so greatly reduced that they barely resemble flight-feathers at all; this species makes a peculiar, insect-like buzz with its vibrating wings. The Crested Doradito (*Pseudocolopteryx sclateri*) has two similarly reduced inner primaries, P6 and P7 being shortened and pointed, and micro-structural modifications of the barbules on primaries P6-P9, and this is a rare case in which the structural modifications of the flight-feathers have been shown to be associated with a wing-buzzing and popping sound that plays a role in the advertising song (see Voice). In the Brownish Twistwing, the basal portion of the primary shaft is uniquely stiffened, causing the distal portion to curve upwards and outwards, in addition to which the outer portion of the webbing flares upwards, owing to a weakening in the barbs. The function of this peculiar configuration remains unresolved, but it evidently plays a role in the mechanical-sounding display performed by the males. Clearly, there is much still to be learned about both the mechanical function and the biological significance of all these flight-feather modifications. High-speed videography will no doubt be required in order to resolve these mysteries.

Tail length varies more or less uniformly with body size within the Tyrannidae, but tail shape does differ somewhat according to foraging mode. The most deeply forked tail characterizes the aerial hawkers, such as members of the genera *Tyrannus*, *Contopus*, *Mitrephanes*, *Pyrrhomyias* and *Hirundinea*, as elongated outer rectrices assist the bird in making sharp turns and aerial manoeuvres in the open air. The most extreme versions, in which the outer rectrices may be three times longer than the wing chord, have evolved independently at least four times in species that forage mainly with aerial manoeuvres: twice in the genus *Tyrannus*, involving the Scissor-tailed Flycatcher and the Fork-tailed Flycatcher, and on separate occasions in two monotypic fluvicoline genera represented by the Streamer-tailed Tyrant and the Shear-tailed Grey Tyrant. In at least the first three cases, the exaggerated tail is used actively in courtship display (see Breeding), as well as during aerial sallies. A surprising additional example of the forked tail is provided by the little-known Fork-tailed Pygmy-tyrant, but its function is completely unknown, as this is a small, upward-striking *Hemitriccus* species that forages in dense vegetation. Finally, the greatly elongated, blade-shaped central rectrices of the Long-tailed Tyrant, similarly unmatched by any other member of the family, are unusual for any passerine bird. This is an obligate aerial-hawking flycatcher, but neither the central position of its elongated rectrices nor the relatively weak structure of these specialized feathers is consistent with an aerodynamic function. They trail behind the sallying bird more as a streamer than as a pair of "rudders", and they are highly variable in length from one individual to another. As females have shorter streamers than males, it appears that these elongated rectrices are utilized in advertisement, rather than as mechanical aids during foraging.

The peculiarly tiny tail exhibited by several genera appears to be virtually vestigial. Members of the genus *Myiornis*, especially the superspecies formed by the Black-capped and Short-tailed Pygmy-tyrants, accomplish foraging manoeuvres by means of a peculiar flight that approaches hovering, in which the tail plays no aerodynamic role. The appropriately named Short-tailed Field-tyrant, in the monotypic genus *Muscigralla*, has a very short tail and is exclusively terrestrial. It forages by alternately running and standing in an upright posture, and in behaviour and morphology it is typical more of a shorebird than of a flycatcher.

What must be the oddest tail structures in the family belong to the two species in the genus *Alectrurus*. The explorer W. H. Hudson described that of the Cock-tailed Tyrant in the following words: "the two outer tail-feathers have remarkably stout shafts, with broad coarse webs, and look like stumps of two large feathers originally intended for a bigger bird, and finally cut off near their base and given to a very small one". These feathers are often held cocked at a sharp angle, resembling the tail of a miniature rooster, hence the English name for this species. In the other member of this genus, the Strange-tailed Tyrant, the outer tail feathers of the male, and to a lesser extent those of the female, are greatly elongated but, in contrast to the Shear-tailed Grey and Streamer-tailed Tyrants, not in an aerodynamically strengthening fashion. Instead, the greatly elongated shaft is bare at the base and carries a terminal pennant. In both cases, the peculiar tail is employed in elaborate aerial displays by the black-and-white males, as the cryptically brown females remain barely visible within the grass or reeds below. The extreme sexual selection evident in these two grassland species makes it virtually certain that they have a polygynous social system (see Breeding).

Among the tyrant-flycatchers, the Sharp-tailed Tyrant is unique in having only ten rectrices, each of which is stiffened and bears degenerated barbs. This tiny elaeniine lives exclusively in open grassland, where it perches on grass stems and small

shrubs. The tail is held vertically downwards and often in contact with the grass stalk below the perched bird, suggesting that its stiffness perhaps serves a bracing function.

Tarsus length and the size and strength of the foot correlate extremely closely with foraging mode. The longest legs in proportion to body size belong to those species that forage predominantly on the ground or regularly fly to the ground from an elevated perch. This ecomorphological condition has arisen a number of times independently across the family, as demonstrated by, among others, the genera *Corythopis*, *Machetornis*, *Muscigralla* and *Muscisaxicola*. The most powerful legs and feet are those of the monjitas, the bush-tyrants in the four genera *Myiotheretes*, *Cnemarchus*, *Polioxolmis* and *Neoxolmis*, and the *Agriornis* shrike-tyrants, all of which are predatory perch-to-ground specialists. The Galapagos Flycatcher, a *Myiarchus* species, illustrates the selective pressure for increased tarsus length with increasing use of the ground. Its proportionally long legs and its tendency to sally to the ground both stand out within an otherwise morphologically and behaviourally uniform genus. Other examples include the Torrent Tyrannulet and the three phoebes. Two tyrannids, the Austral Negrito (*Lessonia rufa*) and the Strange-tailed Tyrant, have extraordinarily long hind claws, closely resembling those of certain Old World pipits and longclaws of the family Motacillidae. The mechanical function of these claws is not known conclusively, but they presumably provide considerable extra support for walking on mats of wet or floating vegetation, as these two groups regularly do.

Long, slender legs and toes are associated with the habit of frequently using vertical or near-vertical perches, and represent a morphological convergence with the wrens. Examples include the two wagtail-tyrants in the genus *Stigmatura*, the *Todirostrum* tody-flycatchers, the two tachuris in *Polystictus*, and the Many-coloured Rush-tyrant. Short, slender legs and rather weak feet are typical of the aerial hawkers, and once again the Cliff Flycatcher, the Cinnamon Flycatcher and the pewees present the most extreme examples.

Habitat

Tyrant-flycatchers are found in every terrestrial habitat in the New World with the exception of the high-Arctic tundra. They occur as far north as the stunted black spruce bogs near the Arctic Circle, and as far south as the rocky, treeless terrain of Tierra del Fuego. The enormous evolutionary success of the Tyrannidae is at least in part a consequence of the myriad adaptive variations that its species have made from the "search and sally" foraging style typical of the family as a whole. This hunting strategy gives access not only to aerial prey, but also to prey substrates that include the ground as well as leafy vegetation, and makes the undersides of leaves just as accessible as their upper surfaces. Thus, whether the habitat is rainforest, deciduous woodland, coniferous woods, arid scrub, sagebrush (*Artemisia*) or cactus desert, open *campo*, or mountaintop grassland, tyrant-flycatchers have adapted their foraging styles to enable them to gain access to whatever arthropod and small-fruit resources these habitats provide.

Across the Neotropics, tyrant-flycatchers are especially diverse within micro-habitats where light intensity is highest, and they dominate the "outer edges" of resource-rich habitats such as forest canopy, forest edge, scrub and second growth. In contrast to the Tyrannidae, the other two major Neotropical radiations of suboscine insectivores, the formicariids and thamnophilids, and the furnariids and dendrocolaptids, predominate in forest understorey, dense thickets, vine tangles and leaf litter, where foliage density is higher, light intensity is lower, and prey are best located and captured by probing, picking or pouncing.

Tyrannid diversity is proportionally highest in desert and scrub habitats of western North America, Middle America and tropical South America, where the total avian species diversity is low. Flycatchers can comprise up to half of the passerine avifauna in the most arid, species-poor lowland deserts. Across the desert scrubs of northern Venezuela, for example, where the most barren landscapes have just a few widely scattered, knee-high shrubs and low cacti, four of the ten resident passerines are tyrant-flycatchers; these are the Southern Beardless Tyrannulet (*Camptostoma obsoletum*), the Northern Scrub-flycatcher (*Sublegatus arenarum*), the Brown-crested Flycatcher and the Vermilion Flycatcher. As soil moisture and density of scrub vegetation increase within this region, the flycatcher community steadily becomes more diverse as species are added in quite predictable sequence. First to join are the tiny Slender-billed Tyrannulet, the Mouse-coloured Tyrannulet, the Pearly-vented Tody-tyrant (*Hemitriccus margaritaceiventer*), the Cattle Tyrant and the Great Kiskadee. Where scattered taller *Acacia* bushes and small trees appear in the arroyos, they are colonized by further species, including the Maracaibo Tody-flycatcher, the Pale-eyed Pygmy-tyrant, the Fuscous Flycatcher and the Tropical Kingbird. Where arroyo vegetation becomes tall and dense, still others are added to the tyrannid community with the appearance of the Pale-tipped Tyrannulet, the Yellow-breasted Flycatcher, and the Bran-coloured and Dusky-capped Flycatchers. Finally, in areas where scrub vegetation is tall and dense with an overstorey of deciduous trees, as many as ten additional tyrannids join the passerine community, which now includes the White-throated Spadebill (*Platyrinchus mystaceus*), the Olivaceous Flatbill (*Rhynchocyclus olivaceus*), the Bright-rumped Attila, several elaenias, and a number of large tyrannines such as the Streaked Flycatcher. In these semi-deciduous woodlands, tyrant-flycatchers comprise about 25% of the total passerine community.

High in the Andes, in the arid Altiplano, the *puna* and *páramo* zones, and rocky cliffs above the tree-line, the tyrannids are represented only by the *Muscisaxicola* ground-tyrants, a few bush-tyrants and shrike-tyrants. The high-Andean *Polypepis* woodlands also occasionally harbour tit-tyrants, and the rare and globally threatened Ash-breasted Tit-tyrant (*Anairetes alpinus*) is restricted to a few patches of this most distinctive, highly endangered habitat at elevations above 4000 m (see Status and Conservation).

At slightly lower elevations, in the shrubby interface where composites, *Lupinus*, *Berberis* and other low shrubs interlace with tussock grasses and elfin forest on the humid Andean slopes, the tyrant-flycatcher community quickly diversifies. Here, several species of warbler-like *Mecocerculus* tyrannulets, high-elevation elaenias such as the White-crested (*Elaenia albiceps*) and Sierran Elaenias (*Elaenia pallatangae*), up to four species of *Ochthoeca* chat-tyrants and up to four *Myiotheretes* bush-tyrants, the beau-

Displays of tyrant-flycatchers often contain useful taxonomic information, as was recently shown by studies of the Suiriri Flycatcher (Suiriri affinis). *It has long been known that pairs of this species sometimes perch side-by-side to give a duet, accompanied by a raising and flapping of the wings, and a spreading of the tail. Only very recently, however, was it noticed that some pairs performed these displays and others did not. This intriguing discovery, and the intensive field research that ensued, led to the description of a new species: the* ***Chapada Flycatcher***.

[*Suiriri islerorum*, Das Emas National Park, Goiás, Brazil. Photo: Johannes Ferdinand]

tiful Ochraceous-breasted Flycatcher, and even a high-elevation tody-tyrant, the Black-throated Tody-tyrant (*Hemitriccus granadensis*), can occur together.

The mid-montane cloudforests of the eastern Andes support mainly small-bodied flycatchers, with a number of genera represented by "elevational series" in which species replace one another up the elevational gradient. In southern Peru, for example, the genus *Myiophobus* is represented at low elevations of 250-1450 m by the Bran-coloured Flycatcher, and in lower cloudforest at 1000-2150 m by the little-known Unadorned Flycatcher (*Myiophobus inornatus*). Above these, the Handsome Flycatcher (*Myiophobus pulcher*) is found in full cloudforest at 1500-2600 m, and, highest of all, the Ochraceous-breasted Flycatcher lives at 2200-3400 m in upper cloudforest and elfin forest. The genera *Phyllomyias* and *Zimmerius* of small, perch-gleaning, treetop tyrannulets together contain a similar series of elevational replacements across the same gradient: the Slender-footed Tyrannulet (*Zimmerius gracilipes*) occupies tropical elevations, the Red-billed and Rough-legged Tyrannulets occur from 500 m to 1500 m, the Bolivian (*Zimmerius bolivianus*) and Ashy-headed Tyrannulets (*Phyllomyias cinereiceps*) live in the middle cloudforest zone at 1200-2000 m, and the Tawny-rumped Tyrannulet (*Phyllomyias uropygialis*) occupies the upper cloudforest zone at altitudes of 1800-3000 m. The Bronze-olive Pygmy-tyrant (*Pseudotriccus pelzelni*) lives in dense understorey thickets of lower cloudforest, and is replaced in similar habitats above 1800 m by the spectacular little Rufous-headed Pygmy-tyrant (*Pseudotriccus ruficeps*). Throughout the eastern Andes, the Slaty-capped Flycatcher (*Leptopogon superciliaris*) is a common tyrannid in mixed-species flocks at lower to medium-elevation cloudforest, and is abruptly replaced above 2000 m by the Inca Flycatcher (*Leptopogon taczanowskii*) in Peru, and by the Rufous-breasted Flycatcher (*Leptopogon rufipectus*) in Ecuador and Colombia. In contrast to these sequential elevational replacements, up to four species in the *Pogonotriccus* and *Phylloscartes* bristle-tyrant complex sometimes occur together in the humid upper tropical forests of the eastern Andes, at elevations of around 1000 m.

Peak diversities among tyrant-flycatcher communities occur at elevations below 1000 m in South America. In the Amazonian lowlands, more than 80 flycatcher species can be found at a single locality. Such staggering diversity occurs where a variety of resource-rich habitats come together, including floodplain-forest and *terra firme* forest, river edges, beaches and early-successional *Tessaria* thickets, canebrakes, *Heliconia* swamps, oxbow lakes, grassy marshes, bamboo stands, and *Mauritia* palm swamps. Tyrannid communities of the interior forest across the Amazon Basin can include up to 30 species, mainly in the 20 genera *Leptopogon*, *Mionectes*, *Elaenia*, *Myiopagis*, *Tyrannulus*, *Corythopis*, *Todirostrum*, *Myiornis*, *Hemitriccus*, *Myiobius*, *Onychorhynchus*, *Terenotriccus*, *Tolmomyias*, *Ramphotrigon*, *Attila*, *Rhytipterna*, *Sirystes*, *Myiarchus*, *Pachyramphus* and *Tityra*. Along river margins and Amazonian lakeshores, up to 15 species of large-bodied, omnivorous tyrannine flycatchers of ten different genera can occur together. These are augmented along brushy margins of rivers, accreting beaches and oxbow lakes by an additional 20 tyrant-flycatcher species representing a further 17 genera.

Ecological and geographical segregation is extremely finely developed within the tody-tyrants and pygmy-tyrants, a numerically rich assemblage of small-bodied species that are remarkably similar to one another in both morphology and behaviour. In south-eastern Peru, where avian diversity reaches its peak, nine different species in this lineage can be found within a single square kilometre, yet few of them are likely to see one another because each occurs in a different micro-habitat. Highest in the canopy of tall, even emergent trees is the Yellow-browed Tody-flycatcher (*Todirostrum chrysocrotaphum*). The Short-tailed Pygmy-tyrant inhabits the dense, viny edges of old blowdown openings midway up in tall forest canopy, while the White-eyed Tody-tyrant (*Hemitriccus zosterops*) forages in the darker mid-storey of the forest interior. Occupying seasonally flooded, leafy thickets at the river margins is the Spotted Tody-flycatcher (*Todirostrum maculatum*). Where the slow-moving rivers sweep around wide bends, dense stands of the tall cane *Gynerium sagittatum*, known locally as "*caña brava*", produce an impenetrable understorey habitat for the Rusty-fronted Tody-flycatcher (*Poecilotriccus latirostris*). In places where primary succession is further advanced, older cane stands become overshadowed by *Cecropia* trees, interspersed with *Heliconia*, and filled with dense, viny openings caused by the ravages of rainy-season floods. This productive and heterogeneous *matorral* zone is the habitat of

*The **Streamer-tailed Tyrant** is a distinctive species with a dark breastband, cinnamon wing panels, and an elongated tail. These features, and also its internal anatomy, have led to its placement in a monotypic genus of uncertain affinities within the Fluvicolinae. Pairs often engage in a magnificent display which might be to do with territorial signalling as much as with courtship and pair-bond maintenance. They perch together prominently, facing either in the same or directly opposite directions, and produce a volley of piercing whistles, warbles and bill-popping sounds. This vocal outpouring is accompanied by a raising and flapping of the wings and a rhythmical raising and fanning of the tail.*

[*Gubernetes yetapa*, Serra da Canastra, Minas Gerais, Brazil. Photo: Edson Endrigo]

Most species in the genus Knipolegus *engage in a spectacular back-flipping display initiated from an open branch. Here performed by a* ***White-winged Black-tyrant****, it begins with a quick vertical flight, usually 1-3 m in height, at the summit of which the male stalls upright, with his head at the top, his tail pointing vertically downwards and his feet held out. Then he topples over with half-closed wings (as seen in the right-hand photo) and drops back down, opening his wings just before he reaches the perch. He executes this charming performance every half-minute or so, usually producing a small grating "*erk*" note during the flight.*

[*Knipolegus aterrimus aterrimus*, Talampaya National Park, La Rioja, Argentina. Photos: José & Adriana Calo]

Johannes's Pygmy-tyrant (*Hemitriccus iohannis*). Finally, no fewer than three species of pygmy-tyrant, in three different genera, occupy different types and sizes of *Guadua* bamboo stands. These are the Flammulated Pygmy-tyrant (*Hemitriccus flammulatus*), which occurs in large, pure stands of dense bamboo; the White-cheeked Tody-tyrant, found in taller, older stands; and the Long-crested Pygmy-tyrant (*Lophotriccus eulophotes*), which appears to occupy transitional habitats that include both bamboo and leafy thickets, sometimes occurring in river-edge forest lacking bamboo altogether.

Tyrant-flycatchers are well represented among the many bird species that have become ecological specialists in *Guadua* bamboo thickets of the southern Amazon and in south-eastern Brazil. Besides the two bamboo-restricted species just mentioned, the Yellow Tyrannulet and the Large-headed Flatbill occur mainly in bamboo over much of their Amazonian ranges, while in south-eastern Brazil the Brown-breasted (*Hemitriccus obsoletus*) and Drab-breasted Pygmy-tyrants (*Hemitriccus diops*) are found largely in bamboo thickets. Similarly, in the eastern Andes, two distinctive *Anairetes* species, the Agile and Unstreaked Tit-tyrants, are found mainly in association with *Chusquea* bamboo stands high in the cloudforest.

Two of the five species of *Serpophaga* have specialized in living at the edges of streams and small rivers. One of these, the Torrent Tyrannulet, occurs in the middle and lower elevations of the Andes along rocky streams, where it flits actively from the tops of rocks to snatch both flying and stationary prey at the edges of fast-flowing water. The other, the Sooty Tyrannulet (*Serpophaga nigricans*), lives along the brushy edges of slower-moving streams and the edges of ponds in southern Brazil and northern Argentina. The Drab Water-tyrant, a widespread flycatcher of the Amazon Basin, is restricted to debris-covered and rubble-strewn banks of larger, seasonally flooding rivers where clay or mud banks are exposed. The Riverside Tyrant and the Lesser Wagtail-tyrant (*Stigmatura napensis*) occur along the Amazon itself and, in the former case, also the Orinoco River, where they are confined to regularly flooded, early-successional vegetation along the larger river islands. Like the Riverside Tyrant, the congeneric Amazonian Black-tyrant is similarly restricted to Amazonian and Orinoco river-edge habitats, but it forages deeper in the recesses of seasonally flooded forest and often sallies to the water's surface.

A handful of tyrant-flycatchers have specialized on open grassland and marsh habitats, and many of these represent some of the most unusual species in the family. The monotypic Sharp-tailed Tyrant is restricted to the few areas where large expanses of dry *campo* grassland still exist in central Brazil, eastern Bolivia, eastern Paraguay and northern Argentina. It shares these open grassland habitats with another peculiar tyrannid, the Cock-tailed Tyrant. Both species are becoming increasingly rare as agricultural conversion continues throughout their native habitats (see Status and Conservation). The beautiful Many-coloured Rush-tyrant is widely but locally distributed in southern South America, occurring in both coastal and temperate-zone marshes from Andean Peru southwards through Argentina and Chile, and in marshy lowlands from southern Brazil to Patagonia. Another southern species, the Spectacled Tyrant, breeds in Patagonian marshes and reedbeds, and feeds in adjacent open flats and floating vegetation; during migration and winter, it occurs irregularly in similar habitats high in the Andes of Chile, Argentina, Bolivia and Peru. The four doraditos in the genus *Pseudocolopteryx* and the two tachuris in *Polystictus* are locally distributed in wet grass habitats, mainly in southern South America.

The open *Prosopis* scrub and woodland of Mexico and the south-western USA, on the one hand, and those of central Argentina, on the other, harbour ecologically similar but taxonomically very different passerine communities. Tyrannid diversity is low in the Mexican arid scrublands, although up to four species in the genus *Myiarchus* may be found together, these being the Ash-throated, Brown-crested, Nutting's (*Myiarchus nuttingi*) and Dusky-capped Flycatchers. In the Argentine *monte* deserts, this scrub habitat holds a disproportionately high number of Tyrannidae, with several monjitas, and tyrannines such as the Fork-tailed Flycatcher and Crowned Slaty Flycatcher, along with the Vermilion Flycatcher and a number of arboreal perch-gleaners, including the Greater Wagtail-tyrant (*Stigmatura budytoides*). In this distinctive habitat, the dense, deciduous chanar tree (*Geoffroea decorticans*) provides nest-sites for many of the

*This male **Black-crowned Tityra** is carrying a leaf, probably intended as nesting material. Tityras do not build nests as such, but they do line the floor of natural cavities with scraps of vegetation, bark and dead leaves. In most tyrant-flycatchers the female takes sole responsibility for nest building and incubation, although often the male looks on with interest throughout the process. It is not uncommon, however, for males to bring supplementary nest material or food for the female during the incubation period.*

[*Tityra inquisitor inquisitor*, Iguazú National Park, Misiones, Argentina. Photo: Julián M. Alonso]

tyrannids. As an example, 98% of the nests of White-bellied Tyrannulets (*Serpophaga munda*) found in various studies were in chanar trees.

Many savanna-inhabiting flycatcher species have discontinuous ranges in South America, occurring both in the *llanos* and grasslands of the Guianan Shield and in the larger stretch of open country stretching from north-eastern Brazil south-westwards to the Argentine *pampas*. A few of these widespread open-country tyrannids are austral migrants in the southern portion of their range or are highly migratory and move great distances, the Cattle Tyrant and the Fork-tailed Flycatcher being two respective examples, and such movements help to explain their occurrence on both sides of the vast Amazon forest. Other open-country tyrannids, however, are sedentary and not known to migrate at all, the Tawny-crowned Pygmy-tyrant being a typical example. The distributions of these are presumed to reflect large-scale historical changes in the vegetation of South America, as may have occurred, for instance, during global cool spells (glacial maxima). During such dry periods, savanna habitats are thought to have penetrated, and possibly severed, the Amazonian forest, thereby allowing grassland birds such as the Bearded Tachuri (*Polystictus pectoralis*) to disperse across the South American lowlands. As climate changed and the forests returned, these specialized species became isolated in the discontinuous regions of open habitat that exist today.

Temperate grasslands of North America, the "Great Plains", support the largest radiation of kingbirds, although it is rare to find more than two species in any one spot. The widespread Eastern Kingbird (*Tyrannus tyrannus*) occupies the most mesic habitats, and even breeds along forested creeks and beside beaver (*Castor*) ponds, as well as in open grassland. The Western Kingbird is the common kingbird across the wide-open, northern Great Plains, while the very similar Cassin's Kingbird (*Tyrannus vociferans*) occurs in drier, more southerly prairie habitats where trees dot the landscape along creek beds. The Scissor-tailed Flycatcher is the kingbird of the southern Great Plains where open, shrubby grasslands prevail. Couch's Kingbird (*Tyrannus couchii*), virtually restricted to Mexico, inhabits the dry scrubland and scrubby savannas of eastern Mexico, extending north to the USA border.

A four-species assemblage of tyrant-flycatchers, representing four different genera, is ubiquitous across the deciduous forests of eastern North America, being joined in certain habitats by "extra" species of *Empidonax*. The core quartet consists of the Great Crested Flycatcher, hover-gleaning in the treetops, the Eastern Wood-pewee, practising aerial hawking in the open middle storey, the Eastern Phoebe (*Sayornis phoebe*), which feeds by aerial hawking and perch-to-ground gleaning near cliff faces and man-made structures, and the Least Flycatcher (*Empidonax minimus*), sally-gleaning in forest openings, edges and abandoned orchards. In addition, the Willow Flycatcher lives in open brush, second growth and riparian zones, and its northerly replacement, the Alder Flycatcher, breeds in alder (*Alnus*) swamps, while the

*As in most tyrant-flycatchers, the female **Grey-capped Flycatcher** is the only member of the pair to build the nest, while her mate watches from a nearby perch. This species builds an untidy ball of grasses with a side entrance, lodging the whole structure in a forked branch or cavity, usually in open situations and often over water. Very often, the female may steal nesting material from other active bird nests, and occasionally the pair will actually take over another bird's nest entirely, in the manner of their close relative the Piractic Flycatcher* (Legatus leucophaius).

[*Myiozetetes granadensis granadensis*, Cachí de Cartago, Tapantí National Park, Costa Rica. Photo: Marco Saborío]

*The **Common Tody-flycatcher** is a familiar bird of mature gardens, shrubland and patchy woodland in tropical Central and South America. Like all species in the tody-tyrant and pygmy-tyrant lineage, it builds a hanging pouch-shaped nest with a side entrance. This individual is putting the finishing touches to the long strap by which the pouch is attached to a twig. Typical characteristics of this species are that it incorporates random articles into the outer surface of its nest, and that it binds the structure together with spiders' webs. This technique tends to produce a messy effect, which presumably helps conceal the nest from predators. In this case, the camouflage is rather decorative as the bird has chosen to stitch some bright flowers into the walls of its home. Some members of the genus* Todirostrum, *including this species, have a strange display in which they hitch sideways along a perch with the wings drooped, and the tail cocked almost vertically over the head and waggled enthusiastically from side to side, all the while delivering a series of metallic "tic" sounds. Note the markedly rounded wings typical throughout the tody-tyrant and pygmy-tyrant lineage.*

[*Todirostrum cinereum wetmorei*, Panama. Photo: Marie Read]

The design of tyrant-flycatcher nests reveals evolutionary relationships and can help to resolve taxonomic issues. The ***Lesser Kiskadee*** *was traditionally placed in the genus* Pitangus, *but several unique features led to its reassignment to a monotypic genus,* Philohydor. *In addition to the substantial differences in syringeal structure and voice, the two kiskadees build very different nests.* Pitangus *builds an untidy spherical affair, while* Philohydor *builds an open cup often made of vine tendrils. This adult is in the process of nest construction, apparently making use of a spider's nest as a foundation. Many species of tyrant-flycatcher in most taxonomic groups encompass spider webs and spider egg sacs into their nest walls.*

[*Philohydor lictor lictor*, Alta Floresta, Mato Grosso, Brazil. Photo: Edson Endrigo]

Acadian Flycatcher (*Empidonax virescens*) occupies the dark interiors of southern hardwood forests and, in the north, ravines dominated by hemlock (*Tsuga*).

The vast coniferous-forest zone that stretches from coast to coast across North America supports only a few tyrannids. The Olive-sided Flycatcher occurs throughout and, in the west, extends southwards through the higher elevations of the Rocky Mountains and the Sierra Nevada. The Yellow-bellied Flycatcher (*Empidonax flaviventris*) breeds in eastern coniferous habitats, especially black spruce bogs, while Hammond's Flycatcher (*Empidonax hammondii*) is found throughout western spruce-fir habitats from northern Alaska south to the central Rockies. The latter's replacement in more open and mixed hardwood-conifer habitats is the Dusky Flycatcher (*Empidonax oberholseri*), and in the arid juniper (*Juniperus*) and sagebrush of the Great Basin its place is taken by the rare Grey Flycatcher.

Tyrant-flycatchers in a variety of groups benefit from habitat alterations associated with agriculture and grazing. Orchards and nurseries, for example, are home to Least Flycatchers in North America. Brushy second growth and overgrazed scrublands in the tropics support dozens of tyrannids, and have probably enabled such species as the Mouse-coloured Tyrannulet, the Tawny-crowned Pygmy-tyrant and the Fuscous Flycatcher to become more common today than they ever were in the past.

The Great Kiskadee has greatly expanded its geographical range, elevational tolerance and overall abundance across much of Central and South America, mainly as a consequence of forest clearance. This conspicuous tyrannid, likely originally to have been mainly a river-edge and lakeshore species, now occurs even in densely forested regions wherever man-made clearings of sufficient size exist. Besides using a variety of naturally open habitats and water margins, the kiskadee will forage in agricultural lands, along roadsides and hedgerows, and in suburban gardens and city parks, and it often nests in such areas, too. The Great Kiskadee is now common in a variety of suburban settings in Bermuda, where it was introduced in 1957. Similarly, the Common Tody-flycatcher is a regular inhabitant of ornamental shrubbery planted alongside houses, garden borders and plazas in the tropics.

Another tyrannid that is growing increasingly common as a commensal with man is the Cliff Flycatcher. This inhabitant of exposed cliff faces is now seen frequently around human habitations, even in some of the most bustling cities of South America, such as São Paulo, where it regularly perches and occasionally even nests on window or roof ledges, and frequently uses utility poles and wires as foraging posts.

General Habits

Because tyrant-flycatchers are so numerous and diverse, only a few general habits can be said to characterize the family as a whole. So far as is known, all species are diurnal and, although they wake up very early in the day, they appear to begin active foraging somewhat later in the dawn hours compared with some other avian groups. As described below (see Voice), many species of tyrant-flycatcher are among the first birds to sing in the pre-dawn light, and a large proportion of these early singers do so with a specialized "dawn song". The family's roosting habits are poorly documented, but most species spend the night perched quietly within dense vegetation. Those tyrannids that nest in cavities, such as members of the genera *Myiarchus* and *Myiodynastes*, may roost in these same cavities even when no eggs or young are present, but only one genus that builds an external nest, *Rhynchocyclus*, is known to use it as a dormitory for roosting outside the breeding period.

Most tyrannids spend a good part of the day actively foraging. As with most birds, peaks of activity occur during several hours just after dawn and in the late afternoon. Because most tyrant-flycatcher species use some version of the search-and-sally foraging style (see Food and Feeding), for much of the time a typical tyrannid is sitting still, with just the head actively moving around in search of prey, and occasionally either sallying to attempt a prey capture or moving to a new perch. Most species have a rather upright perching position, with the head held high and the bill at or slightly above the horizontal, and with the tail held nearly vertically downwards, although there are numerous exceptions to this general rule. While otherwise sitting still on a

Elaenias build relatively small and beautifully neat cup-shaped nests. They usually balance them on top of horizontal branches in large bushes or low trees, but this ***Plain-crested Elaenia*** *has placed it in an upright fork, maintaining stability by using narrow twigs as stanchions, and fixing the nest to them with spiders' webs. This species inhabits open* cerrado *habitats, where trees are infrequent, and most of its nests are placed in low shrubs. The two mouths inside this nest reveal the commonest size of clutches and broods for tropical tyrant-flycatchers.*

[*Elaenia cristata cristata*, Maranhão, Brazil. Photo: Anita Studer]

perch, many tyrannid species flick or pump the tail in characteristic rhythms or patterns. These tail movements are variously upwards, as typified by, for instance, the *Sayornis* phoebes, downwards, as in the case of certain *Empidonax* species, for example, or from side to side, as with the *Knipolegus* black-tyrants and some others; in some cases, the tail feathers are alternately fanned and closed, a habit typical of the *Stigmatura* wagtail-tyrants and a few other genera. Many species vocalize at regular intervals throughout the day while they are foraging or resting.

The social systems of tyrant-flycatchers are uniformly simple. Indeed, for a family as diverse and ecologically variable as the Tyrannidae, the lack of diversity in social organization is somewhat surprising. Virtually all species breed as territorial pairs (see Breeding), and most of the non-migratory tropical species appear to live throughout the year as simple pairs or small family groups on defended territories. Even when paired, many of these same species are as likely to forage solitarily as they are to feed together with the mate and offspring. A large proportion of the smaller-bodied, treetop-dwelling flycatcher species in the tropics and in forested habitats of the mountains regularly or always forage in mixed-species flocks, typically joining other species of tyrannid, along with tanagers, warblers, antbirds, furnariids, dendrocolaptids and woodpeckers (Picidae). Tyrant-flycatchers that live in the forest understorey also forage in mixed flocks, but seemingly less often than do those that live in the treetops. No tyrannid is gregarious throughout the year, but a number of species, especially in the genus *Tyrannus*, do travel in flocks containing dozens to hundreds of individuals during the migration and non-breeding periods (see Movements).

Nocturnal roosting is generally solitary, although the young fledglings of many species may roost in close proximity to, or even in physical contact with, one another. The Eye-ringed Flatbill (*Rhynchocyclus brevirostris*), and presumably its congeners, often roosts in the nest outside the breeding season, and apparently even builds "dormitory nests" for this purpose. This behaviour is unique within the family, although females of most of the cavity-nesting species will roost in the nest for several nights prior to egg-laying. A number of the large-bodied, yellow-bellied flycatchers in the subfamily Tyranninae frequently roost and, at times, nest in the same shrub or tree, usually an isolated, dense tree in a clearing or along a lakeshore. One large shrub beside a south-eastern Peruvian lake, for example, contained a roosting pair of Great Kiskadees, three Lesser Kiskadees, two Social Flycatchers, two Grey-capped Flycatchers (*Myiozetetes granadensis*) and a Tropical Kingbird. A large fig tree (*Ficus insipidus*) overhanging the same lakeshore held simultaneously active nests of the first four of these species.

Many species of tyrant-flycatcher engage in conspicuous display behaviour, most often in association with courtship interactions within a pair or aggressive encounters between two males. A number of species in different tyrannid groups have a concealed or semi-concealed crown patch, which may be white, as, for example, in the genus *Elaenia*, yellow, as in *Myiopagis*, *Tyrannulus*, *Myiotriccus*, *Myiophobus* and others, orange, as in many of the large-bodied tyrannines such as *Tyrannus*, *Pitangus*, *Myiozetetes* and relatives, or red, as in the Many-coloured Rush-tyrant. A few have a conspicuously shaped, bushy or flattened crest or "helmet", a distinctive feature of, among others, the Royal Flycatcher and the Helmeted Pygmy-tyrant (*Lophotriccus galeatus*). In all these cases, display behaviour regularly includes raising of the crown feathers vertically and somewhat laterally, exposing the colourful mid-crown patch, while facing the other individual, and is usually accompanied by active vocalizing and often by raising, spreading, fanning or fluttering of the wings. Some species engage in complex vocal duets during such displays (see Voice).

Perhaps the most amazing performance is that of the Royal Flycatcher. This species erects its crest feathers into a full semi-circle around the head, opens its bill wide to reveal a bright orange mouth-lining, and rotates its head about the axis of the neck, alternately in one direction and then in the other, in a very deliberate mechanical fashion, as if it were a wind-up toy. Presumably, this display is associated with courtship, territorial encounters or anti-predator behaviour, but few biologists have seen the display under natural conditions. Virtually all observations of the Royal Flycatcher with its crest raised have been by amazed biologists as they remove this species from the mist-net.

Species in the genera *Leptopogon*, *Mionectes* and *Pogonotriccus* have a peculiar habit of rapidly raising and lowering one

Here we are offered a rare glimpse into the private life of a widespread but easily overlooked species. An adult ***White-throated Spadebill****, a tiny sprite of the dark forest understorey, is about to feed a spider to its brood. Nest architecture is quite distinctive in this species: it builds a deep cup out of dry bamboo leaves and fine fibres, including, where available, the dark hyphae of "horsehair fungus"* (Marasmius). *It wraps this structure with spiders' webs, both to keep it firm, and to ensure a secure attachment to the supporting branches. The choice of prey is not surprising given the usual foraging mode adopted by this species: it is an expert at sally-striking to the underside of leaves. Also nicely revealed here are the characteristic short tail, large eyes, substantial rictal bristles and shovel-shaped bill.*

[*Platyrinchus mystaceus neglectus*, Monteverde Forest Reserve, Costa Rica. Photo: Michael & Patricia Fogden]

or, more rarely, both wings while foraging. The raised, open wing is held only momentarily in a vertical position high over the back, and is then snapped back into place as if it were a mechanical toy. This odd display can occur repeatedly every few seconds, and often takes place in the absence of conspecifics. Its function is unknown.

Numerous tyrant-flycatchers actively mob potential avian predators such as crows (Corvidae), hawks (Accipitridae) and owls (Strigiformes). In open country across North America, a common sight during the summer months is that of up to three or four Eastern Kingbirds closely pursuing an American Crow (*Corvus brachyrhynchos*) across a field, calling actively over the corvid and periodically diving at it and striking it with the bill. In tropical latitudes, the Great Kiskadee and the Social Flycatcher regularly mob and attack potential nest predators, including capuchin monkeys (*Cebus*), toucans and araçaris, hawks and falcons, and snakes. In one instance, a Great Kiskadee was observed as it vigorously attacked a Collared Forest-falcon (*Micrastur semitorquatus*), during which it rode on the falcon's back for several seconds. Phoebes, many species of *Myiarchus*, the two beardless tyrannulets, *Elaenia* species, the Vermilion Flycatcher and a good number of other tyrannids often participate in multiple-species mobbing aggregations, attracted by the predators themselves or by avian alarm calls.

The alarm response of a tyrant-flycatcher to snakes with aposematic coloration, such as coral snakes (Elaphidae), has been shown by S. M. Smith to be a genetically inherited trait. Smith raised young Great Kiskadees in isolation, prohibiting any contact with adult kiskadees or other birds. When she exposed these naive kiskadees to uniformly coloured wooden dowels, the birds showed no interest. When the dowels were painted with ring patterns typical of poisonous coral snakes, however, the kiskadees retreated to the far end of the cage and uttered scolding calls.

Anting behaviour has been reported for a variety of tyrant-flycatchers in all three of the typical subfamilies. The function of this peculiar behaviour, which involves the rubbing of the feathers of the belly, underwing and tail with the mutilated body of an ant held at the bill tip, remains unknown. As ants appear in the diets of many tyrannids (see Food and Feeding), the behaviour may serve in part as a means of reducing the amount of chemical defence, such as formic acid, in the body of an ant before its consumption.

Voice

With few exceptions, tyrant-flycatchers are vocally undistinguished. They share with the other suboscine passerines a relatively simple syrinx, lacking the more elaborate vocal apparatus of the oscine songbirds. All suboscines generally utter simple phrases, chirps or trills, many of which sound unmusical. In general, the daytime songs of tyrant-flycatchers are higher-pitched and significantly more variable than are the monotonous series of ascending or descending whistles and clucks typical of the furnariids, the dendrocolaptids, the antbirds and the tapaculos. Tyrannid songs consist mostly of one or a few whistled, warbled or modulated notes. Sometimes these are arranged into phrases or trills, but rarely do they have a complicated pattern and hardly ever would they be described as beautiful. It bears emphasis, however, that even the simple songs of tyrant-flycatchers are crucial species-specific isolating mechanisms, many of which allow clear differentiation, both by the birds themselves and by human observers, between what are otherwise exceedingly similar and closely related species. As with the other suboscine groups, it is generally assumed that the vocalizations of tyrant-flycatchers are entirely innate, although rather little research has been done to prove or refute this hypothesis.

Vocal qualities vary considerably among tyrannid groups. Insignificant, variably twittering peeps and trills are offered by many of the smaller species in the Elaeniinae, such as members of the genera *Phyllomyias*, *Zimmerius*, *Pogonotriccus* and *Phylloscartes*. Soft whistles, given singly or in ascending series, characterize most flatbills in the genera *Tolmomyias* and *Rhynchocyclus*. The *Elaenia* and *Myiopagis* elaenias typically utter a single, short, melodic phrase, examples being the burry "wher-cheeeer" of the Mottle-backed Elaenia (*Elaenia gigas*) and the soft "pil-dooeet" of the Forest Elaenia (*Myiopagis gaimardii*). Most fluvicolines have slightly louder and more recognizable primary songs. The "pee-o-weeee" song of the Eastern Wood-pewee is quite different from the high, burry "pt-cheeeeer" of its close relative, the Western Wood-pewee, and the ringing "quick-three-beers" of the largest pewee, the Olive-sided Flycatcher.

By far the most vocally raucous of all tyrant-flycatchers is the Great Kiskadee. Its harsh, loud "kis-ka-dee!" calls are often shouted boldly and repeatedly by both members of the pair in

*The nest of the **Many-coloured Rush-tyrant** is a tiny cone-shaped cup, a bit like an ice-cream cone attached to a single reed stalk, and the outer surface of the nest is coated with a strange gum. The female constructs the cup alone, using wet material which dries and hardens to form a cardboard-like crust. This rigidity helps to maintain the shape of the nest despite the constant movement of the swaying stem to which it is attached. This image shows how the species earned its local name of "Siete Colores", or seven colours. The dramatic red crest is often invisible in the field, but is flared conspicuously during aggressive interactions and courtship display, especially around the nest.*

[*Tachuris rubrigastra rubrigastra*, Provincia de Cardenal Caro, Cahuil, Chile. Photo: Manuel Marín]

*The **Cliff Flycatcher** is one of few tyrannids that habitually nest on rock faces. It commences the nest-building process by building a ring of stones on a ledge, which helps to increase stability once the nest is built. The nest itself is an untidy cup of plant fibres and grasses. Because of its cliff-nesting habits, the Cliff Flycatcher is pre-adapted to man-made structures, such as bridges and buildings. In some cities, such as São Paulo, it has learnt to nest on blocks of flats and commercial high-rises.*

[*Hirundinea ferruginea sclateri*,
La Trampa, Táchira,
Venezuela.
Photo: Peter Boesman]

territorial declaration as they perch together atop a tall tree. In their most animated sequences, both pair-members alternately raise and lower the wings stiffly above the back in time with the loud calling. The same birds often intersperse their "kis-ka-dee" displays with a single, long phrase of similar quality, "keeeeeeeerrrrr".

Pygmy-tyrants and tody-tyrants share a distinctive vocal quality unlike that of any other flycatcher group. They utter mechanical "pip" notes, some metallic and others quite nasal, and often as a rapid series or trill. These notes may ascend the scale in a series of separately uttered, piping notes, as in the case of, among others, the Black-throated Tody-tyrant. Alternatively, they may remain at the same pitch in a rapid trill, such as that given in the Central American and Andean montane forests by the Scale-crested Pygmy-tyrant, the distinctive voice of which sounds like a police whistle. In complete contrast, the short, extremely high-pitched trill of the Short-tailed Pygmy-tyrant cannot easily be separated from insect sounds in the tropical forest.

Although the Sirystes can be difficult to see, as it spends almost the entire time in the highest part of the forest canopy, its distinctive call enables the observer to locate it. This species' ringing "wher-péw…wher-péw-péw-péw-péw" can be heard from the human vantage point on the forest floor up to a kilometre away.

The Ochre-bellied Flycatcher is silent over most of the year, but certain males take up and defend calling stations within the forest during the breeding season. Within these small areas, measuring 100-750 m² in extent, individual males perch usually at heights of 3-10 m and call incessantly, throughout the day, for weeks and even months on end. The typical call at these leks (see Breeding) is a deliberately paced series of paired, piping notes, "whip whit, whip whit", repeated up to ten times, followed by a more animated series of "chit" notes in more rapid succession.

In addition to primary, daytime advertising songs, the majority of tyrant-flycatchers also produce very simple, single-note or double-note contact vocalizations, or position-calls, that are species-specific. Most of these are short "chip" or "peep" notes of varying pitch, intensity and timbre. Some are uttered apparently as contact notes between members of a pair or within a mixed-species flock, whereas others are given each time a foraging flycatcher changes its perch.

A number of tyrannids, especially in the subfamily Fluvicolinae, sing elaborate, even melodious songs in conjunction with courtship or territorial displays (see Breeding). A well-studied example is that of the Vermilion Flycatcher, the male of which sings a long jumbled series of sweet whistles and warbles during its long display-flights over open fields. The Streamer-tailed Tyrant, on the other hand, displays from a perch, where piercing whistles, warbles and bill-popping sounds are made in a mutual display between male and female.

Most pygmy-tyrants and tody-tyrants sometimes produce audible wing-whirring sounds when moving from perch to perch. In addition, a few species engage in rapid wing-flapping displays from a perch, during which the wings produce a mechanical buzzing or whirring sound. The feathers of some of these species, such as the Pale-eyed Pygmy-tyrant, are modified to aid in this sound production (see Morphological Aspects). The complex advertising songs of the doraditos in the genus *Pseudocolopteryx* include bill-snapping and wing-buzzing. Males of the Crested Doradito engage in dramatic displays associated with these songs, given both on the perch and in the air (see Breeding). As mentioned previously (see Morphological Aspects), males of this species have modified primaries and barbules, both features apparently playing a role in the peculiar wing-buzzing component of the aerial display.

The most distinctive feature in the vocal repertoire of tyrant-flycatchers is the dawn song, which is generally lacking in the other groups of suboscine passerines. The dawn song is uttered by a perched, otherwise motionless individual during a "waking-up" period of 10-30 minutes, beginning just as the very first light of dawn appears, and well before most other birds begin to vocalize. These dawn songs in general are short, ringing phrases repeated over and over again, incessantly, while the bird remains on a single perch. They sometimes contain components of, or slight variations on, the more typical advertising songs that are uttered individually throughout the day. Quite often, however, the dawn song is utterly distinct from the daytime song and, except on rare occasions, is not delivered at any time other than during first light of dawn or, more rarely, at last twilight. The phenomenon characterizes tyrant-flycatchers as far north as eastern North America, where in mid-June, at the first hint of dawn's light, one can hear simultaneously Eastern

*The **White-headed Marsh-tyrant** builds a globe-shaped structure of dry grasses and feathers. It usually attaches this messy ball to several reeds, or to the branches of a small aquatic shrub. As this nest is such a conspicuous bundle, it is difficult to hide from predators, but the ball-shaped nest has a very small entrance and is almost always placed over standing water. These strategies serve to minimize opportunities for mammalian predators to raid the nest.*

[*Arundinicola leucocephala*, Esteros del Iberá, Corrientes, Argentina. Photo: Hernán Povedano]

Wood-pewees, Alder and Willow Flycatchers, Great Crested Flycatchers and Eastern Kingbirds as they repeat their songs rapidly and ceaselessly, for many minutes on end. In western and south-western North America, Cassin's Kingbirds and Vermilion Flycatchers are strong dawn singers. Farther south, in the mountains of Central America, the little Tufted Flycatcher, the daytime song of which is a simple series of weak whistles, utters at daybreak, ceaselessly for 20-30 minutes, a remarkable refrain of sweet, rapidly jumbled notes from a high, exposed perch; A. F. Skutch transcribed a piece of one such bout as "bip-bip-bip-dididididup-bip-bip-bibibiseer". The dawn song becomes a most remarkable chorus in the tropics, where in the earliest moments of dawn, in a South American scrub or lakeshore setting, the human observer can hear the endlessly repeated songs of 15 or more species of flycatcher, the very first birds to begin singing.

Almost all tyrant-flycatchers, from the smallest tyrannulets to the largest kingbirds and their relatives, utter distinct dawn songs. These are so stereotyped and so species-specific that a major taxonomic revision of the genus *Myiarchus* included a key to the species based solely on the acoustic features of their respective dawn songs. Moreover, several newly discovered tyrannid species have been first detected by astute field observers who heard unfamiliar dawn songs (see Systematics).

Food and Feeding

As the family name at least casually implies, by far the predominant food resources for tyrant-flycatchers of every taxonomic group are insects and other arthropods, the latter including, for example, arachnids, millipedes (Diplopoda) and centipedes (Chilopoda). Small fruits are the second most common food category, and small vertebrates such as tree-frogs, tadpoles, lizards, small snakes and fish are taken by a limited number of larger tyrannids. The members of this family employ an enormous variety of searching and prey-capture techniques, but they invariably capture and deal with all food items by using the bill.

Extensive studies of the stomach contents of 16 sympatric tyrant-flycatchers in Costa Rica, carried out by T. Sherry, and of those of 28 sympatric species in the Amazonian lowlands of south-eastern Peru, undertaken by A. Begazo, exemplify the diversity of prey items consumed by tyrant-flycatchers, and illustrate a few patterns of specialization. Stomachs of all but one species in Costa Rica and all but two in Peru contained beetles of numerous different families. The Ruddy-tailed Flycatcher was an exception in both studies, taking almost exclusively fulgoroid homopterans, and the other exception in Peru was the Short-crested Flycatcher, which fed predominantly on ants and wasps (Hymenoptera), assassin or stink bugs (Reduviidae) and cicadas (Cicadidae). The majority of species in the studies also consumed, in addition to beetles, combinations of numerous ants and wasps, spiders (Arachnida), cicadas and leafhoppers (Homoptera), and lepidopteran larvae. Also represented were a variety of scorpions (Scorpiones), dragonflies (Odonata), katydids and crickets (Orthoptera), flies (Diptera), true bugs (Heteroptera) and earwigs (Dermaptera). Prey sizes ranged from tiny, such as unidentified arthropod eggs and small ants, to several centimetres in length, such as dragonflies, cicadas, small frogs and small lizards. In both regions, aerial salliers were prone to take flying ants, wasps and bees. The diets of species that forage in the densest vegetation tended to be higher in beetles, spiders, planthoppers and non-flying ants. Seven of the 16 species in Costa Rica had consumed fruit, but corresponding data were not reported for the Peruvian site.

The ecological diversity of tyrant-flycatchers as a family is manifested most clearly in the range of foraging styles and associated habitat preferences found across its different evolutionary assemblages. Almost all tyrannids search for food by using some modification of a single basic procedure, the search-and-sally technique, in which an individual pauses for varying lengths of time on a perch or on the ground, and then either moves quickly after a prey item or gives up the position and moves to a new one. Active, exploratory types of behaviour, such as probing, tearing, gaping, leaf-scratching and the searching of dead leaves, or other active food-seeking methods, are extremely rare among the Tyrannidae. For the most part, therefore, foraging by tyrant-flycatchers is a visual searching procedure. A large part of the variation in searching strategies involves the amount of time for which a flycatcher typically pauses before either sallying or "giving up". Over the family as a whole, these search times vary approximately with body size, but sally technique and the density of

vegetation cover also play a role in determining the pace of movement of an actively foraging tyrannid.

Prey capture is accomplished by a variety of manoeuvres, mostly quite stereotyped, and these movements are closely associated with specific morphological adaptations of the bill, wing and tarsus (see Morphological Aspects). Aerial hawking is the foraging method that many birdwatchers know as "typical" flycatcher behaviour. The foraging bird sits relatively motionless on an exposed perch, with the head moving rapidly from side to side and up at sharp angles as it searches for, and often tracks, flying prey. The sally is a rapid flight directly out to snatch the insect in mid-air with the bill tip, often making an audible snap as the mandibles close on the prey. Aerial hawkers are patient foragers, sometimes sitting on the same perch for minutes on end before sallying or, if necessary, moving to a new perch. Species that habitually use this foraging mode, such as the Cinnamon and Cliff Flycatchers and those in the genera *Contopus*, *Mitrephanes*, *Empidonomus*, *Griseotyrannus* and *Tyrannus*, regularly return again and again to the same spot in order to search for prey. Typically, the Cliff Flycatcher, even after unsuccessful sallies, returns to its cliff-face site to resume searching from a perch, but occasionally it engages in extended, acrobatic and even multiple pursuits of aerial prey. Various studies have demonstrated that aerial hawkers tend to gauge the relative value of a perch very carefully, staying at the perch if it regularly produces prey and abandoning it if it does not. Indeed, it has been shown that the longer an individual had to wait before making a sally, the less was its tendency to return to the same perch to resume searching.

The commonest prey items for aerial-hawking tyrant-flycatchers are large flying insects. Eastern Kingbirds, for instance, frequently perch near the hives of honeybees (*Apis*) in order to sally after the flying insects; it is said that they favour the slightly heavier-bodied males, or drones, over the faster-flying female bees. An exhaustive survey of the stomach contents of Eastern Wood-pewees revealed that about 30% were hymenopterans and 30% dipterans, with 12% lepidopterans and 10% coleopterans. In a study of this species in its non-breeding quarters in south-eastern Peru, 92% of the contents of stomachs consisted of Hymenoptera. At the latter site, 68% of 94 prey items of Tropical Kingbirds were hymenopterans and a further 20% were flying termites (Isoptera). At study sites in both Costa Rica and Peru, the Long-tailed Tyrant, an obligate aerial hawker, also took mainly hymenopterans, which at the former site consisted almost exclusively of stingless sweatbees of the genus *Trigona*. Sherry hypothesized that this flycatcher preferentially forages near *Trigona* nests.

Although almost every member of the family occasionally engages in aerial hawking, most species are not obligate hawkers but can be referred to, instead, as "sally-gleaners". In this method of foraging, the individual flies with a rapid sally from its perch towards a prey item that is sitting on some substrate, such as a leaf, a twig, a trunk, a rock or the ground. The item is picked or snatched from the substrate, not from the air. Foraging sally-gleaners pause at each perch in order to search the surroundings, including twigs, vegetation, trunks, the ground and any nearby water, and may only rarely snatch flying prey on the wing. There are several common forms of sally-gleaning that lead to quite different morphological and behavioural specializations, as outlined in the following few paragraphs.

Hover-gleaners typically perch in small openings within vegetation, or on exposed perches overlooking it, and cock the head at all angles, enabling them to examine the leaf surfaces for prey. They make rapid sallies towards prey, but usually snatch the food from the leaf surface during a brief to extended, stationary hover. *Leptopogon* flycatchers, such as the Sepia-capped Flycatcher (*Leptopogon amaurocephalus*), and the true bristle-tyrants, typified by the Spectacled Bristle-tyrant, usually perch on exposed twigs under vegetation and sally upwards to snatch prey with an upward-directed hover-glean, the body held almost vertically below the prey. These tyrannids have a long and cylindrical bill with a slight hook, similar to the bill of many vireos, another family that often hover-gleans. The *Myiarchus* flycatchers, along with the related Sirystes and Rufous Casiornis (*Casiornis rufus*), typically perch more in the open, overlooking dense vegetation, where they make outward or downward bobbing movements of the head to peer at odd angles in characteristic searching behaviour that can last for up to a minute at each perch. They sally outwards or downwards to snatch prey, often lepidopteran larvae, with a brief hover-glean, frequently slowing down only slightly and crashing into the vegetation, with a follow-up flight that carries them through to a new perch. Often they make an audible snap as they grab the food item. Hover-gleaners rarely

Anyone looking at this photo might be forgiven for concluding that the ***Cattle Tyrant*** *builds an enormous nest out of sticks, a highly unusual construction for a tyrant-flycatcher. As it happens, the tyrant's nest is relatively small, but is often sited opportunistically, and this bird has appropriated the abandoned nest of a Greater Thornbird* (Phacellodomus ruber). *The furnariid usually navigates a funnel at the base of its monstrous residence, but this nest has collapsed on one side, allowing the tyrant to build its cup-nest in a protected spot. Most Cattle Tyrant nests are located in secluded recesses, such as deep within branching palm fronds.*

[*Machetornis rixosa rixosa*, Minas Gerais, Brazil. Photo: Anita Studer]

Some members of the genus Tolmomyias *build an unusual nest rather like that of an icterid. It is typically constructed with black fungal hyphae and rootlets, and is shaped like a retort flask, with a tunnel entrance angled downwards. In some regions, the majority of nests are placed in the vicinity of colinies of wasps* (Chartergus, Polybia, Polistes)*, a defensive measure against predation. This* ***Yellow-olive Flycatcher*** *is far more likely to raise a brood with a horde of stinging insects guarding her nest. Once the nest is completed, the owner rarely clings to the outside, but usually flies directly in and out of the nest entrance.*

[*Tolmomyias sulphurescens cinereiceps*, Santa Rosa National Park, Costa Rica. Photo: Marie Read]

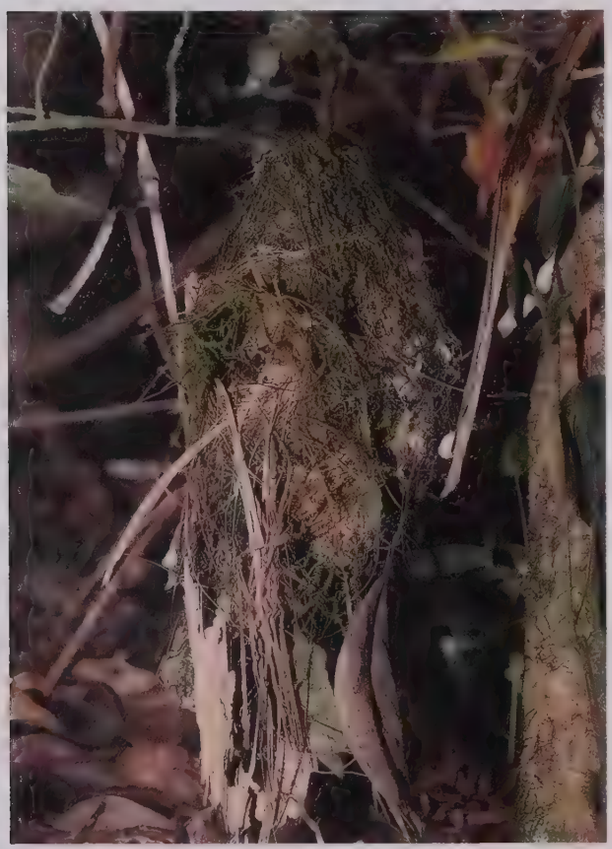
return to the same perch after a sally, but keep moving as if traplining through the foraging territory. An extensive study of the diet of one *Myiarchus* species, the Great Crested Flycatcher, across eastern North America revealed that the stomach contents consisted of 21% lepidopterans, 17% coleopterans, 16% orthopterans, 14% hemipteran bugs and 14% hymenopterans.

The upward strike is a highly stereotyped form of sally-gleaning in which prey is snapped or "scooped" from the undersurfaces of leaves during a rapid upward flight, or strike, directly from below. Tyrannids that practise this foraging style most frequently, such as the widespread White-throated Spadebill in the genus *Platyrinchus* and the tody-flycatchers in the genus *Todirostrum*, usually pause on each perch for 15-45 seconds before either giving up or sallying. Invariably, they search upwards from each perch. Specialists in this foraging mode have a distinctively broad, even shovel-shaped, bill and well-developed rictal bristles. Dietary studies of upward strikers, including the two aforementioned genera and members of *Tolmomyias*, *Hemitriccus* and *Lophotriccus*, demonstrate that they take a broad diversity of arthropods, with beetles, especially weevils (Curculionidae), and planthoppers (Fulgoroidea), bugs, lepidopteran larvae and spiders predominating.

Of particular interest is the Ruddy-tailed Flycatcher. This species employs an unusual foraging method termed "flush-chasing", in which the bird dislodges prey from a leaf or twig with a quick sally, and then rapidly and erratically chases it downwards and through the forest for up to several seconds. In Costa Rica, Sherry discovered that the Ruddy-tailed Flycatcher uses this unique foraging manoeuvre to feed almost exclusively on homopteran bugs, especially leafhoppers and planthoppers, which accounted for 46 of 65 prey items recorded. The same has now been shown for this species in the Amazon forest of south-eastern Peru, where 45 of 47 documented prey items were fulgoroids. Few other groups of foliage-gleaning birds are so restricted to just a single taxon of insects.

Another common method for gleaning prey from the vegetation is perch-gleaning, which involves no sallying at all. Many warblers and vireos also forage in this manner, and it is not surprising that those tyrant-flycatchers that use this style extensively tend to be small, active warbler-like birds with a thin, needle-like or tweezer-like bill. The foraging individual searches leafy vegetation, examining leaf surfaces and peering into folds and cracks at extremely close range, during very brief pauses of typically only one or two seconds in duration. Prey such as spiders, small lepidopteran larvae, beetles and ants are simply picked from the substrate within the reach of the foraging bird. Most perch-gleaners are in the subfamily Elaeniinae, and include, among others, the Northern Beardless Tyrannulet and the White-crested Tyrannulet (*Serpophaga subcristata*).

Terrestrial foraging is uncommon in the Tyrannidae, but it has evolved independently within several lineages. Most of the prey-capture techniques used by arboreal flycatchers are found also among terrestrial ones. An intriguing example is represented by the two species in the genus *Corythopis*, the Ringed and Southern Antpipits. These are entirely ground-walking tyrannids inhabiting moist tropical forests, where they walk deliberately across the leaf litter of the forest floor, but they search for prey mainly by looking upwards. They capture a wide variety of prey items from the underside of ground-storey vegetation, just a few centimetres above them, by means of upward strikes. A study of stomach contents of Ringed Antpipit specimens from south-east Peru revealed that, of 61 prey items identified, flower beetles constituted 21%, click beetles (Elateridae) 10% and weevils 3%, with ants making up 20%, wasps 7%, spiders 3% and scorpions each 3%, planthoppers 5%, cicadas 3%, katydids 2%, and lepidopteran larvae and pupae 10%; even small frogs were found, accounting for 3% of recorded items.



A large radiation of genera in the Fluvicolinae, occupying open habitats of eastern and southern South America and the high Andes, displays a graded series of ground-oriented foraging techniques. The first stage is perch-to-ground foraging, in which individuals perch on elevated rocks, branches, fence posts, wires or rooftops and search the ground below for insects or small vertebrates. Perch-to-ground specialists sally to the ground, capture a prey item, and return to the elevated perch to devour it and to resume searching. Many species simply snatch an insect from the surface and return to the perch without stopping, but some may alight on the ground and deal with the prey there. The *Xolmis* monjitas of the open habitats in Brazil, Uruguay, Paraguay and Argentina are advanced perch-to-ground specialists, as are the large, shrike-like predators in *Myiotheretes*, *Agriornis* and related genera inhabiting the high Andes and Patagonia. These species take especially big prey, such

Some of the most elaborate of tyrannid nests are made by small species inhabiting the forest understorey. The nest of the ***Ochre-faced Tody-flycatcher*** *is a typical example. It is a purse-shaped structure, suspended by plant fibres from a twig. It has a concealed side entrance, often protected by a "visor", and it is usually lined with very fine downy material, such as seed down and feathers. This species, like many others in the family, sometimes places its nest near active nests of paper wasps* (Polistes)*, which are armed with a vicious sting.*

[*Poecilotriccus plumbeiceps*, Alagoas, Brazil. Photo: Anita Studer]

as large beetles, grasshoppers, moth larvae, and even lizards and snakes. The most advanced terrestrial foragers in this radiation accomplish most or all of their prey-searching while standing on the ground, where they make fast runs or quick sallies to capture food items from the ground surface or low vegetation. Terrestrial specialists of this type include most of the *Muscisaxicola* ground-tyrants and the sole member of the genus *Neoxolmis*, the Chocolate-vented Tyrant, which is the largest.

To the untrained eye, and to many potential predators, there is nothing to be seen in a scene like this but a tangle of debris in the understorey. By cleverly incorporating flakes of bark, dead leaves, moss and any material that helps give the impression of random detritus hanging in the understorey, the ***Eye-ringed Tody-tyrant*** *conceals her nest from predators. Accessible though a side entrance, just visible here, is the downy cup where she will lay her eggs. Nests of this type are extremely difficult to locate unless the female is seen entering or leaving.*

[*Hemitriccus orbitatus*, Serra da Cantareira State Park, Guarulhos, São Paulo, Brazil. Photo: Dante Buzzetti]

Rufous-webbed Bush-tyrants are perch-to-ground specialists that, in the incessant high-Andean wind, also frequently hover or glide with the wings high over the head as they search for, or get a bearing on, prey amid the rocks and tussock grass above the tree-line. Similarly, the Dark-faced Ground-tyrant (*Muscisaxicola maclovianus*), although typically a pipit-like ground-forager, will often hover over open areas for long periods, with its tail spread wide, as it watches for potential prey items from mid-air; it then flutters or parachutes down and, just as it lands, snatches an insect.

The Great Kiskadee is probably the most omnivorous of all tyrant-flycatchers. A widespread and relatively common species in open habitats throughout the tropical Americas, the kiskadee frequently takes advantage of whatever local source of large food items it can find, including fish, lizards, frogs, tadpoles, baby birds, all manner of fleshy fruits, millipedes, large beetles, carrion, and even garbage from a rural back yard or the town dump. This species is very often found near water, where it hunts in a fashion very similar to that of kingfishers (Alcedinidae); the kiskadee plunges from a low perch to pick a fish or tadpole from the water, flies to a nearby perch, and beats the prey back and forth on the branch until it can be swallowed. One Great Kiskadee in eastern Brazil was timed as it beat a 5-cm cichlid fish for 13·5 minutes before swallowing it. Kiskadees sometimes even hover over a large waterbody like a kingfisher in order to spot a tadpole, which they pluck with a quick dive.

Many of the largest-bodied tyrant-flycatchers prey on vertebrates, especially frogs and lizards. The Great Shrike-tyrant of Chile and southern Argentina occasionally preys on fledglings of other bird species, and has been observed to capture and kill a medium-sized hummingbird, a Green-backed Firecrown (*Sephanoides sephaniodes*), that was feeding in a mistletoe patch. The largest of all tyrant-flycatchers, it has also been recorded as preying on the high-Andean long-haired mouse (*Akodon longipilis*). Many of the larger bush-tyrants and ground-tyrants frequently capture terrestrial lizards on the run. All seven species in the genus *Attila* have a sharply hooked bill and regularly attack and subdue very large prey, including large spiders, huge noxious caterpillars, large beetles, arboreal lizards and snakes, and frogs. Four of 13 prey items in the stomachs of Bright-rumped Attilas were arboreal lizards. Similarly, the Boat-billed Flycatcher,

which lives high in trees, uses its massive bill to snatch very large prey items, ranging in size from moths and beetles up to arboreal snakes and lizards, from the undersides of leaves.

Frugivory is widespread among all groups of tyrant-flycatchers, and almost every species in the family will consume an occasional ripe fig, mistletoe berry, melastome fruit or *Cecropia* fruit, or a small, pulpy drupe, such as a fruit of Lauraceae or Anonaceae, high in the forest canopy. Fruit forms a significant proportion of the diet throughout the year for many species in the subfamily Elaeniinae, especially those in the genera *Phyllomyias*, *Phaeomyias*, *Myiopagis*, *Elaenia*, *Mionectes* and *Zimmerius*. The Paltry Tyrannulet (*Zimmerius vilissimus*) is virtually a specialist on mistletoe berries, and consumes hundreds of these each day over much of the year. Its habit of regurgitating the sticky seeds by wiping them off on the perch is a principal means by which the mistletoes are dispersed throughout the mid-montane forests of Central and northern South America. Nearly obligate, year-round frugivory by members of the genus *Mionectes* provides the evolutionary backdrop for their lekking social system (see Breeding), which is unique among the Tyrannidae.

Almost all species in the subfamily Tyranninae are to one degree or another frugivorous in all months of the year, and a few of them rely on fruit as a primary resource every day. The Piratic Flycatcher in the monotypic genus *Legatus* is the most pronounced fruit-eater, but its close relatives in the genera *Myiodynastes*, *Myiozetetes* and *Conopias* eat fruits all year as well. Several members of this assemblage, such as the Social Flycatcher and the Great Kiskadee, are known to feed their young with pulpy fruits, along with insects, especially near the end of the nestling period.

Finally, the Sharp-tailed Tyrant, an elaeniine tyrannid, is possibly distinct from all other members of the family in one particular aspect of its diet. Field observations suggest that this grassland-inhabiting species feeds not only on insects, but also on the seeds of grasses and weed plants.

Breeding

All tyrant-flycatchers in North and Central America breed during the northern spring and summer, mainly between March and July. In the southern USA, breeding by Eastern Kingbirds, Great Crested Flycatchers and Black Phoebes begins as early as mid-March. Species that breed high in the mountains, such as the Dusky Flycatcher, or in the northern USA and Canada, such as the Olive-sided Flycatcher, generally do not start to nest until early May. In the lowlands of northern South America and in the Andes north of central Peru, most breeding takes place from January to June. Farther south, in the southern Andes and the lowlands south of the equator, the breeding season of virtually all tyrannids spans the period from August through to January. Typically, the members of this family raise only a single brood of young each year.

The predominant social system of tyrant-flycatchers, in both temperate and tropical latitudes, is the monogamous pair-bond, with each pair defending its own territory. Monogamous social organization does not, however, guarantee genetic monogamy. In the USA, genetic examinations for extra-pair paternity in the Eastern Kingbird in central New York State revealed that 60% of nests contained young sired by a male other than the territory-holder. Of 64 nestlings genetically profiled, 42% were sired by extra-pair males, but conspecific brood parasitism was absent. By contrast, in a separate study of the same species, in Michigan, 39% of nestlings were unrelated to either one or both parents, and conspecific brood parasitism was implicated in most of these cases.

Species in the genus *Mionectes* are the only tyrant-flycatchers known to exhibit lek behaviour, and the social systems of several of these species have been studied in detail by D. W. Snow, E. O. Willis and, especially, D. Westcott. One of them, the Ochre-bellied Flycatcher, is the most abundant forest tyrannid in many lowland habitats throughout South America. Its abundance is probably related to the fact that it is highly frugivorous, perhaps more so than any other member of the family. Females are capable of regurgitating large quantities of fruit pulp with which to feed the young, thereby emancipating males from nest duties, a prerequisite for lek breeding systems. Females usually construct their hanging, oven-shaped nests over streams inside the forest, and do not establish pair-bonds with any particular male. Instead, throughout the breeding season, some males sing and display within a loosely defined area, the lek, in which two to six individuals are within earshot, but not visual range, of one another. Other males display solitarily, and still others, about 10%

*The **Sepia-capped Flycatcher** sometimes works for more than a month to construct its distinctive pendent nest. It builds a compact oval, often camouflaged with a variety of live moss and debris, and sometimes appended by a hanging "tail" of similar material. These nests often dangle from bare roots where banks have been undercut, as shown here. For this reason, a lucky walk along a forested creek may result in one of these structures being encountered, usually hanging at head height. Their love of overhangs also means that* Leptopogon *flycatchers regularly nest under the eaves of buildings situated in forested habitats.*

[*Leptopogon amaurocephalus amaurocephalus*, Minas Gerais, Brazil. Photo: Anita Studer]

The nests of Mionectes *are quite similar to those of* Leptopogon *in structure. They are a hanging ball of moss and debris, but they are distinctly smaller, less often situated at overhangs, and more often out of reach over wider streams. Although the sexes are virtually indistinguishable in this genus, this* ***Grey-hooded Flycatcher*** *is almost certainly a female because, unlike all other tyrant-flycatchers,* Mionectes *are obligate year-round frugivores with a breeding system remarkably similar to manakins (Pipridae). Males occupy positions at leks and females take sole responsibility for raising the brood. Thus, no male is ever likely to be seen attending a nest.*

[*Mionectes rufiventris*, Minas Gerais, Brazil. Photo: Anita Studer]

in one study, behave as subordinate "satellites" on the territories of displaying males, and may eventually replace the owner of a display territory. Finally, about half of the males are not associated with a display territory at all; these behave as "floaters" and move widely through the forest, often intruding on displaying males' territories. Aggression among males, especially by those holding display territories, is very common. Females visit the lekking males, and the male with the highest visitation rate and, presumably, the highest copulation rate tends to be in the largest lek and tends also to have the highest song rate. In one study, experimentally muted males suffered far greater levels of intrusion by other males than did non-muted ones, and five of six experimental males quickly lost their territories to intruders. Thus, song plays a key role in interactions between males at leks, and is also used by females as a means of assessing potential mates. The locations of leks in the forest are correlated with travel routes regularly used by females.

The peculiar tail feathers and aerial displays of both species in the genus *Alectrurus*, the Cock-tailed and Strange-tailed Tyrants, strongly suggest a polygynous mating system in which sexual selection has produced extreme sexual dimorphism, including male ornamentation. Indeed, preliminary studies in the field bear out this possibility. Males of both species appear to defend territories in grassland and grassy marsh habitats, where they perform striking display-flights over females in the grass or reeds below. Observations have revealed that some territories contain several females. Further fieldwork may well produce some interesting findings with regard to these two unusual tyrannids.

The most elaborate displays in the family are those of the sexually dimorphic, fluvicoline species that inhabit scrub, grassland and marshes in southern Brazil, northern Argentina, the Paraguayan Chaco and the high Andes. Strangest of all is that of the Spectacled Tyrant, the spectacular aerial courtship display of which was first described, with wonderful imagery, by Hudson in 1920. The all-black males "perch on a conspicuous place, upright, motionless, and looking more like grotesque little automata than living things"; the displaying male, "as if shot from [the perch] by means of a steel spring... darts vertically to a height of about fifteen yards, then turns a somersault, uttering at the same moment a shrill little cry, after which it drops down again and alights on its perch suddenly, as if jerked back to it". During the descent, the wings of the Spectacled Tyrant are held stiffly half-open, showing the white patches, and the vibrating primaries produce a rattling or buzzing sound.

Almost as striking is the display given by another fluvicoline, the Andean Black-tyrant (*Knipolegus signatus*), in which the male repeatedly flies straight up into the air for 2-10 m, and then drops straight back down with the wings folded, spreading them immediately before crashing to the perch. Its congeners mostly perform fairly similar displays. For example, the White-winged Black-tyrant (*Knipolegus aterrimus*) repeatedly makes a short flight up, stalls with the body and tail pointing vertically downwards, then topples backwards before pulling out of its dive to return to its perch, sometimes emiting a faint vocalization. The ground-tyrants also perform elaborate aerial displays during the breeding season. The male Rufous-naped Ground-tyrant (*Muscisaxicola rufivertex*), for example, flies up to 10-15 m above the open ground and hovers or hangs in the wind, with the wings high over the back, uttering a thin two-note whistle. Dark-faced Ground-tyrant males, on the other hand, stand upright near a female and raise and lower the wings, or raise the wings and hold them high overhead for up to 10 seconds, before making a short run and repeating the display. During the breeding season, the male Vermilion Flycatcher launches into long aerial flights over open fields; in these displays, which are accompanied by the pleasing song (see Voice), the bird often holds its wings up over the back, producing the appearance of a fluttering butterfly.

Mutual displays between the two sexes are a feature of some tyrannids, of which the Streamer-tailed Tyrant is one example. Sitting close to each other on the top of the same low shrub, or an adjacent one, the male and female bob up and down on a perch, flap the wings, and alternately raise and lower the long tail, while uttering loud calls (see Voice). Deliberate wing-flapping is a common element in displays throughout the family, and is often performed in conjunction with vociferous calling and crest-displaying. Some species, such as the *Ochthoeca* chat-tyrants and the *Fluvicola* water-tyrants, at times exaggerate this wing-flapping by holding the wings outstretched or flapping them broadly and stiffly while perched. Others flutter the wings rapidly, either in flight, as do the kingbird species, or while on a perch, as typified by the Cattle Tyrant and the Great Kiskadee.

The pendent nests of Myiobius *species tend to lack "tails" of camouflaged material and they usually have a slanted or pyramid-shaped roof of twigs or rootlets. This* ***Whiskered Flycatcher*** *has built her nest fairly low down in the undergrowth, but others are situated in the middle storey, or over a ravine for protection. This species, in common with several others in the genus, has a bright yellow rump and a distinctive foraging technique. Like the New World redstarts* (Setophaga), *and the Old World fantails* (Rhipidura), *they hold the tail cocked and fanned while foraging, and switch it conspicuously from side to side, possibly to disturb hidden insects.*

[*Myiobius barbatus insignis*, Alagoas, Brazil. Photo: Anita Studer]

Males of the doraditos in the genus *Pseudocolopteryx* engage in dramatic displays in association with their complex songs (see Voice), given both on the perch and in the air. The male Crested Doradito jerks the head back and forth as it sings, rapidly raising and lowering the crest while snapping the bill; the whole body appears to convulse in rhythmic hiccups as the male sings and performs bill-snaps. In the aerial display, the doradito flies upwards for several metres with butterfly-like wingbeats, the body hanging vertically, and occasionally throws back the head during a bill-snap.

Another type of display is demonstration of the nest-site, carried out by the phoebes. With the body held vertical and the tail fanned, the male phoebe hovers for 5-10 seconds just off the nest, which can be either a new one or an old one, or at a bare wall at an intended site. It may repeatedly land on the site and repeat the hover. The female often flies to the site or clings to the wall near the hovering male.

Artificial structures are widely used as nesting sites by the members of this family, and this habit is particularly marked among the phoebes. Across eastern North America, the most common nest-sites of Eastern Phoebes are on ledges such as support beams, drainpipes, window sills, bridge abutments, railroad trestles and barn rafters; the universal requirement is that the site has a closely overhanging protective feature, such as a roof, eave, deck, bridge structure or the like. Say's Phoebe (*Sayornis saya*) of western North America nests in abandoned mines and other buildings, bridges, barns, outhouses, wells, old cars and, once, even a horse trailer; recorded nest-sites of this species include rafters, girders, beams, shelves, electrical fixtures, ledges, drainpipes, eaves, machinery and mailboxes. The third member of the genus, the Black Phoebe, requires that the site be over water, and it regularly builds on bridges, on culverts, and under eaves of buildings bordering streams or lakes. The nesting habits of the phoebes stem from the tendency, under natural conditions, for all three species to nest on cliff ledges protected by closely overhanging rock. Studies of the reproductive behaviour of Black Phoebes in California revealed that a minimum of 2% to a maximum of 59% of nests were placed on natural structures.

The Great Kiskadee builds its bulky nest in a wide variety of locations that include man-made structures such as utility poles and transformers, multiple-dormitory birdhouses, and crevices in building facades. Many other tyrannine flycatchers besides the kiskadee exploit artificial sites. Social Flycatchers, for example, usually build on exposed snags, often over water, but they also use utility poles, abandoned houses, bridges, signposts, and even railroad trestles. In the USA, Eastern Kingbirds occasionally nest at the top of utility poles, and a study in British Columbia documented that 23% of nests of this species were on artificial structures.

Cavity-nesters such as the *Myiarchus* species frequently accept nestboxes, and also use hollow fence posts, old pumps, hanging buckets, pipes, and crevices in old buildings, while Streaked Flycatchers will also use nestboxes, as well as rain gutters, window sills and other crevices.

Nest form is extremely variable within the Tyrannidae. Acknowledgement that this variation provides important clues about evolutionary relationships within the family dates back to 1904, when von Ihering recognized several new subfamilies on the basis of their different nest structures, such as whether the nest was cup-shaped or pendent. As with other passerine families, including Furnariidae and Hirundinidae, among others, nest construction appears to be a relatively conservative life-history feature within lineages. Transitional stages are recognizable in some cases, suggesting evolutionary pathways between different stereotyped nest forms.

The commonest tyrannid nest type, taxonomically widespread and presumably primitive, is the open cup. The cup-nest takes on a wide variety of forms and is placed in many different kinds of physical sites, but its general structure is in all cases the same. The kingbirds build untidy nests of sticks, which they place high in trees, often in conspicuous spots in dead branches or snags over open water, thus inhibiting access by predators. At the opposite extreme, the Alder Flycatcher conceals its loose, untidy nest in dense foliage within a metre of the ground. The Eastern Wood-pewee and its *Contopus* congeners construct beautiful, carefully woven, tightly compact little cups with high edges, placed on open horizontal branches. All members of the genus *Elaenia* also build very neat open cups, but these are usually concealed in dense foliage; the Yellow-bellied Elaenia (*Elaenia flavogaster*) is a good example. The *Muscisaxicola* ground-tyrants and their relatives build open cup-nests directly on the

*The **Ash-throated Flycatcher** nests in cavities, a behavioural trait common to all* Myiarchus *flycatchers. While this usually means a hole in a tree, cavity-nesting refers to use of a host of natural or artificial sites that provide recessed protection, such as covered ledges or structural holes in buildings or machinery. They also use man-made nestboxes readily. Here, the chosen site is a woodpecker hole in a mature saguaro cactus* (Carnegiea gigantea). *This distinctive plant is common in the semi-deserts of the southern USA and northern Mexico, where this tyrant-flycatcher abounds. This cactus serves as a home for numerous cavity-nesting arid-country birds because of the enterprise of two woodpeckers (Picidae), the Gila Woodpecker* (Melanerpes uropygialis) *and the Northern Flicker* (Colaptes auratus). *Both of these species commonly excavate nests in the stems of columnar cacti.*

[*Myiarchus cinerascens cinerascens*, Arizona, USA. Photo: Dave Maslowski/ Maslowski Productions]

Most members of the genus Myiarchus *share one famous and intriguing habit: they adorn the nest with pieces of sloughed snake skin, animal hide, hair or plastic. These items are usually placed on the floor of the nest and wrapped about the interior of the nest. As demonstrated by this* ***Great-crested Flycatcher****, bits of snake skin are sometimes left dangling from the entrance. The definitive explanation for this behaviour has not yet been encountered, but it seems likely that the sight or odour of reptile skin dissuades predators from entering the dark cavity, as it could house a snake or some other hazardous tenant.*

[*Myiarchus crinitus*, Ohio, USA. Photo: Dave Maslowski/ Maslowski Productions]

ground, usually hidden among rocks. Many species in the subfamily Fluvicolinae construct cup-shaped nests on sheltered ledges of mossy banks, as typified by the Slaty-backed Chat-tyrant, on cliff faces, as does, for example, the Black Phoebe, and even on muddy riverbanks, as instanced by the Drab Water-tyrant. The Spectacled Tyrant weaves its cup-nest between reeds a metre above standing water in a marsh. One of the most distinctive cup-nests in the family is that of the Many-coloured Rush-tyrant, a tightly woven narrow cone of dried reeds attached all along one side to a single reed, and smoothed on the outside with a strange gum, giving the nest the appearance of having been cast in a mould like an ice-cream cone.

Nesting on cliff or mud ledges, riverbanks, rock crevices, and even directly on the ground has evolved independently in several lineages within the Tyrannidae, but apparently only within the Fluvicolinae. In all cases, these nests are modified open cups. Phoebes build large, tight nests of grasses and moss on ledges under protective overhangs. The somewhat looser grass cup of the Drab Water-tyrant is sited within a sheltered mud ledge on a riverbank, just one or two metres above the rushing water. The Chocolate-vented Tyrant in the monotypic genus *Neoxolmis* builds a shallow, open cup of dry grass and sticks, with a lining of feathers, directly on the ground in a sheltered location next to a grass tussock, shrub or rock. F. Vuilleumier analysed nest-site and clutch-size variation in 28 species of ground-tyrant and relatives. He concluded that open cup-nests in trees or shrubs are primitive for this assemblage, and that both ground-nesting habits and relatively small clutches, often of just two eggs, arose independently in the genera *Muscisaxicola* and *Neoxolmis* through separate invasions of semi-arid, resource-poor habitats in the Andes and in the Patagonian steppes, respectively.

In contrast to the above, the nest of the elaeniine genus *Corythopis*, the antpipits, is an oven-like, domed cup placed on the ground, with a side entrance. This nest is built with three different layers, comprising a cup, a lining and an outer covering, and is as unique among the Tyrannidae as are all the other features of these forest-floor flycatchers' ecology and life history (see Food and Feeding).

The partially domed cup built by the Mottle-cheeked Tyrannulet (*Phylloscartes ventralis*) seems to be an example of a transitional stage in the evolution of the fully domed nest. Covered, domed or ball-shaped nests with a side entrance appear in all three of the main tyrannid subfamilies and presumably evolved independently in each. Among the Elaeniinae, the two *Camptostoma* beardless tyrannulets build a messy, ovoid nest concealed in low vegetation or tucked into bromeliads or thick branches in a tree. In the Fluvicolinae, the Pied Water-tyrant and the closely related White-headed Marsh-tyrant construct loose globular nests of grass and feathers, which they attach to several reeds over standing water. In the third subfamily, Tyranninae, the Great Kiskadee builds a conspicuously bulky, ball-shaped nest of sticks and grass in a variety of locations, including low trees, dead snags and even utility poles. The similar nest of its relative, the Social Flycatcher, is made almost entirely of grass and placed

Tityras typically nest near the top of tall, dead snags in forested habitat, where they clearly benefit from the nesting activities of Melanerpes *woodpeckers by using abandoned holes. Here, a male* ***Masked Tityra*** *perches atop a broken stump in classic pose, while a female investigates a cavity in the trunk below, probably created by Yellow-tufted Woodpeckers* (M. cruentatus). *Both the woodpeckers and tityras are rather pugnacious birds, and it is common to see them bickering over nest-sites.* Melanerpes *family groups usually excavate several holes in a large dead tree, often creating enough room for both species. At times, groups of 3-4 adult tityras gather around suitable nest-sites, and it is possible that, as with the woodpeckers, they sometimes breed co-operatively. Further research is needed to clarify the breeding system of this interesting genus.*

[*Tityra semifasciata*, Alta Floresta, Mato Grosso, Brazil. Photo: Edson Endrigo]

in a huge variety of exposed locations, often over water. This species sometimes builds its messy grass nest inside natural cavities, suggesting an evolutionary precursor to the obligate cavity-nesting typical of some of its close relatives.

Cavity-nesting occurs in several groups of genera, mostly in the Tyranninae. The Sulphur-bellied Flycatcher and its congeners in *Myiodynastes* always nest in holes, as do all *Conopias* species for which relevant information is available. One of the latter, the White-ringed Flycatcher (*Conopias albovittatus*), usually uses tree holes, but it sometimes accepts the abandoned nest of a cacique as the most readily available "hole" in which to build. This behaviour, no doubt a response to the natural limitations in availability of tree cavities, clearly suggests a pathway towards the obligate nest piracy typical of the Piratic Flycatcher, discussed further below. All three species in the enigmatic genus *Tityra* nest in natural cavities, usually in old woodpecker holes quite high up in large dead snags.

Every species in the genus *Myiarchus* nests exclusively in natural or man-made cavities, such as woodpecker holes, knotholes in dead trees or limbs, tree-bark crevices and nestboxes. Hole-nesting also typifies all the genera in the *Myiarchus*-related assemblage, namely *Rhytipterna*, *Sirystes*, *Casiornis*, *Deltarhynchus*, *Ramphotrigon* and *Attila*. The *Myiarchus* flycatchers also share the peculiar habit of adding a piece of reptile skin, and often some animal hair or feathers, to the nest-lining. One of them, the Galapagos Flycatcher, suffers a shortage of holes, because no woodpeckers occur on those islands. This species, therefore, utilizes a variety of enclosed nest-sites, in addition to naturally occurring knotholes, and sometimes even uses the abandoned domed nests of several species of Galapagos finch. True to its lineage, the Galapagos Flycatcher adds hair and feathers to its nest, and this unusually confiding species has been photographed while attempting to retrieve human hair still attached to the person's head.

Members of the genus *Attila* display nesting behaviour that is transitional towards obligate cavity-nesting. The Bright-rumped Attila locates its bulky open cup-nest in a peculiar variety of natural crevices, such as the spot where a sapling grows adjacent to the sharply angled union of tree buttresses, or a deep nook amid masses of bromeliads. Other nests are built in shallow cavities of dead trees or knotholes, and the Grey-hooded Attila (*Attila rufus*) often chooses a hollow or a short tunnel in a clay riverbank in which to construct its bulky cup-nest.

The Long-tailed Tyrant is the only tyrant-flycatcher outside the Tyranninae to nest in holes. This fluvicoline species builds a thick mat of soft twigs and leaf petioles at the bottom of an old woodpecker hole or other natural crevice, almost always in a lone-standing dead tree and usually at a great height. Nest heights vary from 8 m to as high as 40 m above the ground. Only the female roosts in these holes, and she does so only immediately prior to and during incubation.

The most elaborate nests in the Tyrannidae are woven structures attached to and suspended by plant fibres from an overhanging twig. Most such nests are oblong or purse-shaped and have a somewhat concealed side entrance, sometimes protected by a short overhanging "visor". Pensile nests are typically lined with a thick mat of fine material such as seed down and soft feathers. In many cases, the nest is adorned with long "tails" of loose fibres or debris dangling below it, and such nests are often extraordinarily well camouflaged among debris, twigs or root banks, as is characteristic of, for example, those of the Spotted Tody-flycatcher. Elongated, pendent nests appear to be a universal trait among the pygmy-tyrants, tody-tyrants and tody-flycatchers, and have been documented for, among others, the Hangnest Tody-tyrant (*Hemitriccus nidipendulus*) and the Buff-throated Tody-tyrant (*Hemitriccus rufigularis*). Tody-flycatchers sometimes place these structures near active nests of paper wasps. The pendent nests built by the Sulphur-rumped Flycatcher (*Myiobius sulphureipygius*) and all other members of its genus are rounded and tightly woven, broader than those of the tody-tyrants, and are protected above by a steeply angled layer of twigs that overhang on all sides, forming a canopy with "eaves". These pyramid-shaped structures are less camouflaged than are other pensile-type nests, and instead are protected by being suspended at the high central point, from the end of long, vertically hanging twigs, vines or bamboo fronds, often over a stream.

Members of the genera *Mionectes* and *Leptopogon* often build a remarkably long, pendent nest with a tightly constructed, enclosed chamber having a roofed side entrance. These nests are camouflaged with a variety of liverworts, mosses, vine tendrils and grass, producing an irregular, messy-looking exterior that resembles flotsam left by receding floodwaters. Indeed, they

*The **White-rumped Monjita** does not dig its own holes, but relies instead on the excavations and constructions of other birds. The species is a cavity-nester with a predilection for open, sometimes almost treeless landscapes in the* cerrado *region of Brazil, and it often uses the abandoned burrows of Campo Flickers* (Colaptes campestris) *and Orange-fronted Parakeets* (Aratinga canicularis). *Both of these species frequently breed in termite mounds and ant hills, and, as shown here, the monjita is willing to do the same. Some individuals have been found nesting in the antechamber of thornbird* (Phacellodomus) *nests, which are huge, bulky pikes of sticks placed midway up in trees.*

[*Xolmis velatus*, Minas Gerais, Brazil. Photo: Anita Studer]

The nests of most tyrant-flycatchers are loosely woven, often constructed with grass, moss, and fine tendrils, and with relatively little use of stiff twigs or sticks. The nest of this ***Yellow Tyrannulet*** *is a typical example of the open-cup variety, and its architect is a widespread but local bird of dense tangled undergrowth, bamboo and vine tangles in the tropical lowlands of Central and South America. For a brief time included in the genus* Phylloscartes, *it is now generally separated in its own genus, as previously. It is possibly related to* Inezia, *which it more closely resembles in behaviour and vocalizations. Evidence from DNA studies is required to clarify its position.*

[*Capsiempis flaveola flaveola*, Alagoas, Brazil. Photo: Anita Studer]

are usually suspended from the tips of narrow, vertically hanging branches or rootlets under a protective ledge or fallen tree trunk within a ravine, and may even be placed over rushing, rocky streams. The most dramatic nest in the Tyrannidae, however, is that of *Onychorhynchus*, the Royal Flycatcher, the elaborately camouflaged hanging structure of which can approach 2 m in length.

Flatbills in the genera *Tolmomyias* and *Rhynchocyclus* construct pendent nests that are tightly woven with black vine tendrils and fungal hyphae. The nest shape is that of a retort, with a ball-like main pouch, and a woven tube descending at an angle from the top to form a side entrance. Both these genera often place their nests 10-20 m above the ground, hanging from an outermost branch of an exposed tree, in close proximity to an active wasp nest.

No discussion of the nesting habits of the Tyrannidae, however brief, would be complete without mention of the Piratic Flycatcher. This species is an obligate nest pirate, a trait that is almost unique among the tyrant-flycatchers; on rare occasions, the Great Kiskadee also engages in nest piracy. Piratic Flycatchers breed at the edge of tropical-forest openings, such as lake or river margins, open swamp or palm forests, and man-made clearings. At

The ***Crested Black-tyrant*** *builds an open cup-nest in the shady recesses of rocky banks, tending to choose sites that are well shielded from the sky. This photograph is brightly lit with flash, making the incubating bird unusually conspicuous, but it is usually very difficult to make out in the dimly lit interior of caverns. Unlike most other species in the genus* Knipolegus, *females of this species are almost as black as the males. It is not known why a few species are monomorphic, in this otherwise sexually dimorphic group, but in one other species the male has converged into female-like brown plumage.*

[*Knipolegus lophotes*, Minas Gerais, Brazil. Photo: Anita Studer]

*The messy cup-shaped nest of the **Fork-tailed Flycatcher** is sometimes built near the end of a branch, where it can be shaken loose in high winds. This incubating adult shows the yellow coronal patch typical of kingbirds; at most viewing angles these patches are difficult to see, but they are exposed and displayed to partners during courtship bouts. The female takes sole responsibility for incubation in this species.*

[*Tyrannus savana savana*, Minas Gerais, Brazil. Photo: Anita Studer]

the start of the breeding season, pairs perch high on a treetop for hours on end, incessantly calling a high-pitched "pee-de-de-de", and watch for other bird species to begin the construction of their nests. Piratic Flycatchers have been recorded as usurping the nests of a wide variety of species, and the nest types involved are similarly varied, although mostly of a bulky nature and, typically, with either a side entrance or a semi-concealed top entrance. Among them are pendent nests with side entrances, such as those of the flatbill genera *Tolmomyias* and *Rhynchocyclus*, the open-topped hanging nests of various icterid species in the genera *Icterus*, *Psarocolius* and *Cacicus*, the globular stick or grass nests with side entrances of, among others, several *Myiozetetes* species and *Pachyramphus* becards, and even large wasp or termite nests that have been hollowed out for nesting by trogons (Trogonidae). The Piratic Flycatcher carries out increasingly persistent, merciless harassing of the original owners, with dive-bombing flights and visits to the nest entrance. Both members of the pair take part in these relentless raids, which usually commence just as the nest is completed. The victims may put up considerable defence, but give up within one or two days. Occasionally, the flycatchers begin their harassment after incubation has begun, in which case they remove the eggs during the process of taking over the nest.

Among tyrannids in general, the female takes the most active role in nest construction, and often builds the nest with no assistance from her mate. Furthermore, for all well-studied species, females alone undertake the duty of incubation of the eggs. Clutch sizes vary from two to six eggs, with most tropical species laying only two to four eggs. The laying interval is daily for some species, such as the *Tyrannus* kingbirds, but many tropical species lay on alternate days. The incubation period varies from 12 days to 16 days among most species in both North and South America, reaching a peak of 23 days among a few of the smaller Central and South American species that build hanging nests.

Nestlings are brooded exclusively by the female, and they are usually provisioned by both sexes, the male playing a more active role. The Royal Flycatcher is an odd exception in that the male appears not to bring any food to the nest, even though he is present in a nest-guarding capacity throughout the nesting cycle. The chicks remain in the nest for periods varying from 12 days to 24 days, the period for the majority of the family falling in the range 14-17 days; in one exceptional case, a nestling period of 28 days was recorded for the Eye-ringed Flatbill. Young tyrannids can leave the nest in an explosive manner if the nest is disturbed prior to the natural fledging period. Nestling Eastern Phoebes, for example, can, if necessary, make relatively strong flights away from the nest only 15 days after hatching. Fledglings remain hidden in vegetation, but often emit loud begging calls. The fledged young of many tyrannid species roost together in a row, often in physical contact with one another on the branch.

Juveniles frequently spend many months living with their parents, and three individual Cliff Flycatchers were observed to be attending a single nest in Argentina. Despite that observation, however, no tyrant-flycatcher is known to exhibit co-operative breeding on a regular basis. Instead, among non-migratory tyrannids, the offspring of breeding pairs typically disperse immediately prior to the next breeding season.

Tyrant-flycatcher nests are not uncommonly preyed upon. The general rule in such cases is for the adults to renest. In a study of Social Flycatchers breeding along a lake margin in south-eastern Peru, one pair made six consecutive nesting attempts between September and January before it succeeded in fledging any young.

Movements

Tyrannidae constitutes by far the most mobile group of suboscine passerines. Almost a third of all tyrant-flycatchers engage in some form of movement between breeding and non-breeding grounds, consisting mainly of migration towards tropical or equatorial latitudes during northern and austral winters and returning in the opposite direction in the corresponding spring. In North America, all species that breed north of the USA-Mexico border migrate southwards in August or September and return between March and early May. Most migrate to Central or South America, leaving only the phoebes and scattered individuals of a few other species wintering within the southern USA. In South America, all species that breed in areas south from central Argentina migrate northwards during April-June and return from August to September. Even within tropical latitudes a few species make

seasonal movements. The Piratic Flycatcher, for example, leaves Central America in October and appears to begin breeding in the southern Amazon shortly thereafter. It is possible that individuals of this species breed at both ends of their range.

In terms of the geography of their wintering grounds, tyrant-flycatchers that breed in North America can be divided into two groups. Almost every species that breeds in the montane, semi-arid or lowland grassland habitats of western North America winters in Middle America, from mid-Mexico south to Panama, and extreme northern Colombia. These species reach peak winter-time abundance from southern Mexico through to Costa Rica. In contrast, those breeding in the deciduous forests east of the Great Plains or in coniferous and alder-shrub habitats across boreal Canada tend to migrate across the Gulf of Mexico to winter grounds in South America. These species reach peak winter-time abundance in western Amazonia and along the eastern base of the Andes. Within the southernmost states of the USA, the Eastern Phoebe is the only common wintering tyrannid east of the Great Plains, and the Black Phoebe is its replacement in the south-west. Southern Florida also captures a few additional species in extremely low numbers, including a small population of Great Crested Flycatchers and scattered individuals of the Vermilion Flycatcher, the Western Kingbird and the Scissor-tailed Flycatcher.

Two closely related *Empidonax* species that are sympatric over a broad zone in eastern North America divide their tropical wintering grounds in non-overlapping ranges. The Willow Flycatcher, which is the more southerly and westerly of the two, winters exclusively in Central America. The Alder Flycatcher, breeding across the boreal zone of Canada and northern USA, establishes wintering territories from September to April in the riparian thickets of the western Amazon Basin.

An exception to this pattern is the Sulphur-bellied Flycatcher, which breeds in the riparian forests of Mexico north to the USA border. Although it does, like the rest of the western flycatchers, migrate southwards through Central America, this species continues to South America and winters in loose aggregations of up to ten individuals in the western Amazon Basin. There, it is often found eating fruit in *Cecropia* stands and other river-edge habitats. Within the Amazon Basin, Sulphur-bellied Flycatcher alternates temporally with the closely related Streaked Flycatcher, an austral migrant.

The Eastern Kingbird has the most extensive migration of any tyrant-flycatcher. It breeds as far north as Alaska and northern Canada, and the entire population spends the winter south of the equator, from western Amazonia south to Argentina. On migration and throughout its South American non-breeding grounds, the Eastern Kingbird's behaviour would confuse those who know it only in summer. From May to July the species breeds as territorial, monogamous pairs in open country with scattered trees, and forages almost exclusively from exposed perches, from which it sallies after flying insects. In August, adults and juveniles begin to assemble in loose flocks of up to a few dozen individuals. Then, between mid-August and mid-September, flocks containing up to several hundred individuals move southwards on nocturnal migration. Often, these large flocks are visible at dusk or in early morning along the southern coast of the USA, over western Cuba and over eastern Mexico. By October they reach the Amazon Basin, where they appear to be nomadic, descending on large fruiting trees and remaining for days at a time, before gathering together and disappearing over the treetops to find fruit elsewhere. In these circumstances, the Eastern Kingbird is individually subordinate to its large, resident tropical relatives, but it overwhelms them by travelling in such large flocks. Many of these flocks reach southern Brazil and Argentina, before turning back northwards. Early arrivals are seen by March in the southern USA.

Tyrant-flycatchers are the dominant group of birds that migrate northwards from temperate or subtropical latitudes during the southern winter. Many members of the Fluvicolinae and the Tyranninae move north out of the southernmost portion of their breeding areas to populate the more northerly parts in Bolivia, Paraguay, southern Brazil and northern Argentina. Some species breeding in central Patagonia, such as the Austral Negrito, the Chocolate-vented Tyrant and the Rusty-backed Monjita (*Xolmis rubetra*), retreat northwards from their southernmost nesting grounds only as far as the central *pampas*. Some of the most southerly breeders, such as the Lesser Shrike-tyrant (*Agriornis murinus*) and the Cinnamon-bellied Ground-tyrant (*Muscisaxicola capistratus*), leave their breeding grounds en-

Even after the eggs have hatched, female tyrant-flycatchers continue to brood the nestlings for much of the day and at night. This is especially important during tropical downpours, when chicks can die from exposure and heat loss, if they are allowed to get wet. This ***Yellow-bellied Elaenia*** *protects her brood from the rain. Like most elaenias, she builds a tidy cup-shaped nest on top of a branch, and weaves pieces of lichen into the outer wall for camouflage.*

[*Elaenia flavogaster flavogaster*, Matoury, French Guiana. Photo: Tanguy Deville & Olivier Tostain/EcoBios]

tirely and move north to the equator or beyond for the non-breeding period. The southerly, nominate race of the Grey-bellied Shrike-tyrant (*Agriornis micropterus*) migrates northwards throughout the rest of Patagonia, but the northern race, *andecola*, appears to be non-migratory. Many of the ground-tyrants breed in the lowlands of southern Patagonia but spend the non-breeding season mainly high in the Andes of northern Argentina, Bolivia and Peru.

A number of southern breeders migrate to the Amazon forests. The southern races of both Swainson's Flycatcher (*Myiarchus swainsoni*) and the Streaked Flycatcher are present in the off-season throughout the Amazon Basin, where they overlap resident races from May to September, but they feed mainly in fruiting trees along clearings and edges. The Large Elaenia (*Elaenia spectabilis*) breeds from northern Argentina across southern Brazil, and winters in open river-edge habitats throughout the southern Amazon Basin. Similarly, the tiny Plain Tyrannulet (*Inezia inornata*) migrates northwards from open shrubland habitats in Bolivia and Paraguay and spends the non-breeding months in *Tessaria*-dominated early-successional growth along river margins in the south-western part of the Amazon Basin. During the austral winter, southern-breeding races of the Vermilion Flycatcher establish small, semi-permanent feeding territories along brushy margins of lakes and rivers in western Amazonia, and the Crowned Slaty Flycatcher, an open-country breeder, migrates north to exploit tall exposed treetops throughout Amazonia. This huge, productive region is the non-breeding home of yet another tyrannid, the Black-backed Water-tyrant, the southernmost populations of which move out of Argentina and take up residence along lakeshores and marshes in western Amazonia.

Long-distance movements are undertaken not only by the Nearctic tyrannids, but also by some of the austral migrants. The Small-billed Elaenia (*Elaenia parvirostris*) moves from the woodlands of Bolivia, Argentina and southern Brazil to a variety of open woodland and shrub habitats as far north as northern Colombia, coastal Venezuela and Trinidad. Equally remarkable is the Fork-tailed Flycatcher, the abundant southern race of which migrates in large flocks northwards as far as the Caribbean, and "overshooting" individuals are seen occasionally between March and September as far north as eastern North America. Similar instances of vagrancy are known for the Variegated Flycatcher, which moves from open country in southern Brazil and Argentina northwards to the *llanos* of Venezuela; extralimital records of this species have been made as far north as coastal Maine, in the USA.

Despite their seemingly weak, wren-like flight capabilities, marsh-breeding flycatchers such as the Many-coloured Rush-tyrant and the doraditos engage in extensive movements during the non-breeding season. The former moves northwards out of the southernmost areas of its range in south-eastern Argentina, and one was even recorded 170 km out to sea off the Rio Grande do Sul coast of south-east Brazil. The precise migratory status and distribution of the doraditos remain unclear. The Warbling Doradito (*Pseudocolopteryx flaviventris*) migrates northwards from southernmost Patagonia to extreme northern Argentina and Paraguay. The Subtropical Doradito (*Pseudocolopteryx acutipennis*) breeds in reedbeds and sedges high in the Andes, and then moves down to lowland marshes from May to early December; in Bolivia, for instance, it breeds at 2200-3550 m, but has not been recorded above 700 m during the austral winter. The rare Dinelli's Doradito (*Pseudocolopteryx dinelliana*) nests in a small area of northern Argentina, but in the non-breeding season it is found 500 km to the north, in southern Bolivia and western Paraguay.

Several mysteries remain with regard to the exact non-breeding, as opposed to breeding, distributions of South American tyrant-flycatchers. A number of *Knipolegus* species, such as the White-winged Black-tyrant, move either in elevation or in latitude between breeding and non-breeding seasons, but the precise limits of these movements are unclear. Likewise, the winter movements of many *Elaenia* species through the Amazon are poorly documented, in part because these birds become inconspicuous and difficult to identify in the forest treetops outside the breeding season.

A few tyrant-flycatchers are altitudinal migrants, descending to lower-elevation zones during the non-breeding season. Champion among these is the White-crested Elaenia, the southernmost race of which, *chilensis*, is an abundant breeder in *Nothophagus* forests of Chile and Argentina and winters broadly across the lowlands of the Amazon Basin, eastern Bra-

*Excessive solar radiation is almost as perilous for young birds as rain and cold. This **Eastern Kingbird** is shielding her brood from the sun's rays, an important defence against dehydration and overheating in the open habitats where this species nests. Here, the afternoon was sultry enough to cause the whole family to gape, a posture that helps lower blood temperature by evaporative cooling in the mouth and throat. Males in this species are not always the fathers of the offspring in their nest, as a result of extra-pair matings. Interestingly, conspecific brood parasitism is rife in some populations, so in some cases not even the female can be sure she is raising her own young.*

[*Tyrannus tyrannus*, New York, USA. Photo: Marie Read]

*Only a small proportion of the tyrant-flycatchers have been studied in great detail. For example, the breeding behaviour of the **Warbling Doradito** is almost unknown. This parent is removing a faecal sac from the cloaca of a young nestling. This species, like most other passerines, probably eats these packets very early in the nestlings' life, when their low digestive efficiency leaves many nutrients in the faeces. Later, adults dispose of these packets of waste material some distance from the nest, thereby ensuring that nest hygiene is maintained and that the nest itself is not made conspicuous by droppings.*

[*Pseudocolopteryx flaviventris*,
Depresión del Salado,
Buenos Aires, Argentina.

zil, Paraguay, Uruguay and Argentina. Another example is that of the White-bellied Tyrannulet, which breeds along the Andean foothills of Argentina up to as high as 3000 m, and then spends the May-September off-season across the low-lying parts of the northern half of the country.

It is hypothesized that the Piratic Flycatcher may breed at both ends of its migratory route. This species breeds from south-eastern Mexico south to Panama, but it is present in the northern part of this range only from March to August, and in Panama from January to September. It also breeds widely in South America, but the population breeding in the western Amazon Basin is present only from August to March or April. The fact that the Piratic Flycatcher is an extensively frugivorous species (see Food and Feeding) may make it energetically possible for it to raise a brood at each end of a migratory route, as has been demonstrated in North America for another fruit-eating and aerial-hawking bird, the Phainopepla (*Phainopepla nitens*).

The historical biogeographical importance of long-distance migration in the Tyrannidae bears mention. During the tens of millions of years during which North America was isolated from South America, only a single endemic bird family, the species-poor waxwings (Bombycillidae), consisted of sallying insectivores. Ecological opportunities therefore existed across North America for a radiation of birds that could exploit both flying insects and stationary arthropods accessible only to a sallying bird. The Tyrannidae constituted such a group, and the fact that many South American species engaged in continent-scale seasonal migrations presumably supplied a mechanism for colonizing the North American continent in the epochs preceding the creation of the Central American land-bridge. Of course, tropical birds invading the North American forests and grasslands faced snow-bound, leafless habitats devoid of active insects or other food for half of the year. For any such invading group to be successful, therefore, the colonizing species would have to have the propensity to head back south for the winter. It is presumably through this sequence of events and conditions that a few flycatchers in the highly migratory subfamilies Fluvicolinae and Tyranninae, including *Empidonax*, *Contopus* and *Sayornis* precursors in the former and *Tyrannus* and *Myiarchus* in the latter, were able to colonize North America and eventually to diversify in the continent.

Relationship with Man

Tyrant-flycatchers appear to have had little impact on human thinking. They are almost certainly best known to people by their vocalizations, although in many cases these are far from striking. Indeed, it is likely that a great number of the Tyrannidae have no effect whatsoever on humans. On the other hand, these birds are reasonably well accepted throughout much of their ranges, not least because they are often associated with human habitations.

In common with many other members of the genus Empidonax, *the **Yellowish Flycatcher** builds a bulky open cup of moss and liverworts, interlaced with a few fibrous rootlets, hairs, or other thin building materials. It usually tucks this structure into fissures or recesses in banks, tree-trunks and the like. The normal clutch consists of 2-3 eggs and incubation is performed entirely by the female.*

[*Empidonax flavescens flavescens*,
San Gerardo, Dota,
Costa Rica.
Photo: Marco Saborío]

In general, female tyrant-flycatchers are more actively involved than males in the breeding cycle, not only in producing eggs and contributing time to incubation, but also in providing for the nestlings. From what is known, the genus Pachyramphus *seems to fit this pattern quite neatly, as illustrated by this female* ***White-winged Becard*** *carrying a beakful of food for her offspring. As with so many of the true tyrannids, relatively little is known about the breeding behaviour of becards.*

[*Pachyramphus polychopterus polychopterus*, Alagoas, Brazil. Photo: Anita Studer]

As mentioned previously, the Great Kiskadee is the most vocally raucous member of the family. Its loud call is so familiar throughout most of the species' huge range that it has attracted a number of colloquial names. The well-known "kis-ka-dee" has been translated by various cultures into "Cristo-rey" (Christ the King), "Cristo-fue" (Christ has gone) and "Bem-ti-vi", the last version, meaning "saw you well", representing a Brazilian legend about the watchful kiskadee befouling a runaway thief.

Likewise, the ringing trill of the Scale-crested Pygmy-tyrant in the Central American and Andean montane forest is so distinctive that this species is sometimes referred to by local inhabitants as the "police-whistle bird".

The Royal Flycatcher's eye-catching display, with its remarkable crest raised and fanned and the head rhythmically twisted (see General Habits), has been witnessed only rarely in the wild. Nevertheless, it is considered so remarkable that it has not only been depicted in books but also featured on South American postage stamps.

Because many tyrant-flycatchers live in open habitats or at the edges of forest, and many seek exposed, elevated perches while foraging, members of this family are predisposed to associating with man-modified habitats and dwellings. A few species can even be termed "commensal" with humans, as they seem to favour and seek out certain conditions supplied by man over those in more natural habitats.

In North America, the phoebes, in particular, frequently utilize man-made structures for nesting (see Breeding). In this way they provide a welcome addition to the human environment. Indeed, so closely related to man-made structures are members of this genus that the great American poet Robert Frost ended a lovely poem, entitled *The Need of Being Versed in Country Things*, with the following verse, referring to birds still living around a recently burned farmhouse:

> For them there was really nothing sad.
> But though they rejoiced in the house they kept,
> One had to be versed in country things
> Not to believe the phoebes wept.

So far as is known, no member of the tyrant-flycatcher family has any adverse influence on human activities or interests.

Status and Conservation

The conservation problems facing bird populations in the Americas are well described in many of the field guides and monographs covering the region, as well as in other standard treatises such as *Threatened Birds of the World*, published by BirdLife International in 2000. Several other important compilations by this organization deal specifically with the Americas.

After Fringillidae and Psittacidae, Tyrannidae is the avian family with the highest number of threatened species in the New World. Of the total of 429 tyrannids, 47 species, or 11%, are currently considered to be of conservation concern. Two of these are categorized as Critical, nine as Endangered and 13 as Vulnerable, with a further 23 in the category of Near-threatened. Almost half of these are found exclusively or partly in Brazil, 13 of the total being restricted to that country and an additional nine occurring both in Brazil and in one or more of the adjacent countries of Bolivia, Paraguay, Uruguay and Argentina. Three of the 47 are endemic in Venezuela, two in each of Colombia, Peru and Argentina, and one each in Cuba, on Cocos Island, off Costa Rica, and on Robinson Crusoe Island, off Chile. A further three species are confined to Central America, and one occurs in Panama and Colombia, five in Ecuador and Peru, two in Peru and Bolivia, and two in several South American countries.

The above figures reflect the pattern of habitat destruction that has taken place in the New World, as illustrated by N. J. Collar and his collaborators. The destruction of the Atlantic coastal forests of Brazil, including humid forest, semi-deciduous forest, *restinga* and scrub, is the main reason for the high number of threatened species in Brazil. Similarly, the rapid conversion of native South American grassland and savanna into pastures and agricultural land is reflected by the fact that five of the tyrant-flycatcher species at risk occur in these habitats. Other regions facing rapid habitat destruction are Andean forests and scrub, and the lowland forests of the Tumbesian region of western Ecuador and Peru. Indeed, forest and scrubland habitats in many parts of Middle and South America are under threat, and these are the very habitats that harbour many of the members of this family. Nearly half of all globally threatened and Near-threatened tyrannids are usually found below 1000 m elevation, most of them inhabiting lowland forests, with only four and two spe-

*The **Streaked Flycatcher** is a common and conspicuous species throughout its large range in South America. It is somewhat kiskadee-like in shape and temperament, but has very different nesting behaviour. On rare occasions, clutches are laid in sheltered spots, such as the crotch of a palm tree, but usually they are placed in natural cavities such as the one shown here. The ideal site is a hole quite high in a tree or a broken-off stump, preferably in a clearing, or in parklike habitat. This species readily takes to old woodpecker holes, and in some regions it is a regular occupant of man-made structures, nesting in eaves or under broken roof tiles. In all these situations there is no nest as such; merely a scatter of twigs and other assorted items.*

[*Myiodynastes maculatus solitarius*, Minas Gerais, Brazil. Photo: Anita Studer]

cies having been recorded above elevations of, respectively, 3000 m and 4000 m.

Of three island species, two are classified as Vulnerable. These are the Cocos Flycatcher, restricted to the island of that name lying about 500 km off the Pacific coast of Costa Rica, and the Noronha Elaenia (*Elaenia ridleyana*), which lives on the Fernando de Noronha Archipelago, off north-east Brazil. The third, the Juan Fernandez Tit-tyrant (*Anairetes fernandezianus*), is confined to Robinson Crusoe Island, off Chile, and is Near-threatened.

Taxonomically, *Phylloscartes* contains the highest numbers of tyrannids considered to be in trouble. Of its 16 species, five are globally threatened and a further three are considered Near-threatened. Again, the main reason is the destruction of the Atlantic coastal forests, where six of these eight species live. Two of them, the Alagoas Tyrannulet (*Phylloscartes ceciliae*) and the Minas Gerais Tyrannulet (*Phylloscartes roquettei*), are the only tyrannids placed in the highest of threat categories, that of Critical. The related genus *Pogonotriccus*, previously lumped with *Phylloscartes* (see Systematics), is also of concern, with two of its seven members listed as Near-threatened and one as Endangered.

Fortunately, so far as is known, no tyrannid has yet become extinct, but the first two casualties may soon be the two Brazilian tyrannulets mentioned in the preceding paragraph. Both also epitomize the typical threats that face tyrant-flycatcher species. In Alagoas state, where the Alagoas Tyrannulet was discovered in 1983, massive clearance of the humid forests around Murici, largely for sugar-cane plantations and pastureland, has reduced this habitat to a mere 2% of its original cover, which extended through both Pernambuco and Alagoas. Even remaining forest tracts are threatened by small-scale cultivation, by timber and firewood removal, and by the spreading of fires from adjacent plantations. Only recently has the last forest remnant, of about 30 km², received some protection within the Murici Ecological Reserve, but the establishment of this reserve has not halted forest degradation and destruction, because these privately owned forests continue to be used for selective logging and are still threatened by the spread of fires. The best areas of surviving forest now lie almost exclusively within a privately managed reserve known as Fazenda Bananeira, covering 12 km². The Alagoas Tyrannulet has been found in two additional reserves, but these are also no more than tiny remnants of the vast forest that once extended along almost the entire Atlantic coastline of Brazil.

The semi-deciduous forests inhabited by the Minas Gerais Tyrannulet have experienced a similar fate to that described above. They represent probably the most threatened habitat in central Brazil owing to their valuable timber and their relatively fertile soils. The tyrannulet may already be extinct at its type locality in Minas Gerais, where the gallery forests on both banks of the São Francisco River have been extensively removed for timber and charcoal, limestone-quarrying, pasture and the cultivation of soya beans and other agricultural produce. The occurrence of the species in a newly established national park is a source of some optimism, although the size of this population must urgently be determined. Luckily, the species has been found at two additional localities to the south, where patches of forest remain, but a major irrigation project is under way that has already led to the deforestation of large areas; unless these extremely small sites are effectively protected or further populations are found, there must be a grave risk that this species will very shortly become extinct.

This tale of rapid habitat destruction leading to increasingly small populations living in fragmented remnants of what used to be large and continuous habitats is repeated for almost every one of the 24 globally threatened tyrannids and the 23 Near-threatened ones. Tyrant-flycatchers are too small to be considered worthy of hunting, and are not targeted for commercial exploitation as cagebirds. Rather, the primary threat for virtually all tyrannids is habitat destruction, while a few species are also adversely affected by tourism, introduced predators, herbivores and competitors, and nest parasitism by cowbirds (*Molothrus*, *Agelaioides*).

Degradation, fragmentation and destruction of forest habitats top the list of threats, with the conversion of native grassland and savanna into pastureland and agricultural areas the second most important factor. Destruction of scrubby and marshy habitats also places some flycatcher species at risk. Forest habi-

*As with all becards, the nest of the **Chestnut-crowned Becard** is a distinctive bulky structure built of twigs, moss and leaves. These messy globular nests are often placed in the canopy or middle storey of isolated trees, or trees at forest edge. Becards either suspend these nests from an overhanging branch or, more commonly, wedge them into a fork between branches. The side entrance usually faces downwards, thus providing shelter and camouflage, and the incubation chamber itself is positioned near the top of the structure. The clear preference for isolated trees in many becards is an adaptation to keep the nest away from the customary foraging areas of arboreal mammals and reptiles.*

[*Pachyramphus castaneus castaneus*, Atlantic forest, SE Brazil. Photo: Luiz Claudio Marigo]

*This **Short-tailed Pygmy-tyrant** is arriving at its nest with a beakful of insects. An obligate insectivore, it must work hard to provision its brood, visiting the chicks every few minutes throughout the day. Weighing only 5 g, this species and its congener the Black-capped Pygmy-tyrant* (Myiornis atricapillus) *are the smallest passerines in the world, with tails so short as to seem vestigial. Its wings are also short and rounded, like those of cicadas or beetles, and this bird almost looks beetle-like when it whirrs weakly from perch to perch in the middle storey. These chicks have begun begging before the arrival of the adult at the nest, and it seems plausible that the distinctive whirr of wings approaching may alert them to the imminent arrival of food. The pendant nest is typical of all species in the tody-tyrant and pygmy-tyrant assemblage.*

[*Myiornis ecaudatus ecaudatus*,

tats become degraded through selective logging for timber, firewood and charcoal, understorey disturbance caused by timber extraction and livestock grazing, small-scale cultivation, the spread of fires from adjacent areas, and soil erosion in the wake of these activities and occurrences. Wholesale clearance of forests is largely a result of the desire to create pastureland for livestock farming and plantations for various commercially exploitable products, such as pine and eucalypt (*Eucalyptus*) trees, mangos, bananas and other fruits, sugar cane, soya beans, marijuana, coca and coffee, the last of those at least providing habitat for some birds in the form of coffee shade trees. Generally, forests on fertile soils are the first to be cleared, but more and more of those on marginal soils are also being converted. Forest destruction is also frequently the outcome of oil extraction, mining, irrigation projects, urbanization, and infrastucture developments such as road-building. Road-building is especially destructive, not so much in terms of the size of the area lost, but because it fragments previously continuous habitats and opens them up to human intrusion and, as a consequence, further environmental damage.

In some areas, deforestation has been so intense that virtually all pristine forest outside protected areas will very soon be destroyed. This is the case with, for example, the Atlantic Forest of coastal Brazil, the lowlands forests in the Tumbesian region of western Ecuador and north-west Peru, and the lowland forest in Chiriquí, in Panama. Unprotected patches of intact forest remain only on inaccessible slopes at higher elevations, and are usually rather small and severely fragmented. Worse still, even formally protected areas often suffer from human impacts, especially when protection cannot be enforced for lack of human and financial resources. Many reserves suffer from selective logging, understorey disturbance through livestock grazing, illegal settlements and small-scale cultivation, and illegal fires. Moreover, they are sometimes subjected to wholesale conversion to pasture and plantations, this being especially the case in areas of armed conflict, where coca production is widespread.

A good example of the problem can be seen in eastern Brazil, where a string of parks and reserves stretches from southern Bahia south to Rio Grande do Sul, affording protection for many of that country's threatened bird species, including tyrannids. Many of these reserves, however, are small and isolated, rendering their bird populations vulnerable to "edge effects" and "island effects", which may reduce immigration and gene flow and, at the same time, increase inbreeding depression, as well as predation and cowbird parasitism. Furthermore, most of these reserves, especially the larger ones, protect mainly montane habitats, whereas the lowland forests are given only minimal protection.

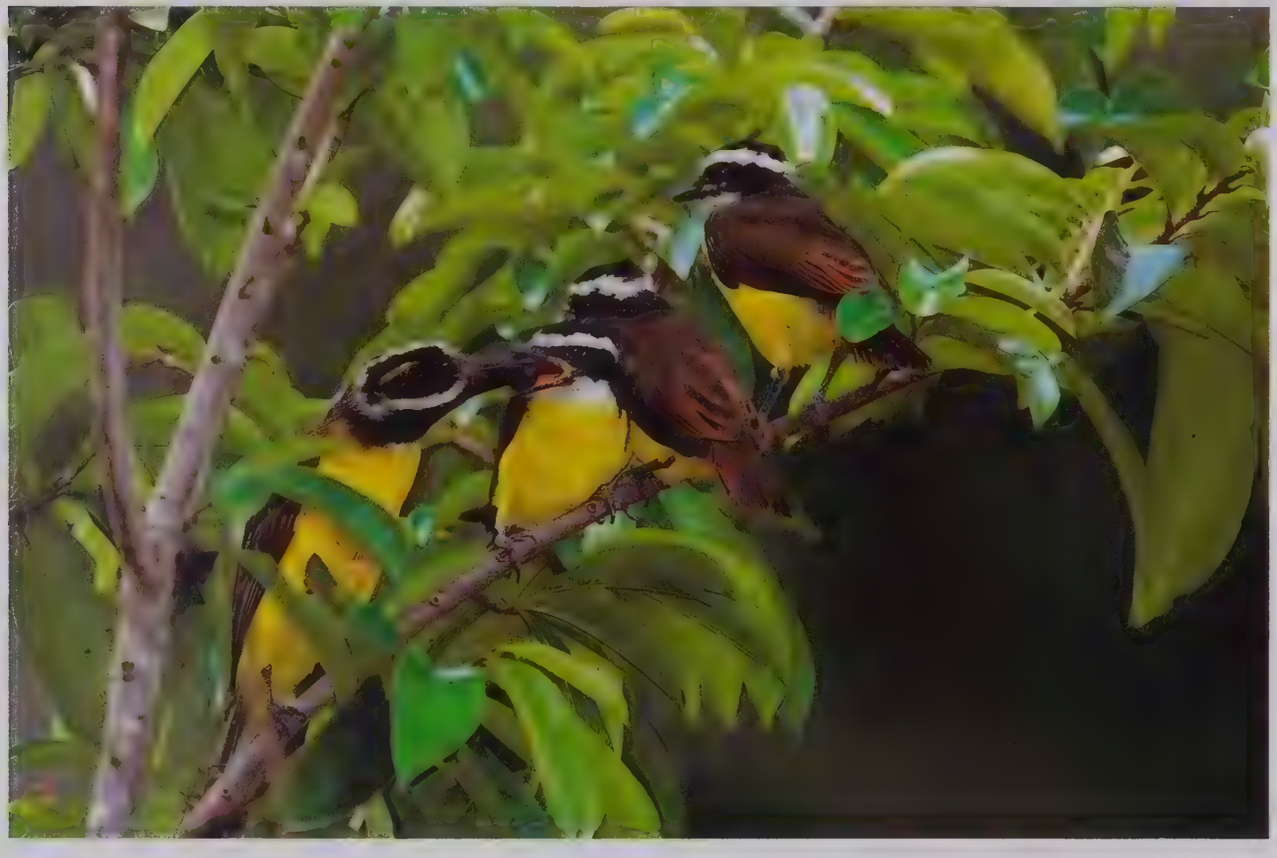
The threats facing native grasslands and savannas in South America are very similar, with conversion for pasture and plantations being the main one, but most of the other factors mentioned above also play a role. For example, two-thirds of the *cerrado* region in central Brazil had been heavily or moderately altered by 1993, with much habitat conversion having been actively encouraged by government land-reform policies since the 1950s.

With very few exceptions, tourism and introduced predators, herbivores and competitors affect only island species. Tourism has had a strong impact on habitats in the Caribbean, especially on the smaller islands such as the Lesser Antilles, where loss of habitat has been most severe on islands with no inaccessible mountainous areas. The Lesser Antillean Pewee (*Contopus latirostris*), the Grenada Flycatcher (*Myiarchus nugator*) and the Lesser Antillean Flycatcher (*Myiarchus oberi*) have certainly suffered from the large-scale destruction of native forests, although none of them is considered yet to be at any risk. Away from the West Indies, two other island species, the Noronha Elaenia and the Cocos Flycatcher, are already globally threatened, and both may be put under even more pressure by future increases in tourism. In a similar context, the continuing development of beach-front dwellings is destroying the *restinga* forests inhabited by the Restinga Tyrannulet (*Phylloscartes kronei*) in south-eastern Brazil, and this tyrannid, too, is globally threatened.

Introduced mammalian predators such as coatis (Procyonidae), cats and rats (*Ratus*) may adversely affect the Cocos Flycatcher, the Juan Fernandez Tit-tyrant, the Noronha Elaenia and

The most common brood size in tropical tyrannids is two eggs, with a few species even laying only one egg during most breeding attempts. Some tropical species lay up to four eggs, and a few Nearctic species will lay up to six. This ***Boat-billed Flycatcher*** *is raising two chicks, one of which is receiving a large insect that it will work hard to swallow. With the biggest bill of any tyrant-flycatcher, this species snatches bulky prey items, such as reptiles, amphibians, orthopterans and moths, from leaves and branches. Unlike the similar Great Kiskadee* (Pitangus sulphuratus) *it builds an open nest, untidily constructed on top of forked or intersecting branches, and it announces its identity, not with strident yelling, but with coarse, nagging calls from the treetops.*

[*Megarynchus pitangua pitangua*, Maranhão, Brazil. Photo: Anita Studer]



*Tyrannid nestlings fledge 12-24 days after hatching, but in most cases the nestling period is 14-17 days. When well-developed broods are disturbed, they are capable of abandoning the nest and fluttering away when even younger. Prematurely evacuated birds tend to have poor flying ability, however, making them highly vulnerable to predation. After hatching, fledglings usually conceal themselves in dense vegetation. This young **Great-crested Flycatcher** is fully exposed on a dead snag, probably having just recently left its hole for the first time. Both members of the pair feed the young actively during the post-fledging period.*

[*Myiarchus crinitus*, Ohio, USA. Photo: Dave Maslowski/ Maslowski Productions]

the Galapagos Flycatcher, while introduced herbivores such as cattle, deer, goats, pigs and sheep have a serious impact on the understorey vegetation within their forest habitats. Nevertheless, the first two of those species, at least, appear to be tolerant of degraded understoreys. Nest competition from the introduced hole-nesting Common Starling (*Sturnus vulgaris*) may cause some problems, at least locally, for the Great Crested Flycatcher and possibly other North American tyrannids.

Certainly, parasitism by cowbirds has a negative effect on some tyrant-flycatchers, including the Acadian and Willow Flycatchers in North America, as well as a Vulnerable tyrannid in central South America, the Black-and-white Monjita. Cowbird parasitism, however, is really only a secondary effect of habitat fragmentation, as the cowbirds benefit from the creation of open spaces and edges, so that parasitism by these birds almost invariably increases with habitat degradation and fragmentation. The

*Fledged broods of tyrant-flycatchers often remain in close proximity to each other for several days. During this time, they may roost together on the same perch, even touching shoulder-to-shoulder in a row. After attaining independence, the young of most non-migratory species linger on the natal territory until shortly before the next breeding season. This **Great Kiskadee** has raised a brood of three, with which it will associate over the coming months. Even at this young age, they develop a plumage remarkably similar to that of adults. As in most juvenile tyrannids, the back and wing feathers are edged somewhat more rufous or buffy than in the adults.*

[*Pitangus sulphuratus sulphuratus*, Savane Cézaré, Macouria, French Guiana. Photo: Tanguy Deville & Olivier Tostain/EcoBios]

Tyrant-flycatchers are often passed over as drab little brown birds, but several species are confiding friends right on our doorstep. ***Say's Phoebe****, for example, is a celebrated bird of the American West, familiar in rural regions because of its habit of living alongside people. It nests freely in man-made structures, making use of barns, bridges, wells, abandoned mines, electrical fixtures, old cars, trailers, outhouses, shelves, rafters, girders, ledges, drainpipes, eaves and even on old cow skulls in cabins. Some nests are placed in mail boxes, even causing complications with the local mail service.*

[*Sayornis saya saya*, California, USA. Photo: Dave Maslowski/ Maslowski Productions]

current spread and increase of cowbirds all over the Americas could, therefore, affect many more tyrant-flycatcher species in the near future.

While the causes of the decline of most threatened tyrannids appear relatively obvious, two species have declined for reasons that are largely unknown. The White-tailed Shrike-tyrant (*Agriornis andicola*) is classified as Vulnerable because it has declined precipitously in recent decades, and it is now very rare and local in open grassy and shrubby areas in the high Andes, from Ecuador south to northern Argentina. Some authors have suggested habitat alteration as the reason for the rapid diminution in its numbers, but most of its habitat remains relatively undisturbed and may have even expanded through burning and grazing. This species may, however, be especially sensitive to very slight habitat modifications, such as the loss of its nesting plant, *Puyas raimondii*, or it may simply be outcompeted by one of its congeners, the Black-billed Shrike-tyrant (*Agriornis montanus*). One of the rarest and most globally threatened tyrannids of all, the Giant Kingbird, now occurs only in a few large, remnant tracts of undisturbed woodland in Cuba. Habitat loss from logging and agricultural conversion is presumably a contributory factor, but more research on this Endangered species is needed in order to determine its precise ecological requirements.

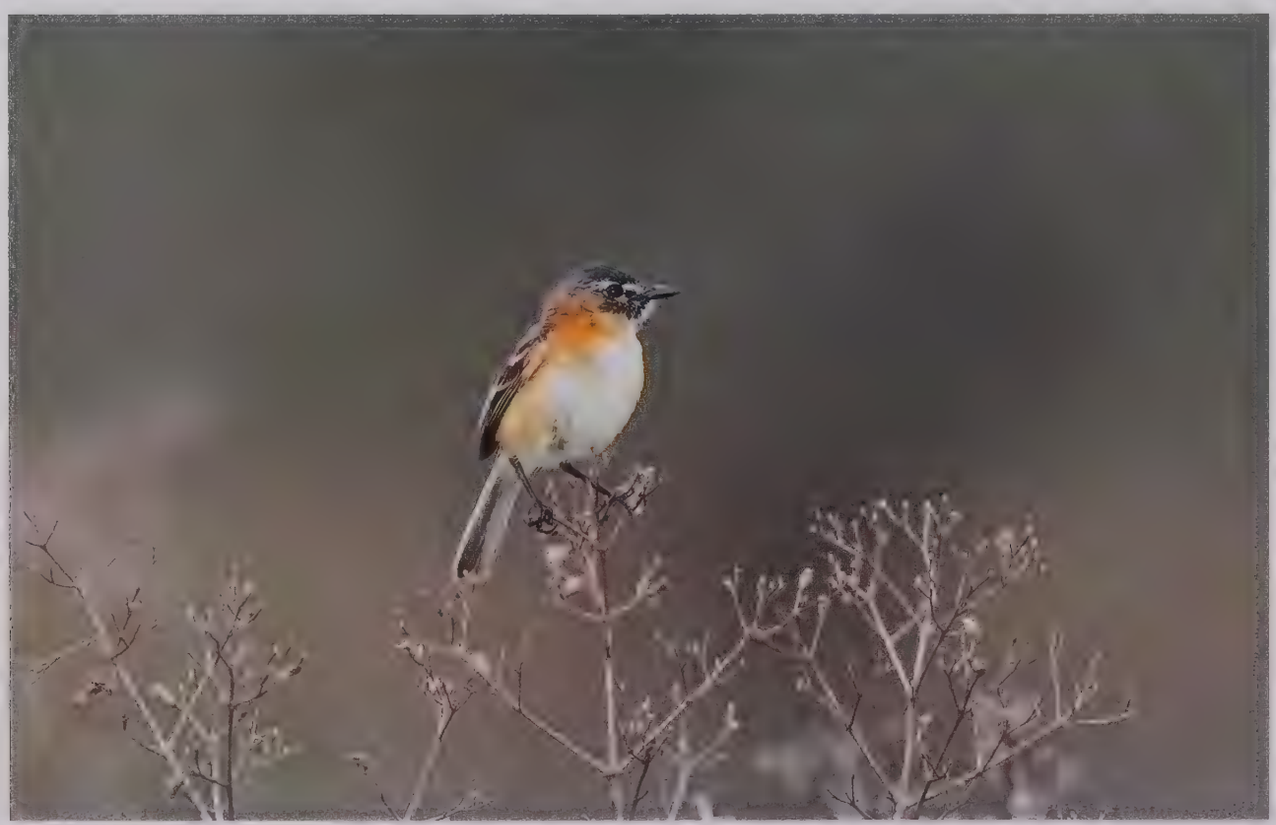
Although hunting is normally not a threat to tyrant-flycatchers, a few species are sometimes used by children as targets for slingshots. Both the Noronha Elaenia and the White-tailed Shrike-tyrant have been mentioned in this context, and in the case of the latter species it may be one of the reasons for its otherwise rather puzzling decline.

Considerable uncertainty surrounds the conservation status of many members of the Tyrannidae, and for quite a number of reasons. One is, of course, pure ignorance of the very existence of species, and the discovery of eleven "new" tyrannids within the last two decades speaks volumes about the situation. In order of date of publication of description, these are the Cinnamon-breasted Tody-tyrant, the Alagoas Tyrannulet, the Antioquia Bristle-tyrant (*Pogonotriccus lanyoni*), the Restinga Tyrannulet, the Bahia Tyrannulet (*Phylloscartes beckeri*), the Cinnamon-faced Tyrannulet (*Phylloscartes parkeri*), the Orange-eyed Flycatcher, the Foothill Elaenia (*Myiopagis olallai*), Johnson's Tody-tyrant, the Mishana Tyrannulet and the Chapada Flycatcher. Naturally, having avoided detection for so long, many of these recently discovered species have very small ranges, and consequently four of the eleven are immediately considered globally threatened and a fifth is listed as Near-threatened. Other reasons for their belated discovery are, of course, identification problems, as *Phylloscartes* tyrannulets, *Pogonotriccus* bristle-tyrants, *Tolmomyias* flycatchers and the elaenias, among others, are all notoriously difficult to identify, at least visually. The increased use in recent years of vocalizations for identification purposes led to the discovery of several of the above species, and will undoubtedly aid in the discovery of yet more taxa and the splitting of known species, but the characteristics of these most recently discovered tyrannids should also make us wonder whether one or more elusive tyrant-flycatcher species have already been lost to the world without our ever having been aware of their existence.

In a similar vein, rediscoveries can immediately change the conservation status of a species. For example, both the Buff-cheeked Tody-flycatcher (*Poecilotriccus senex*) and Pelzeln's Tody-tyrant (*Hemitriccus inornatus*) were until recently known only from a single specimen of each, collected in 1830 and 1831,

*The **Juan Fernandez Tit-tyrant** is endemic to the island of Robinson Crusoe, in the Juan Fernández archipelago, far off the coast of Chile. Its presence on this remote island bears witness to the dispersal and migratory capabilities of certain small tyrannids, particularly those at high altitudes and latitudes. Despite its tiny range, several thousand birds are thought to survive, even in fairly degraded habitat. Although it is in no immediate danger of extinction, the introduction of mammalian predators such as cats and rats might pose a problem, and the species is currently classed as Near-threatened.*

[*Anairetes fernandezianus*,
Juan Fernández Islands,
Chile.
Photo: Roland Seitre]



respectively, and were therefore considered possibly extinct or, at the very least, extremely rare. The Buff-cheeked Tody-flycatcher, however, was rediscovered in 1993, at the type locality in central Brazil, and found to be fairly common within pristine habitat. Likewise, Pelzeln's Tody-tyrant was refound in 1992 about 1000 km away from its north-west Brazilian type locality, a discovery that immediately extended the species' known range quite dramatically; it was subsequently found in several other localities with good habitat. Consequently, both of these tyrannids, previously regarded as extremely rare at best, are now considered not to be under threat.

Two other rediscoveries, however, led to improved assessments of conservation status, but with much less favourable prospects. Kaempfer's Tody-tyrant was first discovered in 1929 and was recorded again at the type locality in 1991; with just two more localities added recently, it is an Endangered species. The Minas Gerais Tyrannulet was discovered for the first time by scientists in 1926, found at the same locality in 1977, and recorded at three further sites more recently. One of these new localities is protected, but the species must still be considered to be Critical.

Fortunately, these four rediscoveries, made after many long decades without any sightings of the species involved, mean that no tyrant-flycatcher is currently thought to be extinct. Nevertheless, several species are precariously close to final extirpation.

Increased taxonomic knowledge can change the perceived conservation status of a population. The Chapada Flycatcher was split from the Suiriri Flycatcher in 2001, on the basis of differences in its vocalizations and display behaviour (see Systematics). Immediately, this new taxon may become a species of conservation concern, as its habitats are being eroded by livestock farming and large-scale cultivation of cash crops. Likewise, two of the subspecies of the Royal Flycatcher, *occidentalis* and *swainsoni*, are of immediate conservation concern, as their coastal rainforests are severely threatened by rapid deforestation and fragmentation. Both races have been elevated to species status by several authors, and are, in fact, currently listed as Vulnerable and Endangered, respectively. A final instance of the way in which taxonomic changes influence assessments of conservation status concerns the recent splitting of the Greenish Tyrannulet (*Phyllomyias virescens*) into three distinct species: one of the two newly erected species, Urich's Tyrannulet (*Phyllomyias urichi*), has immediately been categorized as Endangered, and the other, Reiser's Tyrannulet (*Phyllomyias reiseri*), is possibly on the brink of becoming threatened. These examples illustrate that taxonomic treatments that underestimate species-level biodiversity may lead to many unique life forms being overlooked when conservation priorities are being set.

Improved knowledge of the distribution and abundance of species can also lead to reassessment of their conservation status. For example, the Sharp-tailed Tyrant was recently redis-

*The **Bearded Tachuri** is listed as Near-threatened. It occurs over a large area from Colombia and Venezuela to Bolivia and Argentina, but its populations are small and highly localized in specialized habitat. Natural retreat of native grassland produced this relictual range, and the habitat is also extremely susceptible to destruction through the development of rural economies and the inexorable expansion of agriculture. Vast areas of prime grassland are burnt or ploughed annually, and converted to grazing lands or crops. Fortunately, the Bearded Tachuri seems to tolerate a fair degree of grassland perturbation, and it remains fairly common in several regions.*

[*Polystictus pectoralis pectoralis*,
Itirapina,
São Paulo, Brazil.
Photo: Edson Endrigo]

*The tail of the **Sharp-tailed Tyrant** is unique in the family: it is made up of only ten rectrices, all of which are distinctly slender and stiffened, with degenerate barbs. This structure is more akin to the tails of* Synallaxis *spinetails than to that of any other tyrannid. The bill is also unusual, being rather short and stubby, perhaps related to the fact that seeds form a part of the diet. The Sharp-tailed Tyrant is a bird of grassy plains in Bolivia, Brazil, Paraguay and Argentina. It is treated as Near-threatened because its populations and favoured habitat are shrinking rapidly over many parts of its range. In a few areas, however, it remains widespread and locally quite common.*

[*Culicivora caudacuta*, Serra da Canastra, Minas Gerais, Brazil. Photo: Edson Endrigo]

covered in eastern Paraguay and recorded for the first time in La Paz, in Bolivia, and Entre Ríos, in Argentina; this tyrannid, currently listed as Near-threatened, may therefore be less at risk than was hitherto believed. Likewise, another Near-threatened member of the family, the Russet-winged Spadebill (*Platyrinchus leucoryphus*), is now thought to be more common within its range in Paraguay and south-east Brazil as a result of a recent increase in records following improved knowledge of its vocalizations. Many species of tyrant-flycatcher, as they sit motionless for long periods or hide in the canopy or dense vegetation, are notoriously difficult to detect and, equally, many are very difficult to identify visually and, sometimes, even acoustically. With advances in knowledge and understanding, we can expect reports of range increases and higher abundances for many species in the future. For example, the Glossy-backed Becard (*Pachyramphus surinamus*) has been reported from three widely separated localities; given its secretive canopy-dwelling behaviour, however, it is likely that further intensive fieldwork will lead to additional records in the intervening areas, thus filling in the gaps in this species' distribution and probably extending its recorded range. This is just one of at least 61 tyrannid species which field ornithologists such as S. L. Hilty and R. S. Ridgely have cited as being often overlooked. The publication of new, up-to-date field guides and the increased use of vocalizations as an identification tool will undoubtedly improve our knowledge of the conservation status of many tyrant-flycatcher species.

The migratory habits of many tyrannids (see Movements) also make it difficult to assess their true conservation status. The abundances of some migratory species may vary greatly from one year to another, as at the southern tip of South America, where numbers of both the Cinnamon-bellied Ground-tyrant and the Chocolate-vented Tyrant appear to fluctuate to such an extent that various authors disagree on the population levels of these species, making any assessment of their conservation status more difficult than it is for resident species. The migratory habits of several species were also observed recently from a crane overlooking the forest canopy in southern Venezuela, as part of the Surumoni Crane Project. At the onset of the rainy season, a marked increase in tyrannid flocks moving across the rainforest canopy was noted, suggesting that insectivorous species undertake short-distance or long-distance migrations to follow rainfall patterns. Observations of resident as well as migrating birds in the canopy may thus lead to a better understanding of their overall abundance, range and movements. Many tyrannid species rarely seen from the ground may, in fact, appear more common once canopy access has allowed better opportunities for observation.

Moreover, the canopy-dwelling habits of many flycatcher species make them, in general, less vulnerable to habitat frag-

*The **Serra do Mar Tyrannulet** qualifies for the Near-threatened category on the basis of its small range, and the disastrous loss of habitat in the Atlantic Forest. The future of this species looks relatively secure because it inhabits the understorey of montane forest, large tracts of which receive protection in a number of important parks and reserves. For example, it survives in good numbers within Itatiaia National Park and southwards through the Serra do Mar. Permanent effective habitat protection is vital for this species, and for many other taxa endemic to the region.*

[*Phylloscartes difficilis*, Campos do Jordão, São Paulo, Brazil. Photo: Edson Endrigo]

*The **Salinas Monjita** was initially described as an isolated northern race of the Rusty-backed Monjita* (Xolmis rubetra). *Once elevated to species status, its tiny global range caused concern and the taxon was listed as Near-threatened. It is restricted to patchy scrub and salt-impregnated flats around Salinas Grandes, in north-west Argentina, a habitat unlikely to suffer much developmental pressure in the near future. Like its Patagonian relative, this monjita is semi-terrestrial, looking oddly like a lark (Alaudidae) or wheatear* (Oenanthe) *at a glance, when running around on the ground.*

[*Xolmis salinarum*, San José de las Salinas, Córdoba, Argentina. Photo: José & Adriana Calo]

mentation than are understorey birds such as the antbirds. This is because canopy species seem more inclined to cross large gaps within the forest, whether natural ones, such as savannas or rivers, or man-made ones, such as roads and clearings. Thus, many tyrannids are well adapted to conditions of forest edge and secondary vegetation, where they eat small berries and insects, and may suffer less from habitat degradation than do avian taxa more dependent on closed forests. It is likely, therefore, that a good number of the 380 or so tyrannid species not globally threatened or Near-threatened will remain so within the foreseeable future.

The ecological characteristics that make a species especially vulnerable to extinction are a small total range, a low-density population, and specialization on a habitat that suffers rapid rates of degradation, fragmentation and destruction. Many tyrant-flycatchers have small ranges, and three species are considered threatened simply because they occur on small islands, even though the forest habitats on which the Noronha Elaenia, the Cocos Flycatcher and the Juan Fernandez Tit-tyrant depend appear relatively secure. On the other hand, some species with large geographical ranges may still occupy only small areas within these ranges. Habitat specialization is almost always the reason for this, and two prime examples are of species restricted to narrow bands of successional riparian forest and species confined to tree-line habitats in the high Andes. Such linear habitats can sustain only very small bird populations, but the tendency to illustrate ranges by "filling in" areas on maps with continuous shading may vastly overstate the true abundance of the species concerned.

One species that seems to occur naturally at low densities is the Royal Flycatcher. The fact that, for breeding, it apparently requires humid forest with streams below may explain its rarity even in pristine habitat. Consequently, the two subspecies with small ranges, western *occidentalis* in the coastal lowland forests of the Tumbesian region and eastern *swainsoni* along the Atlantic coast of south-east Brazil, are especially threatened by the rapid destruction and fragmentation of their habitats. Other globally threatened taxa that appear to occur at naturally low densities are the Rufous-sided Pygmy-tyrant, Kaempfer's Tody-tyrant and the White-tailed Shrike-tyrant, and the Near-threatened Russet-winged Spadebill is similarly disadvantaged.

As habitat degradation, fragmentation and destruction proceed unabated, the future prospects of most species now considered to be at risk will almost inevitably deteriorate. Likewise, the status of some others not yet placed in this category may well change. The combined factors of small range size, intolerance of degraded habitats and rapid habitat destruction are the foremost cause for concern. A whole suite of species falls within this sphere, and all should be closely watched in the future. They include, among others, the Pacific Elaenia (*Myiopagis subplacens*), the Slaty Elaenia (*Elaenia strepera*), the Unstreaked Tit-tyrant, the Mishana Tyrannulet, the Peruvian Tyrannulet (*Zimmerius viridiflavus*), the Ecuadorian Tyrannulet (*Phylloscartes gualaquizae*), the Inca Flycatcher and the Sooty-crowned Flycatcher (*Myiarchus phaeocephalus*). A further five species are already included on the red lists of Ecuador and Colombia, and two of these, the Spectacled Bristle-tyrant and the Yellow-throated Spadebill (*Platyrinchus flavigularis*), may be on the brink of globally threatened status, while the three others, the

Unusual tarsal scutellation in Euscarthmus *led to its exclusion for a time from the tyrant-flycatchers; it was suspected to belong amongst the typical antbirds (Thamnophilidae). Although syringeal morphology soon identified it as tyrannid, it differs from all its likely relatives by building a cup-shaped nest. The **Rufous-sided Pygmy-tyrant** has a puzzling distribution in fire-prone* cerrado *of central Brazil: it is present at a large number of sites, but absent from many others that are ecologically similar. Given the pressures faced by South American grassland in general, this species is classed as Vulnerable.*

[*Euscarthmus rufomarginatus*, Bahia, Brazil. Photo: Arthur Grosset]

In terms of absolute numbers, the ***Noronha Elaenia*** *is one of the rarest of tyrant-flycatchers. It is restricted to the Fernando de Noronha archipelago, off north-east Brazil, where around 500 individuals are thought to survive. The habitat is relatively secure, but the species is classified as Vulnerable in view of the very small size of the population. An upsurge in tourism could have a negative impact on the extent and quality of natural habitat on the islands, and it would seem prudent to establish a terrestrial protected area; the islands already form a marine national park.*

[*Elaenia ridleyana*, Fernando de Noronha Island, Brazil. Photo: Luiz Claudio Marigo]

Subtropical Doradito, the Speckled Mourner (*Laniocera rufescens*) and the Spot-billed Ground-tyrant (*Muscisaxicola maculirostris*), are all more common in other parts of their relatively large ranges.

Similarly, globally non-threatened species with relatively large ranges may nonetheless contain subspecies that are apparently at risk. Two subspecies of the Royal Flycatcher have already been mentioned in preceding paragraphs. Other examples are the Colombian subspecies *bogotensis* of the Bearded Tachuri and the Grenadan subspecies *flaviventris* of Euler's Flycatcher, both of which may already be extinct. In addition, the race *albogriseus* of the Sirystes is threatened by rapid deforestation within its small range in east Panama and adjacent north-west Colombia.

Even species with genuinely large ranges may become threatened if their habitats are destroyed on a large scale. Such may be the case for many of the tyrannids dependent on grassland and savanna and which historically had relatively large ranges. Their habitats are now being eliminated so rapidly that very soon the only remaining fragments will be found within protected areas. Species that may require monitoring are the Suiriri and Chapada Flycatchers, the Rusty-backed Monjita, the Chocolate-vented Tyrant, the Rufous Casiornis and the Ash-throated Casiornis (*Casiornis fuscus*).

Moreover, forest-dependent species have become locally extinct within those parts of their range where deforestation has been especially intense. In Panama, for example, this has been the case in western Chiriquí, where local extinctions have been recorded for the Slaty-capped Flycatcher, the Eye-ringed Flatbill, the Golden-crowned Spadebill, the Rufous Mourner (*Rhytipterna holerythra*) and the Speckled Mourner. The same fate has befallen local populations of the Bronze-olive Pygmy-tyrant and the Rufous-breasted Flycatcher in central Colombia, the Rufous-headed Pygmy-tyrant and the Yellow-margined Flycatcher in south-west Ecuador, and the Southern Bristle-tyrant (*Pogonotriccus eximius*) and the Rufous-sided Pygmy-tyrant in São Paulo, in Brazil.

Despite what appears to be a generally gloomy picture of the fortunes of the Tyrannidae, some members of the family obviously benefit from the degradation and destruction of pristine habitats and, indeed, thrive in human-modified landscapes. These include some of what are now most common and well-known bird species of the Americas. Foremost in this category must be the Great Kiskadee and the Tropical Kingbird, both of which have doubtlessly increased in abundance and range wherever forests have been opened up and irrigation has brought vegetation to semi-arid and arid areas. Couch's Kingbird and the Western Kingbird likewise increased for similar reasons, the latter spreading as human settlements and cultivation brought vegetation and artificial structures to the Great Plains of the USA. Other tyrannids seemingly benefiting from deforestation include the Mottle-backed Elaenia, the Sulphur-bellied Tyrannulet, the Mouse-coloured Tyrannulet, the Common Tody-flycatcher, the Olive-chested and Bran-coloured Flycatchers, the Short-crested Flycatcher and the Apical Flycatcher (*Myiarchus apicalis*). Meanwhile, the Golden-crowned Flycatcher and the Cliff Flycatcher appear to spread along roads, with the latter

Virtually restricted to lowland Atlantic Forest, as it is, the ***Sao Paulo Tyrannulet*** *is listed as Vulnerable. It is commonest at elevations below 400 m, precisely the zone most susceptible to habitat clearance. Indeed, only a tiny proportion of lowland Atlantic Forest remains intact. Nevertheless, this species seems an unlikely candidate for imminent extinction, given that it is fairly common in several protected areas. It still thrives in the forests of eastern Paraguay, including the Mbaracayú Forest Nature Reserve, and southern Brazil, including Iguaçu National Park and the lower slopes of the Serra do Mar.*

[*Phylloscartes paulista*, Carlos Botelho State Park, São Paulo, Brazil. Photo: Edson Endrigo]

*After many specimens were taken by early collectors throughout much of the Andes, the **White-tailed Shrike-tyrant** seemed to vanish. Upon its listing as Vulnerable, searches in several of its old haunts drew a blank. None of the suggested explanations seemed realistic, given that high-Andean habitats are little affected by hunting or habitat degradation. In recent years, there has been a steady increase in reports of the species, from Ecuador to Argentina. It seems to favour semi-arid habitat with tall montane plants, such as* Puya *bomeliads. With its patchy distribution at low densities, it requires careful monitoring.*

also adapting to urban environments as convenient replacements for its natural cliff habitats.

The Grey Monjita forages preferentially in recently burned grasslands in central Brazil, and may be favoured by this management strategy. Similarly, restoration of savanna habitat by prescribed burning caused a reversal in population declines of Eastern Kingbirds in central North America.

During the last century, several tyrant-flycatcher species have apparently spread northwards into the USA and Canada. Although the reasons for this are not well known, the Pacific-slope, Buff-breasted and Grey Flycatchers, the Dusky-capped Flycatcher and the Thick-billed (*Tyrannus crassirostris*) and Western Kingbirds may all have benefited from habitat alteration and/or global warming. The detection of such changes in range and abundance is in large part due to the participants in the USA Breeding Bird Survey, whose systematic sampling efforts are one of the best ways of monitoring bird populations on a large scale. Such schemes are desperately needed in Middle and South America, in order to monitor more accurately the status of at least the threatened species, but it would require a huge input in terms of human and material resources even to begin the kind of capacity-building that would be necessary for such an undertaking. One important step would be to train a larger number of birdwatchers so that they can identify species correctly, for most published information still originates from a relatively small number of observers. The translation of English-language field guides into Spanish and Portuguese must be a high priority. Another important step would be to link conservation researchers, field ornithologists and birdwatchers by means of computers and internet-based interactive software, so that they can quickly share critical information. As an example, the organization Conservation International helped to create two data centres in Mexico, one a national biotic-resources information centre at the National University of Mexico and the other a state-level centre for Chiapas at the Instituto de Historia Natural. Other mapping projects have been undertaken by M. L. Isler and by the Zoological Museum at the University of Copenhagen, in Denmark.

Local, as well as global, action is urgently needed to conserve species and the habitats on which they depend. Local action has to focus on the root causes of habitat destruction and degradation, such as the need of local people for timber, firewood, or pasture for livestock. For instance, wherever forest remnants survive on steep slopes, they should be fenced in to restrict livestock movements to relatively flat areas, thereby both decreasing energy expenditure and increasing milk and meat production of the cattle while saving steep areas from degradation and soil erosion. Once such areas regenerate, they could be used for timber and other forest products in a sustainable way.

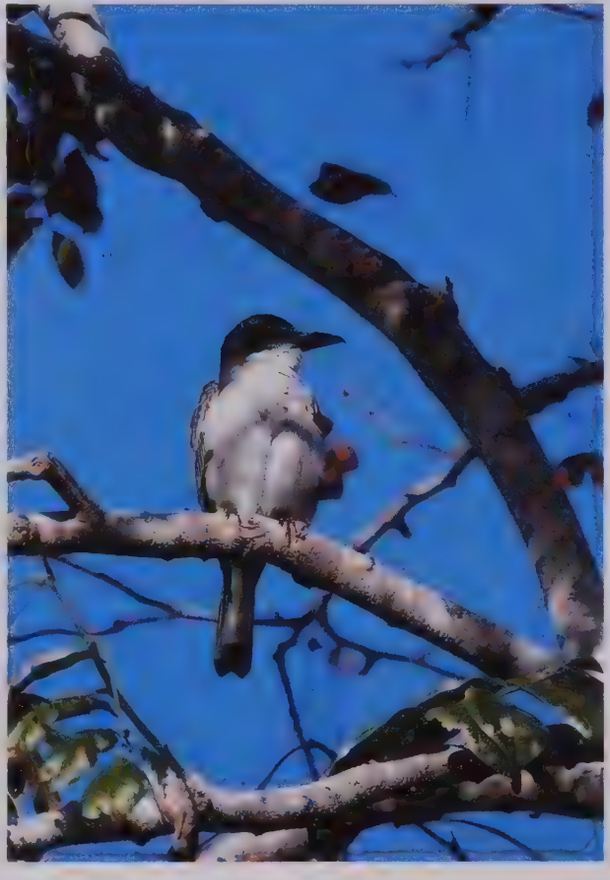
*In recent decades, the damp meadows and grasslands of southern Brazil and northern Argentina have been badly degraded or eliminated altogether by agricultural expansion and extensive planting of non-native trees, such as cultivated pines. These influences have resulted in substantial declines in the population of one extremely elegant tyrant-flycatcher, the **Black-and-white Monjita**. Now classed as Vulnerable, this species also suffers intensive brood-parasitism by cowbirds* (Molothrus), *a genus favoured by the spread of ranchland. Large protected areas encompassing pristine wet* pampas, *bogs and meadows are needed to ensure that this beautiful bird survives.*

[*Xolmis dominicanus*,
Estancia San Juan
Poriahú, Corrientes,
Argentina.
Photo: José & Adriana Calo]

The genus Alectrurus *contains two remarkable tyrant-flycatchers, both listed as Vulnerable. Both are strongly sexually dimorphic, with piebald plumage and spectacular tails in the males, and both are undergoing serious population declines. The range of the* ***Cock-tailed Tyrant*** *is centred on the* cerrado *region of Brazil, whereas the* ***Strange-tailed Tyrant*** *breeds in southern Paraguay and northern Argentina. The former gets its name from the strange fan-shaped tail resembling a miniature rooster's tail. The latter needs no explanation: its hugely elongated, bare-shafted outer-tail feathers are bizarre indeed. In the breeding season, male Strange-tailed Tyrants lose the feathering of their throats, and the exposed skin turns bright orange or red. Males of both these species spend much of the breeding season performing eye-catching aerial displays, and apparently contributing nothing towards parental care. Evidence is increasing that these are both polygynous species (males are simultaneously mated to several females inside their territory). Sadly, both birds are a rare sight in today's man-modified landscapes. Two-thirds of Brazil's* cerrado *grassland have been destroyed, and huge areas of the Paraguayan and Argentine meadows and* pampas *have been converted into plantations, crops and grazing lands. Given this devastation of natural habitats, an effective network of reserves is required to safeguard both of these bizarre, fascinating tyrants.*

[Above: *Alectrurus tricolor*, Paraparau, Beni, Bolivia. Photo: Joe Tobias.

Below: *Alectrurus risora*, Corrientes, Argentina. Photo: Darío Podestá]



*The diminutive **Fork-tailed Pygmy-tyrant** is an aberrant member of its genus from the Atlantic Forest of south-eastern Brazil. It has a forked tail with pale tips (and only 10 rectrices) and a strange, all-buffy head. Its fondness for stands of bamboo probably explains its very patchy distribution. Species that rely on bamboo have a special conservation challenge, because bamboo tends to thrive, then, after flowering, die out simultaneously over large areas. This means that larger blocks of protected forest are required to safeguard locally distributed bamboo specialists. For this reason, and the paucity of sites from which it is known, this rarely observed pygmy-tyrant is listed as Endangered.*

[*Hemitriccus furcatus*, Ubatuba, São Paulo, Brazil. Photo: Edson Endrigo]

In Peru, for example, several small and widely separated *Polylepis* woodlands on which the Ash-breasted Tit-tyrant, an Endangered tyrannid, depends are found around Abra Málaga, in Cuzco; these woodlands are continuously degraded by timber removal, cattle grazing and fires, but recent conservation projects and public-awareness campaigns have accomplished a slowdown in the exploitation of the timber. Often, local involvement of this kind is indispensable, as many critically important sites are within densely populated areas with rapid human population growth. For example, while many reserves still suffer from the impacts caused by local inhabitants trying to eke out a living, a conservation organization in north-east Brazil, called Associação Nordeste, has attempted to link conservation with the interests of the human community living near the Pedra Talhada State Park, in Alagoas. This reserve protects one of the last remaining Atlantic Forest tracts in the state, as well as the globally threatened Alagoas Tyrannulet and Buff-breasted Tody-tyrant. Significant areas in Pedra Talhada are now being reforested with native trees, and protection is enforced by guards and welcomed by the local community.

Greater human resources are urgently required in order to involve local communities in the protection of their immediate environments and to give reserve-managers the necessary means to protect their reserves from outside intrusions. The immediate goal must be to save critical sites from complete destruction, so as to prevent the demise of, for instance, the Minas Gerais Tyrannulet and the Piura Chat-tyrant (*Ochthoeca piurae*), the latter so far not known to occur within any protected area. The long-term survival of many endangered populations, however, will also depend on the enlarging of protected areas through reforestation and connecting them by means of protected "corridors". Nowadays, the local eradication of introduced predators and herbivores on small islands is feasible, although the removal of "harmful" species, such as the Common Starling, on a continental scale is a very different matter.

If habitat loss and species extinctions are to be halted, local action must be backed up by global initiatives. The rapid growth in the human population is a major concern, one requiring serious attention from both political leaders and the general public, yet there is an almost universal reluctance even to discuss this issue, let alone to tackle it. Further, consumption patterns and the exploitation of natural resources must be changed to sustainable levels. As an example, the undiminished craving in the developed world for soya beans in order to feed livestock has led to the widespread clearing of forests and other critical habitats all over South America, even within protected areas. Likewise, most tropical hardwoods utilized in the developed world still do not originate from sustainable sources. Much habitat clearance has

*The **Giant Kingbird** is another Endangered tyrannid. It has disappeared from its previous haunts in the Bahamas and the Turks and Caicos Islands, and is now very rare and local in Cuba, probably as a result of deforestation. It favours pine forest and woodland, habitats that are continuously being cleared and converted to agriculture, or logged for timber. Few data are available regarding its ecological requirements, and field research is urgently needed for developing a programme of effective conservation action.*

[*Tyrannus cubensis*, Najasa, Cuba. Photo: Roy de Haas/ AGAMI]

*First collected in the forests of Santa Catarina, south Brazil, in 1929, **Kaempfer's Tody-tyrant** "disappeared" for over 60 years before it was rediscovered at the type locality in 1991. Although it survives here in small numbers, and at two further sites, available evidence suggests that its total range is very small and its habitat is subject to constant pressure. As a result, it is considered Endangered. More survey work is required in order to assess its true status and distribution. The Volta Velha reserve requires strict protection and, if possible, expansion to include further tracts of suitable habitat.*

[*Hemitriccus kaempferi*, Volta Velha Reserve, Itapoá, Santa Catarina, Brazil. Photo: Dante Buzzetti]

also been the result of government incentives and development schemes, which are often economically unsound but are supported by special-interest groups within business and government. State and national laws, government regulations, the allocation of resources by both government and businesses, and international treaties regulating finance and trade all have a direct influence on the way in which environmental resources are used, and thus on habitats on which wildlife birds depends. Many ecologists and conservationists are realizing more and more that national and global laws, regulations and treaties have direct impacts on local habitats and populations, and that to ignore these causal linkages is to render long-term conservation efforts ineffective and ultimately useless.

Basically, economic rules that reward environmental destruction with financial benefits and punish environmental protection with competitive disadvantages will lead to the exploitation of all natural resources, until the point when they become so rare and valuable that their protection is worth more than their destruction. For example, some privately run reserves now earn more money from ecotourism than they would make from cutting down the forest. If we wait for that point to arrive, however, most natural areas will by then have disappeared and many species will have become extinct. Moreover, even if the protection of natural habitats may render a greater economic benefit, such benefits often cannot be reaped because the resources required to build the initial infrastructure for a successful ecotourism enterprise simply do not exist. In other words, the knowledge and the money needed for the wise and sustainable use of the natural environment are lacking.

If the future of the globally threatened Tyrannidae and that of all other wildlife species is to be secured, it is vital that environmentally sustainable long-term planning is adopted into political and economic thinking, decision-making and administration at all levels of government and business.

*Only two tyrant-flycatchers are listed as Critical, one of which is the **Minas Gerais Tyrannulet**. This poorly known species was discovered in semi-deciduous forests along the River São Francisco, in Minas Gerais, Brazil, in 1926. Although it was found again at the same site in 1977, it has disappeared there during subsequent years, as suitable habitat has been destroyed. Fortunately, small populations do survive at other sites, including the newly established Cavernas do Peruaçu National Park. Strict protection of this area is a priority, given the severe pressure on remnant woodland and emergent trees, for both timber and new agricultural land.*

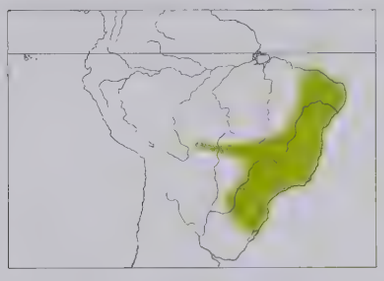
PLATE 16

inches 2



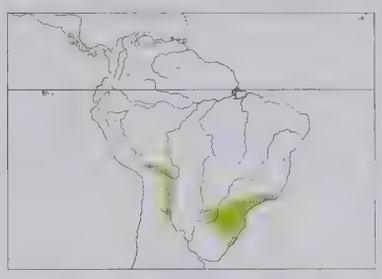
cm 5

Subfamily ELAENIINAE
Tribe ELAENIINI
Genus *PHYLLOMYIAS* Cabanis & Heine, 1859

1. Planalto Tyrannulet
Phyllomyias fasciatus

French: Tyranneau fascié **German**: Planaltokleintyrann **Spanish**: Mosquerito Oliváceo

Taxonomy. *P[ipra] fasciata* Thunberg, 1822, Jaguacara, Bahia, Brazil.
Genus as presently constituted may be polyphyletic; objective phylogenetic analysis, using molecular characters as well as anatomical ones, is required in order to define generic limits. Anatomical evidence suggests that present species may be closest to *P. griseocapilla* and *P. griseiceps* and that all three perhaps unrelated to others of genus, some or all of which possibly better placed in resurrected genus *Tyranniscus*. Three subspecies recognized.
Subspecies and Distribution.
P. f. cearae Hellmayr, 1927 - NE Brazil (Ceará and Rio Grande do Norte S to Sergipe).
P. f. fasciatus (Thunberg, 1822) - E Brazil (Maranhão and W Bahia S to SE Mato Grosso and S Goiás) and W & NE Bolivia.
P. f. brevirostris (Spix, 1825) - SE Brazil, E Paraguay and NE Argentina.

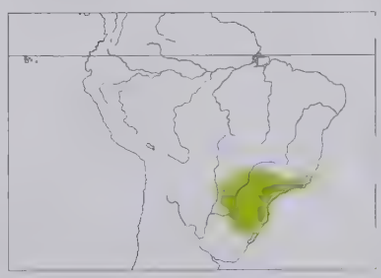


Descriptive notes. 11-11·5 cm. Dull, very small-billed tyrannulet. Nominate race is greyish-olive to brownish-olive above, darker grey on crown; supraloral stripe and eyering whitish; wings dusky, two somewhat indistinct wingbars and edges of flight-feathers pale olive to whitish; tail dusky; throat and lower face whitish, underparts yellow, washed olive on breast and sides; iris brown; bill small and rounded, blackish; legs grey. Sexes alike. Juvenile resembles adult. Races differ in size and in colour intensity: *brevirostris* is somewhat larger and darker olive above than nominate, wingbars and edges of remiges pale olive, throat less extensively white, underparts darker yellow; *cearae* is similar to previous but duller, less yellowish, with darker brown crown, paler yellow underparts. Voice. Calls frequently, a soft, leisurely whistle usually of three syllables of same length but gently descending, "pee-pew-puuit" or "pee, pew, pew," also "eweet, ewwet, eweet"; sometimes grades into longer song, a jumble of notes alternating loud and soft, and including clear whistles, "dliewt..., ra-ewt".
Habitat. Humid tropical evergreen forest, less often semi-deciduous woodland and gallery forest; sea-level to 1800 m, most frequent at 500-800 m.
Food and Feeding. Insects, also small fruits. Forages singly or in pairs, rather high in canopy, tail held partially cocked; often with mixed-species flocks. Perch-gleans, also makes short sallies to hover-glean items.
Breeding. Sept-Feb, nest found in Nov, in SE Brazil (Rio Grande do Sul). Group display involves 3-4 or more individuals nervously hopping through vegetation, occasionally singing. Nest cup-shaped, 6·6 cm across, inner diameter 4·1 cm, woven of moss and fungal hyphae (of *Marasmius*), covered inside and outside with flakes of lichen, placed 7 m up in four-way crotch of outer branch, surrounding branches also covered with lichen and moss. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. Apparently present only in austral summer (Sept-Mar/Apr) in SE Brazil (Rio Grande do Sul), suggesting N movement by populations from extreme S, but confirmation needed.
Status and Conservation. Not globally threatened. Fairly common to locally common in much of its relatively large range. Occurs in several protected areas, including Noel Kempff Mercado National Park, in Bolivia, and Serra da Canastra National Park and Patrimônio Natural do Caraça Special Reserve (Minas Gerais) and Itatiaia and Aparados da Serra National Parks, in Brazil.
Bibliography. Bates & Parker (1998), Bates *et al.* (1998), Belton (1985), Brooks *et al.* (1993), Canevari *et al.* (1991), Clay, Tobias *et al.* (1998), Cory & Hellmayr (1927), Develey (2004), Dubs (1992), Ferreira de Vasconcelos (2001), Hayes (1995), Lanyon (1988b), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Parker *et al.* (1991), de la Peña (1988), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977).

2. Rough-legged Tyrannulet
Phyllomyias burmeisteri

French: Tyranneau pattu **German**: Burmeisterkleintyrann **Spanish**: Mosquerito de Burmeister
Other common names: White-fronted Tyrannulet (*leucogonys*); Zeledon's Tyrannulet (*zeledoni*)

Taxonomy. *P[hyllomyias] Burmeisteri* Cabanis and Heine, 1859, Rio de Janeiro, Brazil.
Genus as presently constituted may be polyphyletic; objective phylogenetic analysis, using molecular characters as well as anatomical ones, is required in order to define generic limits. Anatomical evidence suggests that *P. fasciatus*, *P. griseocapilla* and *P. griseiceps* may be unrelated to others of genus, some or all of which possibly better placed in resurrected genus *Tyranniscus*. Present species was for long treated in its own genus, *Acrochordopus*, because of distinctively serrated tarsus, but tarsal scutellation now known to be unreliable as a generic character in the family. Nominate race and *zeledoni* sometimes considered to represent two distinct species, with the other four ("*leucogonys* group") forming a third species, but biological information about all populations remains scarce, and vocal and genetic relationships not yet studied; investigation needed especially in area of possible contact between *leucogonys* and nominate in S Peru and N Bolivia. Six subspecies recognized.
Subspecies and Distribution.
P. b. zeledoni (Lawrence, 1869) - Costa Rica and W Panama.
P. b. wetmorei (Aveledo & Pons, 1953) - Sierra de Perijá, in W Venezuela.
P. b. viridiceps (J. T. Zimmer & Phelps, Sr, 1944) - mountains of N Venezuela.
P. b. bunites (Wetmore & Phelps, Jr, 1956) - Chimantá-tepui, in SE Bolívar (E Venezuela).
P. b. leucogonys (P. L. Sclater & Salvin, 1871) - E Andes from Colombia S to SE Peru.
P. b. burmeisteri Cabanis & Heine, 1859 - E Andes of Bolivia and N Argentina, also locally from E & SE Brazil to SE Paraguay.



Descriptive notes. 11-11·5 cm; 11 g. Nominate race is olive above, crown slightly darker olive, forehead olive, narrow loral streak white; wings dusky, two wingbars and edges of flight-feathers pale olive-yellow to yellow; tail dusky olive; throat white, lower face grizzled whitish, underparts yellow, washed or flammulated with olive on breast and sides; iris dirty whitish, pale sandy brown or light reddish-brown; bill black, basal half of lower mandible whitish to pale flesh-coloured; legs greyish-black. Sexes alike. Juvenile resembles adult. Race *zeledoni* has crown slaty grey, narrow supercilium and eyering white, white of lores connecting across forehead; *leucogonys* differs from previous in larger bill, duller green back, slightly paler yellow underparts with less prominent flammulations; *wetmorei* is darker overall; *bunites* has tiny bill, dark grey of crown extends to hindneck; *viridiceps* has slate-grey forehead, rest of crown olive-green. Voice. Easily heard, high-pitched, repeated whistles, "psee-psee-psee-psee", on same pitch or falling slightly near end, also described as descending series of c. 6 loud "éeeet" or monotonously repeated "pseet" notes timed at 35-75 per minute (nominate race); also (*zeledoni* and "*leucogonys* group") a continuous series of double notes, "tzee-yeep tzee-yeep tsee-yeep" and single "péééza" at intervals of 2-3 seconds.
Habitat. Humid tropical and upper tropical evergreen forest, sometimes venturing to edges and older second growth. At 900-1850 m in Costa Rica and Panama, 475-1800 m in Colombia and Venezuela, 600-1500 m in Ecuador, and 750-1600 m in SE Peru; breeds in mountains in SE Brazil.
Food and Feeding. Arthropods and small berries. Forages alone or in pairs, sometimes with mixed-species flocks, mainly in middle or upper levels of vegetation, but may venture quite low when foraging alone. More sluggish than many tyrannulets, perching with horizontal posture for many seconds, occasionally flicking wings while perched, and making short upward sallies to hover-glean, or moving with short flights to new perch; also perch-gleans from branch or leaves.
Breeding. Birds with enlarged gonads in Oct and Dec in Brazil (Rio Grande do Sul). Nest cup-shaped, internal diameter 5-6 cm, external diameter 9-10 cm; one was placed 12 m up on outer, horizontal limb (Panama). No further information.
Movements. Apparently resident in most of range. In SE Brazil, present in Rio de Janeiro only in austral winter, suggesting either vertical migration from Serra do Mar or movement N by individuals from extreme S; latter perhaps more likely, as recorded in Rio Grande do Sul only during Oct-May.
Status and Conservation. Not globally threatened. Very uncommon to rare, and local, in Venezuela; uncommon to locally common elsewhere; perhaps often overlooked. Occurs in many protected areas throughout range, e.g. present in at least three national parks in SE Brazil.
Bibliography. Anon. (1998a), Belton (1985), Brooks *et al.* (1993), Canevari *et al.* (1991), Chapman (1917c, 1926), Christian (2001), Clay, Tobias *et al.* (1998), Cory & Hellmayr (1927), Cracraft (1985), Davis (1986), Fjeldså & Maijer (1996), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Lowen *et al.* (1996), Miller (1963), Narosky & Salvador (1998), Parker *et al.* (1991), de la Peña (1988), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins & Ridgely (1990), do Rosário (1996), Sick (1993, 1997), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Strewe & Navarro (2004), Traylor (1977), Walker *et al.* (2003), Weske (1972), Wetmore (1972), Zimmer (1941c).

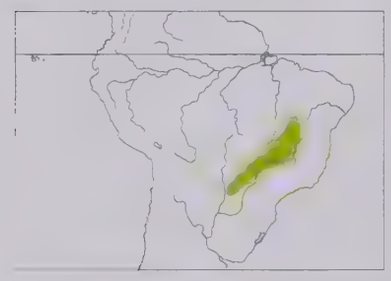
3. Greenish Tyrannulet
Phyllomyias virescens

French: Tyranneau verdin **German**: Grünrücken-Kleintyrann **Spanish**: Mosquerito Verdoso

Taxonomy. *Muscicapa virescens* Temminck, 1824, Curytiba, Paraná, Brazil.
Genus as presently constituted may be polyphyletic; objective phylogenetic analysis, using molecular characters as well as anatomical ones, is required in order to define generic limits. Anatomical evidence suggests that *P. fasciatus*, *P. griseocapilla* and *P. griseiceps* may be unrelated to others of genus, some or all of which possibly better placed in resurrected genus *Tyranniscus*. Present species formerly placed along with *P. sclateri* in a separate genus, *Xanthomyias*. Appears to form a superspecies with *P. reiseri* and *P. urichi*; all were for long considered conspecific, but differences in morphology (plumage pattern, wing and tail proportions), degree of sexual dimorphism, habitat and voice evident. Has been suggested that *P. sclateri* also belongs in this group. Monotypic.
Distribution. SE Brazil (S Mato Grosso do Sul E to S Minas Gerais and Espírito Santo, S to C Rio Grande do Sul), SE Paraguay, and extreme NE Argentina.

Descriptive notes. 12 cm; 10-12 g. A bright green tyrannulet, somewhat longer-tailed than its close relatives. Is bright olive above from forehead and orbital area to rump; wings dusky, two wingbars and edges of flight-feathers pale yellowish; tail dusky; throat and lower face whitish, underparts yellow, faintly streaked olive on breast and sides; iris brown, bill small and rounded, brown to blackish, base of lower mandible brownish-white; legs medium to dark grey. Distinguished from similar *P. reiseri* by slightly larger size, olive ear-coverts, in the hand also by longer wing (male 58-65 mm, female 55-62 mm), longer tail (male 54-64 mm,

On following pages: 4. Reiser's Tyrannulet (*Phyllomyias reiseri*); 5. Urich's Tyrannulet (*Phyllomyias urichi*); 6. Sclater's Tyrannulet (*Phyllomyias sclateri*); 7. Grey-capped Tyrannulet (*Phyllomyias griseocapilla*); 8. Sooty-headed Tyrannulet (*Phyllomyias griseiceps*); 9. Plumbeous-crowned Tyrannulet (*Phyllomyias plumbeiceps*); 10. Black-capped Tyrannulet (*Phyllomyias nigrocapillus*); 11. Ashy-headed Tyrannulet (*Phyllomyias cinereiceps*); 12. Tawny-rumped Tyrannulet (*Phyllomyias uropygialis*); 13. Yellow-crowned Tyrannulet (*Tyrannulus elatus*).



female 51-62 mm). Sexes alike. Juvenile resembles adult. VOICE. Rapid series of notes, begins with staccato "chk" notes rising rapidly in pitch, then becoming longer sounds that fall and slow slightly at end, "chk-chk-chk-chk-chk-cheee-eeee-eeee-eeee-chu-choo".
Habitat. Humid tropical and upper tropical evergreen forest and edges, also secondary growth; to 1000 m.
Food and Feeding. Poorly known. Forages at all heights in interior and edges of forest, sometimes within 2 m of ground.
Breeding. Oct in Brazil (Rio Grande do Sul); nest found in Nov in Argentina. Nest purse-shaped, with a side entrance 3 cm wide, made entirely of mosses, suspended from branch within 1 m of ground in small arroyo. Clutch 2 eggs; incubation and fledging periods not recorded. No further information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Not well known; usually uncommon. Numbers may have declined towards S edge of range. Occurs in several national parks and other protected areas in all three countries which it inhabits. Apparently not entirely dependent on undisturbed forest; found also in secondary vegetation and edge habitat.
Bibliography. Belton (1985), Brooks *et al.* (1993), Canevari *et al.* (1991), Castelino & Saibene (1989), Clay, Tobias *et al.* (1998), Cory & Hellmayr (1927), Darrieu (1987), Dubs (1992), Hayes (1995), Lowen *et al.* (1996), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Pacheco *et al.* (1996), de la Peña (1988), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), da Silva (1996a), Stotz (1990b), Stotz *et al.* (1996), Teixeira *et al.* (1991), Traylor (1982), Willis & Oniki (1991), Zimmer (1955b).

4. Reiser's Tyrannulet

Phyllomyias reiseri

French: Tyranneau de Reiser **German**: Reiserkleintyrann **Spanish**: Mosquerito de Reiser

Taxonomy. *Phyllomyias reiseri* Hellmayr, 1905, Grotão, Piauí, Brazil.
Genus as presently constituted may be polyphyletic; objective phylogenetic analysis, using molecular characters as well as anatomical ones, is required in order to define generic limits. Anatomical evidence suggests that *P. fasciatus*, *P. griseocapilla* and *P. griseiceps* may be unrelated to others of genus, some or all of which possibly better placed in resurrected genus *Tyranniscus*. Appears to form a superspecies with *P. virescens* and *P. urichi*, and probably closest to latter; all were for long considered conspecific, but differences in morphology (plumage pattern, wing and tail proportions), degree of sexual dimorphism, habitat and voice evident. Has been suggested that *P. sclateri* also belongs in this group. Monotypic.
Distribution. EC Brazil (S Piauí to N Minas Gerais, S Goiás, Distrito Federal, E Mato Grosso do Sul) and EC Paraguay (Concepción).

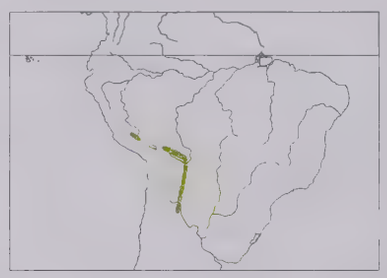
Descriptive notes. 11·5 cm; 7-8 g. Bright yellow-green tyrannulet. Plumage is bright olive from forehead to rump, crown feathers faintly tipped greyish; lores, narrow supercilium and cheeks yellowish-white; wings dusky, two broad wingbars and edges of flight-feathers pale yellowish; tail dusky olive; throat and lower face whitish, underparts pale yellow, faintly streaked or washed with olive on breast and sides; iris pale brown; bill small and rounded, blackish, lower mandible pinkish to white with black tip; legs grey. Best distinguished from very similar *P. virescens* by slightly smaller size, usually yellowish ear-coverts without dusky or olive tips, in the hand also by shorter wing (male 54-59 mm, female 52-58 mm), shorter tail (male 49-58 mm, female 47-54 mm). Sexes alike. Juvenile resembles adult. VOICE. A series of rough, liquid notes moving down the scale, "briu-briu-briu-briu-briu-briu-briu".
Habitat. Tropical dry forest and gallery forest.
Food and Feeding. Little known. Apparently forages in canopy and along edges of dry to semi-deciduous forest trees.
Breeding. No data.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Poorly known. Uncommon and very local. Known from c. 15 widely dispersed localities in interior E Brazil and NE Paraguay, where it is found in gallery forest in the *cerrado* region and in subtropical, dry deciduous forests (N Minas Gerais). Recorded in Cavernas do Peruaçu National Park (Minas Gerais), in Brazil. Severe degradation, fragmentation and destruction of *cerrado* habitat has already taken place; if habitat destruction continues unabated, the conservation status of this species may have to be upgraded to that of Near-threatened.
Bibliography. Belton (1985), Clay, Tobias *et al.* (1998), Collar *et al.* (1994), Cory & Hellmayr (1927), Forrester (1993), Green (1997b), Hayes (1995), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Sick (1993, 1997), da Silva (1996a), Stotz (1990a), Stotz *et al.* (1996), Teixeira *et al.* (1991), Traylor (1982), Willis & Oniki (1991), Zimmer (1955b).

5. Urich's Tyrannulet

Phyllomyias urichi

French: Tyranneau d'Urich **German**: Urichkleintyrann **Spanish**: Mosquerito de Paria

Taxonomy. *Mecocerculus urichi* Chapman, 1899, Quebrada Seca, Sucre, Venezuela.
Genus as presently constituted may be polyphyletic; objective phylogenetic analysis, using molecular characters as well as anatomical ones, is required in order to define generic limits. Anatomical evidence suggests that *P. fasciatus*, *P. griseocapilla* and *P. griseiceps* may be unrelated to others of genus, some or all of which possibly better placed in resurrected genus *Tyranniscus*. Appears to form a superspecies with *P. virescens* and *P. reiseri*, and probably closest to latter; all were for long considered conspecific, but differences in morphology (plumage pattern, wing and tail proportions), degree of sexual dimorphism and habitat evident. Has been suggested that *P. sclateri* also belongs in this group. Monotypic.
Distribution. NE Venezuela: mountains in NE Anzoátegui, Sucre and N Monagas.
Descriptive notes. 11·5 cm. Plumage is bright olive from forehead to rump, crown feathers slightly tipped dusky to greyish; lores and narrow supercilium whitish; wings dusky, two broad wingbars and edges of flight-feathers pale yellowish-white; tail dusky olive; throat and lower face whitish, underparts pale yellow, faintly streaked olive on breast and sides; iris brown; bill small and rounded, blackish, lower mandible paler; legs grey. Perhaps indistinguishable in the field from *P. reiseri*. Sexes alike. Juvenile undescribed. VOICE. Not documented.



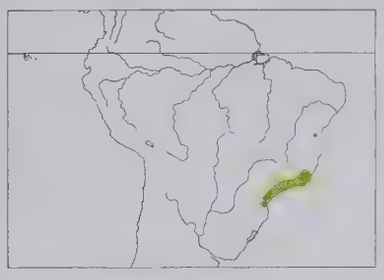
Habitat. Humid upper tropical montane forest; typically at 900-1100 m, occasionally down to 800 m.
Food and Feeding. Almost unknown. Observed to forage at forest edge, at mid-height in a tree 10-15 m tall; gleaned insect prey from underside of leaves while moving actively from branch to branch; tail not cocked.
Breeding. Unknown.
Movements. Presumed resident.
Status and Conservation. ENDANGERED. Rare. Range very small, c. 1000 km², and global population estimated at a few thousand individuals. Specimens from several sites in Cordillera de Caripe, but few (if any) recent observations; a recent sight record from Cerro Humo, in Paria Peninsula National Park. Also recorded in Cuevo del Guácharo National Park (N Monagas), recently expanded to include a further 500 km² of largely undisturbed forest. Habitat being rapidly destroyed owing to changing agricultural practices and conversion to plantations. Widespread clearance for agriculture and pasture has taken place in Cordillera de Caripe, even within protected areas; habitat in Cuevo del Guácharo National Park adversely affected by understorey removal for coffee-growing, illegal clearance and fires, and slopes of Cerro Negro now largely bare, with the more obvious "forested" patches being shade coffee plantations and only the mountaintop still covered in true forest. Conversion to commercial crops and plantations (coffee, mango, banana, orange, lemon) has occurred in remainder of Serranía de Turumiquire, but extensive forested areas remain. On Cerro Humo, increases in cash-crop agriculture, especially the cultivation of "ocumo blanco" (*Colocasia*), since middle to late 1980s, have resulted in uncontrolled burning and forest degradation. Much fieldwork is required in order to determine this little-known species' precise requirements and to set up effective programmes for its conservation.
Bibliography. Cory & Hellmayr (1927), Cracraft (1985), Gabaldón (1992), Hilty (2003), Kirwan & Sharpe (1999), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1950), Ridgely & Tudor (1994), da Silva (1996a), Stattersfield & Capper (2000), Stotz (1990a), Stotz *et al.* (1996), Teixeira *et al.* (1991), Traylor (1982), Zimmer (1955b).

6. Sclater's Tyrannulet

Phyllomyias sclateri

French: Tyranneau de Sclater **German**: Graubrust-Kleintyrann **Spanish**: Mosquerito de Sclater

Taxonomy. *Phyllomyias sclateri* Berlepsch, 1901, Bueyes, Santa Cruz, Bolivia.
Genus as presently constituted may be polyphyletic; objective phylogenetic analysis, using molecular characters as well as anatomical ones, is required in order to define generic limits. Anatomical evidence suggests that *P. fasciatus*, *P. griseocapilla* and *P. griseiceps* may be unrelated to others of genus, some or all of which possibly better placed in resurrected genus *Tyranniscus*. Present species formerly placed in a genus *Xanthomyias* along with *P. virescens*; has been suggested that it may belong in a superspecies formed by latter, *P. reiseri* and *P. urichi*. Proposed taxon *T. australis* is regarded as a synonym of present species. Two subspecies recognized.
Subspecies and Distribution.
P. s. subtropicalis (Chapman, 1919) - E Andes of SE Peru (Cuzco).
P. s. sclateri Berlepsch, 1901 - E Andes of Bolivia (La Paz S to Tarija) and NW Argentina (Jujuy S to Tucumán).



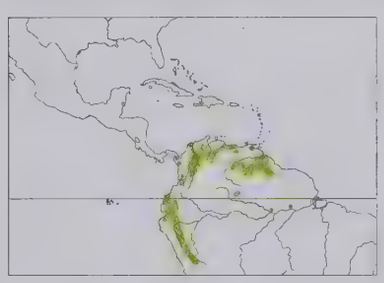
Descriptive notes. 11·5 cm. Is dull olive-green above, slightly more greyish on crown; lores and short supercilium whitish; wings dusky, two broad wingbars and conspicuous edges of flight-feathers very pale yellow to whitish; tail dusky olive; throat greyish-white, lower face grizzled whitish, breast pale grey, grading to pale yellowish on flanks and belly; iris brown; bill small and rounded, blackish, lower mandible slightly paler at base; legs grey. Sexes alike. Juvenile resembles adult. Race *subtropicalis* is more greyish-green above, supercilium wider, crown more pure grey, edges of flight-feathers white, underparts very pale, virtually lacking yellow suffusion. VOICE. Rapid series of harsh, sputtering notes.
Habitat. Humid montane forest and cloudforest; found also at edges, and often in clearings and lighter woodlands dominated by alder (*Alnus*). At 1500-2400 m in Peru and N Bolivia, and 400-1500 m in Bolivia and Argentina.
Food and Feeding. Insects. Forages actively in middle and upper levels of mossy forest, sometimes alone, often with mixed tanager (Thraupidae) flocks. Perches horizontally, and rapidly flicks wings while perch-gleaning from branches and leaves.
Breeding. Juvenile in Nov in Bolivia. Nest an open cup of twigs, lined with feathers, placed in epiphytes on elevated tree branch (Argentina). Clutch size and other details not documented.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Rare to fairly common; perhaps often overlooked. Regularly observed in Machu Picchu Historical Sanctuary (from near base, e.g. along lower part of Puente Ruinas-Machu Picchu Ruins road), in Peru; occurs also in Madidi National Park and Pilón Lajas Biosphere Reserve, in Bolivia.
Bibliography. Blendinger (1998), Bostwick & Zyskowski (2001), Canevari *et al.* (1991), Chapman (1917c, 1926), Cory & Hellmayr (1927), Cracraft (1985), Dinelli (1918), Fjeldså & Krabbe (1990), Hennessey, Herzog, Kessler & Robinson (2003), Hennessey, Herzog & Sagot (2003), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Olrog (1963, 1984), de la Peña (1988), Remsen & Traylor (1989), Ridgely & Tudor (1994), da Silva (1996a), Stotz *et al.* (1996), Traylor (1977, 1982), Walker (2001), Weske (1972), Zimmer (1941b).

7. Grey-capped Tyrannulet

Phyllomyias griseocapilla

French: Tyranneau à tête grise **Spanish**: Mosquerito Coronigrís
German: Graukappen-Kleintyrann

Taxonomy. *Phyllomyias griseocapilla* P. L. Sclater, 1862, presumably Rio de Janeiro, Brazil.
Genus as presently constituted may be polyphyletic; objective phylogenetic analysis, using molecular characters as well as anatomical ones, is required in order to define generic limits. Anatomical evidence suggests that present species may be closest to *P. fasciatus* and *P. griseiceps* and that all three perhaps unrelated to others of genus, some or all of which possibly better placed in resurrected genus *Tyranniscus*. Present species has been placed by some authors in genus *Oreotriccus*, which originally contained only *P. plumbeiceps*, but considered not allied to latter. Monotypic.
Distribution. E Brazil in SC Bahia and from Minas Gerais and Espírito Santo S to Santa Catarina.



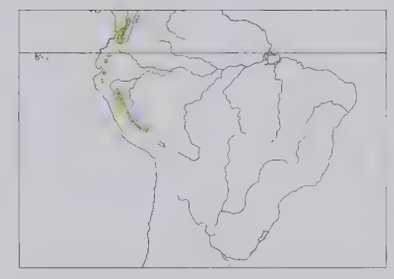
Descriptive notes. 11 cm. Plumage is bright olive-green above, slate-grey on crown and nape; narrow white loral spot, white area around eye; wings dusky, two wingbars and conspicuous edges of wing-coverts and flight-feathers bright yellow; tail dusky olive; lower face pale grey, throat greyish-white; breast pale grey, grading to whitish belly, flanks bright yellow-green; iris brown; bill small and rounded, blackish; legs grey. Sexes alike. Juvenile undescribed. Voice. A pair or short series of softly whistled "wheeuw" notes.
Habitat. Humid upper tropical forest and forest edges, including shrubby clearings and dense second growth; usually 750-1850 m, locally down to sea-level.
Food and Feeding. Insects; berries and small fruit, especially of mistletoe (Loranthaceae), also frequently eaten. Forages singly or in pairs, occasionally with mixed-species flocks, at lower levels than most of its congeners. Perch-gleans and hover-gleans.
Breeding. No information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Atlantic Forest Mountains EBA. Uncommon to relatively common, but patchily distributed; perhaps commoner at upper levels in the Serra do Mar and Serra de Paranapiacaba. Occurs in several protected areas, including Itatiaia National Park, Augusto Ruschi Biological Reserve and Intervales State Park; in the last-mentioned, although it was rarely observed around the Saibadela Research Station, it is more abundant at upper elevations within the park. Even within protected areas, forest areas continue to be lost through agricultural conversion, as well as mining, urbanization and industrialization, coupled with associated road-building.
Bibliography. Aleixo & Galetti (1997), Clay, Tobias *et al.* (1998), Collar *et al.* (1994), Cory & Hellmayr (1927), Develey (2004), Forrester (1993), Lanyon (1988b), Meyer de Schauensee (1982), Naka *et al.* (2000), Pacheco & Whitney (1995), Parker *et al.* (1996), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Traylor (1977), Venturini *et al.* (2001), Zimmer (1955b).

8. Sooty-headed Tyrannulet

Phyllomyias griseiceps

French: Tyranneau nain **German**: Rußkappen-Kleintyrann **Spanish**: Mosquerito Cabecigrís
Other common names: Crested/Sooty-crested Tyrannulet

Taxonomy. *Tyranniscus griseiceps* P. L. Sclater and Salvin, 1871, Pallatanga, Chimborazo and Babahoyo, Los Ríos, Ecuador.
Genus as presently constituted may be polyphyletic; objective phylogenetic analysis, using molecular characters as well as anatomical ones, is required in order to define generic limits. Anatomical evidence suggests that present species may be closest to *P. fasciatus* and *P. griseocapilla* and that all three perhaps unrelated to others of genus, some or all of which possibly better placed in resurrected genus *Tyranniscus*. Proposed races *cristatus* (Panama, N Colombia, N Venezuela), *caucae* (middle and upper Cauca Valley, in Colombia) and *pallidiceps* (SE Venezuela, S Guyana, N Amazonian Brazil, E Peru), described on basis of differences in length and colour of crown feathers and in wing length, considered unwarranted; variation in these characters at least as great among individuals from same regions as it is across huge geographical areas. Monotypic.
Distribution. Locally in E Panama, Colombia, Venezuela, Guyana, W & E Ecuador, E Peru (S to Ayacucho), and N Brazil (left bank of lower R Amazon).



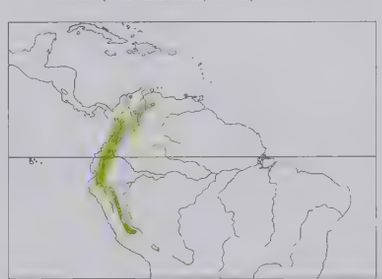
Descriptive notes. 10 cm; 8 g. A tiny, dull tyrannulet often showing slightly bushy crest. Plumage is dull greyish-olive above, darker greyish to blackish on crown, crown feathers of many individuals slightly elongated to form ill-defined crest; loral spot and narrow supercilium white, face grizzled whitish, narrow dark grey spot behind eye; wings dusky, indistinct narrow whitish edgings of wing-coverts and inner remiges (no wingbars); tail dusky; throat greyish-white, breast and flanks pale olive, grading to bright yellow on belly; iris dark brown; bill very small and rounded, black; legs black. Sexes alike. Juvenile undescribed. Voice. Song, often from exposed perch, an emphatic phrase of clear, short whistled notes, first one stressed, "whip, whip-di-irip" or "whit, whit-wheeu"; song may vary somewhat geographically, in Bolivia said to end with a rolling, descending trill.
Habitat. Humid tropical and upper tropical evergreen forest regions, occurring mainly in forest borders, clearings with scattered trees, partially cleared landscapes, also dry white-sand forests, plantations, even dry woodlots; generally not in primary forest. Mostly below 1200 m, occasionally to 1800 m; in lowlands, to 460 m, in E Venezuela, Guyana and Brazil.
Food and Feeding. Insects; also small fruits and berries. Forages in middle and upper canopy, usually alone except when visiting fruiting trees; occasionally with mixed-species flocks. Flits actively while perch-gleaning and making short upward sallies to hover-glean from leaves.
Breeding. Nest found in Feb in NW Ecuador, a small cup covered with lichen, in crotch of small branch 13 m above ground. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Rare to locally common, but probably often overlooked. Numerous in Tayrona National Park, in Colombia, and Río Palenque Science Centre and Tinalandia Private Reserve, both in NW Ecuador; occurs also in several other protected areas, including, among others, Darién National Park, in Panama, and Northwest Peru Biosphere Reserve, in Peru. Because of its relatively large range and tolerance of converted habitat, this species is not considered to be at any risk.
Bibliography. Anon. (1998a), Chapman (1917c, 1926), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Delgado (1985), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Miller (1963), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins & Ridgely (1990), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Traylor (1977), Walker *et al.* (2003), Wetmore (1972), Weske (1972), Zimmer (1930, 1941b).

9. Plumbeous-crowned Tyrannulet

Phyllomyias plumbeiceps

French: Tyranneau plombé **Spanish**: Mosquerito Coroniplomizo
German: Graukronen-Kleintyrann

Taxonomy. *Pogonotriccus plumbeiceps* Lawrence, 1869, "Bogotá", Colombia.
Genus as presently constituted may be polyphyletic; objective phylogenetic analysis, using molecular characters as well as anatomical ones, is required in order to define generic limits. Anatomical evidence suggests that *P. fasciatus*, *P. griseocapilla* and *P. griseiceps* may be unrelated to others of genus, some or all of which possibly better placed in resurrected genus *Tyranniscus*. Present species was for long placed in a separate genus, *Oreotriccus*, originally by itself and later with *P. griseocapilla*, but appears not to be close to latter. Monotypic.
Distribution. Locally in Andes from C Colombia (W & E cordilleras) S along E slopes to S Peru (S to Cuzco).



Descriptive notes. 11·5 cm. Plumage is bright olive above, with crown grey contrasting sharply with back; loral spot and narrow supercilium white, dark facial crescent bordered posteriorly by white; wings dusky, wingbars, edges of wing-coverts and broad edges of inner remiges yellow to yellowish-white; tail dusky olive; throat greyish-white, lower face grizzled whitish; breastband and flanks olive, grading to bright yellow on belly; iris dark brown; bill small and rounded, black; legs black. Sexes alike. Juvenile undescribed. Voice. Series of short, harsh notes, having quality of ovenbird (Furnariidae) voice, given at long intervals.
Habitat. Humid montane forest, especially wet, mossy cloudforest, at 1200-2200 m.
Food and Feeding. Poorly known. Insects and small fruits. Forages singly or in pairs, usually with mixed-species flocks. Perch-gleans or makes short hover-gleans in canopy. Sometimes lifts one wing over back.
Breeding. Not documented.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Rare to locally fairly common; probably often overlooked. Occurs in Tambito Nature Reserve (Cauca) and Ucumarí Regional Park, both in Colombia, and in all national parks on E Andean slope of Ecuador. Not uncommon in Machu Picchu Historical Sanctuary (e.g. along railway track between Puente Ruinas and Mandor Valley), in Peru.
Bibliography. Chapman (1917c, 1926), Cory & Hellmayr (1927), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Miller (1963), Meyer de Schauensee (1982), Miller (1963), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robbins & Ridgely (1990), Stotz *et al.* (1996), Traylor (1977), Walker (2001), Weske (1972), Zimmer (1930, 1941c).

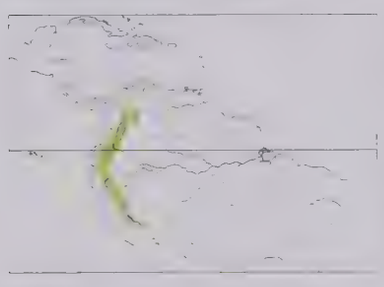
10. Black-capped Tyrannulet

Phyllomyias nigrocapillus

French: Tyranneau à tête noire **Spanish**: Mosquerito Capirotado
German: Schwarzkappen-Kleintyrann

Taxonomy. *T[yrannulus] nigro-capillus* Lafresnaye, 1845, "Bogotá", Colombia.
Genus as presently constituted may be polyphyletic; objective phylogenetic analysis, using molecular characters as well as anatomical ones, is required in order to define generic limits. Anatomical evidence suggests that *P. fasciatus*, *P. griseocapilla* and *P. griseiceps* may be unrelated to others of genus, some or all of which possibly better placed in resurrected genus *Tyranniscus*. Present species was for long placed in latter genus. Three subspecies recognized.
Subspecies and Distribution.
P. n. flavimentum (Chapman, 1912) - Santa Marta Mts, in N Colombia.
P. n. nigrocapillus (Lafresnaye, 1845) - Andes of extreme W Venezuela, Colombia (except Santa Marta), W & E Ecuador and E Peru (S to Junín).
P. n. aureus (J. T. Zimmer, 1941) - Andes of W Venezuela (S Lara S to N Táchira).

Descriptive notes. 11·5 cm. Nominate race has white loral spot and narrow supercilium, dark facial crescent bordered posteriorly by white; crown dark grey to blackish, sharply contrasting with bright olive upperparts; wings dusky, yellow to yellowish-white wingbars and broad edges of inner remiges; tail dusky olive; throat greyish-white, lower face grizzled whitish; breastband and flanks olive, grading to bright yellow on belly; iris dark brown; bill small and rounded, black; legs black. Sexes alike. Juvenile undescribed. Race *flavimentum* has deep yellow lores and supercilium, much deeper yellow underparts lacking whitish chin, richer yellow wingbars; *aureus* has dusky grey-brown crown, more golden overtones throughout. Voice. Emphatic series of clear, high-pitched notes, "tzi-tzi-tzrr" or "peeep, peeeep", often repeated persistently.
Habitat. Humid montane forest, especially dense, mossy cloudforest and open, mossy woodlands and edges of clearings at upper elevations, even in stunted elfin forest near tree-line; also second growth. Mostly 1600-3400 m, rarely down to c. 1000 m; 1500-3000 in Venezuela.
Food and Feeding. Insects, small fruits. Forages alone or in pairs, usually with mixed-species flocks, in middle to upper parts of trees in densest parts of mossy forest. Very active, perches



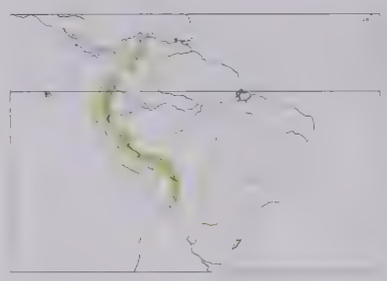
horizontally, tail often slightly cocked, flicks wings and pivots on perch while perch-gleaning in dense leaves and moss; occasionally hover-gleans, especially to pluck small berries.
Breeding. Birds with enlarged gonads in Mar-Nov in N Colombia. No other information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Rare to locally common, but perhaps often overlooked; apparently less numerous in S (Peru). Often most common near tree-line, and in S Ecuador particularly common along upper part of Loja-Zamora road. Can be found in majority of protected areas in its range. Tolerates converted habitat.
Bibliography. Allen (1998), Chapman (1917c, 1926), Cory & Hellmayr (1927), Cracraft (1985), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Miller (1963), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robbins & Ridgely (1990), Salaman (1994), Stotz *et al.* (1996), Strewe & Navarro (2003), Traylor (1977), Weske (1972), Zimmer (1941b).

11. Ashy-headed Tyrannulet

Phyllomyias cinereiceps

French: Tyranneau à tête cendrée **German**: Ohrfleck-Kleintyrann **Spanish**: Mosquerito Cenizo

Taxonomy. *Tyrannulus cinereiceps* P. L. Sclater, 1860, Pallatanga, Chimborazo, Ecuador.
Genus as presently constituted may be polyphyletic; objective phylogenetic analysis, using molecular characters as well as anatomical ones, is required in order to define generic limits. Anatomical evidence suggests that *P. fasciatus*, *P. griseocapilla* and *P. griseiceps* may be unrelated to others of genus, some or all of which possibly better placed in resurrected genus *Tyranniscus*. Present species was for long placed in latter. Monotypic.
Distribution. Andes in extreme SW Venezuela (S Táchira), Colombia (all three cordilleras), W & E Ecuador and E Peru (S to Cuzco).



Descriptive notes. 11 cm; c. 10 g. Has slaty blue-grey crown sharply contrasting with bright olive back; lores and eyering white; face pattern distinctive, grizzled white and black, cheek patch yellowish, large black crescent on rear auriculars bordered posteriorly by yellow; wings dusky, two wingbars and edges of inner remiges broadly yellow; tail dusky olive; throat greyish-white, breast and flanks streaked or flammulated with olive, grading to bright yellow on belly; iris dark red; bill small and rounded, black; legs black. Sexes alike. Juvenile undescribed. Voice. Piercing and far-carrying, a high-pitched note followed by descending trill, "sweeeee, see-ee-ee-ee-eew".
Habitat. Humid upper montane forest, especially cloudforest, forest borders, also adjacent second growth. At 1400-2700 m; in Ecuador mostly 1350-2500 m, locally down to 900 m in S (El Oro).
Food and Feeding. Insects; probably also some small fruits. Forages in middle and upper levels of trees, usually with mixed-species flocks. Sits quietly for short periods, with slightly hunched posture, sometimes lifts one wing over head; flits quickly to new perch or hover-gleans from leaves or moss, sometimes hanging on leaves briefly to perch-glean; sometimes makes quick, short aerial sallies.
Breeding. Fledglings seen in Oct and Nov in Colombia. No other information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Rare to locally fairly common; probably often overlooked. More common in upper Magdalena Valley and Cueva de los Guácharos National Park, both in Colombia, and present in all national parks in humid Andean zones of Ecuador and Peru. Only three records from Venezuela, one in 1988 and two in 1996. Possibly occurs also in Bolivia (Madidi National Park).
Bibliography. Chapman (1917c, 1921, 1926), Cory & Hellmayr (1927), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Miller (1963), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robbins & Ridgely (1990), Salaman (1994), Stotz *et al.* (1996), Traylor (1977), Walker (2001), Walker *et al.* (2003), Weske (1972), Zimmer (1941b).

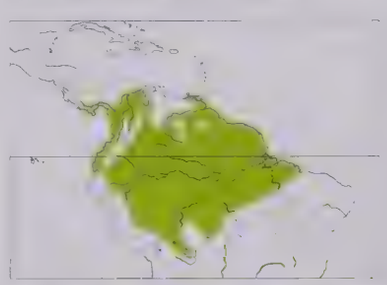
12. Tawny-rumped Tyrannulet

Phyllomyias uropygialis

French: Tyranneau à croupion fauve **Spanish**: Mosquerito Culirrufo
German: Zimtbürzel-Kleintyrann

Taxonomy. *Mecocerculus uropygialis* Lawrence, 1869, Corazón, Pichincha, Ecuador.
Genus as presently constituted may be polyphyletic; objective phylogenetic analysis, using molecular characters as well as anatomical ones, is required in order to define generic limits. Anatomical evidence suggests that *P. fasciatus*, *P. griseocapilla* and *P. griseiceps* may be unrelated to others of genus, some or all of which possibly better placed in resurrected genus *Tyranniscus*. Present species was for long placed in latter. Monotypic.
Distribution. Very local in Andes of W Venezuela (Mérida), Colombia (S to Cundinamarca in E cordillera, in Cauca and Nariño in W), W & E Ecuador, and E slope in Peru (also three records on W slope), Bolivia (S to Tarija) and extreme NW Argentina (N Salta).
Descriptive notes. 11 cm; 8-9 g. A slightly crested, small tyrannulet. Has white lores and supercilium, dark brown crown, grading to brownish-olive on back; rump and uppertail-coverts bright cinnamon; wings dark brown, two bright buffy wingbars, edges of inner remiges broadly yellow, edges of outer remiges bright orange-buff; tail dusky, edged with buff; throat greyish-white, lower face greyish; breast and flanks olive-brown, grading to yellow to yellowish-white on belly; iris dark brown; bill small and rounded, black; legs black. Sexes alike. Juvenile undescribed. Voice. Inconspicuous 2-note "tseep-tseep" or "tzeep, zéé-u", singly or in series, especially early in morning.
Habitat. Upper montane humid forest, especially in thickets, edges of clearings, tree-line shrubbery, brushy washes, stunted elfin forest, and forest edges with *Chusquea* bamboo. At 2350-3000 m in Venezuela, 1500-2600 in Colombia, mostly 2100-3000 in Ecuador, and 1800-3000 m in SE Peru (2750 m in Arequipa, on W slope).
Food and Feeding. Insects; probably some small fruits. Forages actively, usually in pairs or small family groups with mixed-species flocks, in canopy or upper parts of dense shrubs. Perches

upright; feeds in manner of a parulidae warbler, with perch-gleans and short upward hover-gleans.
Breeding. Fledgling observed in Dec in Bolivia. No other information.
Movements. Mainly resident, but possibly some seasonal movements to slightly lower elevations; the three records on W slope of Peruvian Andes may represent wandering individuals.
Status and Conservation. Not globally threatened. Rare to locally fairly common; most common in Bolivia. Regular near Hotel Los Frailes (Mérida), in Venezuela; occurs in several protected areas throughout range, including four national parks in Ecuador and probably all national parks from N Peru (Abiseo, in San Martín) S to Bolivia (Carrasco); in Argentina, recorded only in Baritú National Park (N Salta). Has relatively large range, within which it exhibits tolerance of degraded habitats; unlikely to become threatened in immediate future.
Bibliography. Allen (1998), Chapman (1917c, 1926), Cory & Hellmayr (1927), Davies *et al.* (1994), Di Giacomo (1995), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Miller (1963), Remsen (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robbins & Ridgely (1990), Salaman (1994), Sharpe *et al.* (2001), Stotz *et al.* (1996), Traylor (1977), Walker (2001), Walker *et al.* (2003), Weske (1972), Zimmer (1930, 1941b).



Genus *TYRANNULUS* Vieillot, 1816

13. Yellow-crowned Tyrannulet

Tyrannulus elatus

French: Tyranneau roitelet **German**: Gelbscheitel-Olivtyrann **Spanish**: Mosquerito Coronado

Taxonomy. *S[ylvia] elata* Latham, 1790, Cayenne.
Monotypic genus, in many respects transitional between *Phyllomyias* and *Myiopagis*, but anatomical evidence suggests closer relationship to latter. Birds from Panama named as race *panamensis* and birds from N Bolivia as *benii*; in examination of large series of specimens, however, both considered indistinguishable from other populations. Monotypic.
Distribution. Extreme S Costa Rica, Panama, and forested South American lowlands S to WC Ecuador and, E of Andes, from Colombia, Venezuela, the Guianas and Amazonian Brazil (E to Maranhão) S to E Peru and N Bolivia.

Descriptive notes. 10-11 cm; 6·5-8 g. A stubby-billed tyrannulet that is heard far more often than it is seen. Male has slate-grey to dark brown or blackish crown, long bright yellow to orange-yellow coronal stripe (semi-concealed), greyish supercilium; bright olive-green above, wings dusky, two wingbars and indistinct edges of wing-coverts and flight-feathers white to yellowish-white; tail dusky olive, may appear pale-tipped when plumage fresh; throat and face pale grey, underparts pale to medium yellow, breast suffused with olive; iris brown; bill very short and rounded, all black; legs grey. Female is smaller than male, slightly paler above, paler grey crown, paler coronal stripe. Juvenile resembles adult. Voice. Distinctive, easily heard, brief disyllabic call, first note higher and second slightly slurred downwards, "wher-dear" or "pee-dear" ("three bears"), delivered singly at intervals of up to many minutes, often throughout heat of day when few other birds singing.
Habitat. Humid lowland evergreen forest, especially in second growth, forest edges, lighter woodland, shrubby clearings, also coffee or citrus plantations, gardens and parks; also high in canopy of primary forest (sometimes calling from near tops of emergent trees). Lowlands and foothills, to c. 1200 m.
Food and Feeding. Insects and variety of small fruits; recorded foods include *Capsicum* and, especially, mistletoe (Loranthaceae) berries. Forages mainly solitarily or in pairs, only rarely occurring in mixed-species flocks. Perches upright, tail not cocked; perch-gleans and makes short hover-gleans to snatch food items, mainly in outer edges of canopy.
Breeding. Mar-Aug in Panama and Jan-Sept in Colombia. Nest (Panama) a simple, shallow cup 4 cm in diameter, 1 cm deep, made of fine twigs, plant fibre and hair-like filaments, some hanging below nest, placed 8-20 m up on narrow twig or at origin of multiple sprouts from twig, exterior of cup sometimes decorated with numerous small mistletoe seeds regurgitated by female immediately after returning from foraging bouts; nest territory vigorously defended by male against intruding Palm Tanager (*Thraupis palmarum*). Clutch 1 or 2 eggs; incubation evidently by female only; no information on duration of incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to common. Occurs in many national parks and other protected areas throughout its large range. Tolerates degraded and disturbed habitats, and also occurs in artificial habitats, such as plantations and gardens. May be expanding its range N in Central America as a consequence of deforestation.
Bibliography. Anon. (1998a), Bates & Parker (1998), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Davidar (1987), Friedmann (1948), Gilliard (1941), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Hosner (2004), Naka (2004), Oren & Parker (1997), Peres & Whittaker (1991), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robinson & Terborgh (1997), Schulenberg *et al.* (2001), Sick (1993, 1997), Snethlage (1935), Snyder (1966), Stiles (1985), Stiles & Skutch (1989), Stiles & Smith (1980), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977), Walther (2004), Wetmore (1972), Willis (1980), Zimmer (1941c).

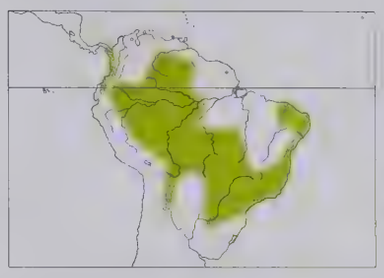
Genus *MYIOPAGIS* Salvin & Godman, 1888

14. Forest Elaenia

Myiopagis gaimardii

French: Élénie de Gaimard **German**: Weißscheitel-Olivtyrann **Spanish**: Fiofío Selvático

Taxonomy. *Muscicapara Gaimardii* d'Orbigny, 1840, Yuracarés, Cochabamba, Bolivia.
Was once placed in its own genus, *Elainopsis*, and moved to the family Cotingidae on basis of its incomplete tarsal envelope. Proposed race *subcinerea* (EC Brazil from lower Amazon Basin E to Maranhão and Goiás) treated as a synonym of nominate; intergrades broadly with latter and with *guianensis*, and most individuals cannot be reliably distinguished from either. Five subspecies currently recognized.
Subspecies and Distribution.
M. g. macilvainii (Lawrence, 1871) - Panama (E of Canal Zone) and Caribbean coast of Colombia (E to base of Santa Marta Mts).
M. g. bogotensis (Berlepsch, 1907) - NE Colombia (from N Santa Marta Mts) E to N Venezuela (W Zulia E to Sucre, S to Barinas, Apure and R Orinoco).
M. g. trinitatis (Hartert & Goodson, 1917) - Trinidad.
M. g. guianensis (Berlepsch, 1907) - E Amazonian Colombia, S & SE Venezuela (S of R Orinoco) and the Guianas S to N Amazonian Brazil and extreme NE Peru (Loreto).
M. g. gaimardii (d'Orbigny, 1840) - E Ecuador, E Peru, S Amazonian Brazil (E to W Pará, also Alagoas, S to W Mato Grosso, W São Paulo and Goiás) and N Bolivia.



Descriptive notes. 12-12·5 cm; 12-13 g. Small, with elongated crown feathers forming slight bushy crest. Nominate race has indistinct whitish loral spot and supercilium, narrow whitish broken eyering; crown dark grey, semi-concealed white coronal patch; upperparts olive, wings dusky, two conspicuous wingbars and outer webs of inner remiges pale to bright yellow; throat whitish, face grizzled white; breast broadly flammulated olive, grading to bright yellow on belly; iris dark brown; bill short, black; legs grey. Sexes alike. Juvenile not described. Races vary mainly in colour of upperparts and concealed crown patch: *guianensis* is very similar to nominate, but slightly darker olive above; *bogotensis* is paler, brighter green above, with suffusion of pale yellow in crown patch; *macilvainii* has bright yellow crown patch; *trinitatis* is significantly larger than others, has more extensive whitish throat, broader grey breast. Voice. Short, upward-inflected, disyllabic "pitchueeet", typically as isolated calls or separated by intervals of 30 seconds or more; often calls throughout day.
Habitat. Tropical lowland evergreen forest, forest borders, gallery forest and, to lesser extent, deciduous forest and secondary woodland; often found in emergent trees, and in association with forest openings such as treefall gaps, small streams and small clearings. Mainly below 1000 m, but recorded to 1500 m.
Food and Feeding. Insects; berries and small fruit also eaten. Forages usually very high in forest canopy; often, but not always, with mixed-species flocks. Perches both upright and somewhat horizontally, often cocks tail slightly; often inactive, changing perches infrequently by flitting short distances. Perch-gleans and hover-gleans in foliage and twigs. Of 75 food captures observed in tall deciduous forest in N Venezuela, 35% involved upward hover-gleaning, 11% downward hover-gleaning, 3% upward strikes, 3% downward strikes, 34% perch-gleaning; small fruit taken in 16% of cases.
Breeding. Nest found in Feb in Panama; breeds Mar-Sept in Colombia and Feb-Sept in Trinidad. Nest (Panama) a cup of grass and moss, decorated with lichens, 3-5 m up in fork of tree branch. Clutch 2 eggs; incubation and fledging periods not known.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common in much of range, but easily overlooked unless voice known; difficult to locate in forest canopy and heard much more often than it is seen. Occurs in many national parks and other protected areas throughout its large range. Much of this species' habitat remains in relatively good condition, and it is not considered likely to become threatened within the immediate future.
Bibliography. Anon. (1998a), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Delgado (1985), Dubs (1992), ffrench (1991), Fitzpatrick (1980c), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Munn (1985), Oren & Parker (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robinson & Terborgh (1997), Schulenberg *et al.* (2001), Sick (1993, 1997), Silveira *et al.* (2003), Stotz *et al.* (1996), Temple (2002), Tostain *et al.* (1992), Traylor (1977), Walther (2004), Wetmore (1972), White (2002), Willis (1980), Zimmer (1941a).

15. Grey Elaenia

Myiopagis caniceps

French: Élénie grise **German**: Grautyrann **Spanish**: Fiofío Gris
Other common names: Bananal Tyrannulet ("*Serpophaga araguayae*")

Taxonomy. *Tyrannula caniceps* Swainson, 1835, Santo Amaro, Reconcavo da Bahia, Brazil.
Apparently closely related to *M. olallai*, but also suggested by some as possibly not belonging in present genus on grounds of sexual plumage dimorphism. Described taxon *Serpophaga araguayae*, based on a single specimen from SW Tocantins (Bananal I), in Brazil, shown to be referable to nominate race of present species. Four subspecies recognized.
Subspecies and Distribution.
M. c. absita (Wetmore, 1963) - E Panama.
M. c. parambae (Hellmayr, 1904) - Chocó region of W Colombia and NW Ecuador.
M. c. cinerea (Pelzeln, 1868) - E Colombia E through NW & S Venezuela (Zulia, Bolívar, Amazonas) to SW Guyana and French Guiana, and S through E Ecuador, E Peru and W Amazonian Brazil (E to R Purus) to N Bolivia.
M. c. caniceps (Swainson, 1835) - NE, S & SE Brazil (Ceará, Alagoas, and from S Mato Grosso and Maranhão S to São Paulo and Rio Grande do Sul), Paraguay, S Bolivia (Tarija) and extreme NW & NE Argentina.

Descriptive notes. 12-12·5 cm; 10-11 g. Sexually dimorphic elaenia, local populations extremely variable. Male nominate race has narrow white crown patch (concealed), indistinct whitish loral spot; forehead to hindneck medium-grey, becoming more olive-grey on upperparts; wings black, two conspicuous wingbars and outer webs of inner remiges white; tail greyish; face grizzled whitish, throat white, breast pale grey, belly greyish-white; iris dark brown; bill short and rounded, blackish; legs grey. Female is bright greenish-olive above, crown and nape medium grey, concealed crown patch pale yellow; wings as male but wingbars and edges of remiges pale to bright yellow; face grizzled greyish-white, throat and breast pale grey, rest of underparts greyish-white, faintly washed pale yellow. Immature male resembles female. Race *cinerea* is similar to nominate, but male more blue-grey, white markings on wings broader, bill larger, female brighter green above, underparts pale greenish-yellow to bright yellow, wing markings yellower and more extensive; *parambae* resembles previous but much smaller, female has coronal patch white; *absita* is paler, with more extensive white on wing, female has paler yellow underparts. Voice. A very fast, high series of notes, trailing off into descending trill; also high-pitched single or double "wheep", an excited "e-e-e-e-pitchew pitchew-peechew", and a buzzy call of 2-3 notes.
Habitat. Tropical lowland evergreen forest and borders of humid forest, both *terra firme* and *várzea*. Mainly in foothills in Panama; from sea-level to 1200 m in other parts of range.
Food and Feeding. Insects, also small fruits. Normally forages high above ground in treetops and outer canopy foliage, often with mixed-species flocks. Posture erect or horizontal; often cocks tail slightly. Perch-gleans and hover-gleans among foliage and twigs.
Breeding. Sept-Jan in S Brazil and Argentina. Nest (Argentina) a neat cup 7·5 cm in diameter, 4 cm high, composed of vegetable fibres, decorated on exterior with lichens, placed 7 m above ground in crotch of large branch. Clutch 2 eggs; incubation and fledging periods not recorded.
Movements. Resident in N; some withdraw from extreme S parts of range during austral winter. Probable migrant recorded in extreme NW Venezuela (Zulia).
Status and Conservation. Not globally threatened. Rare to locally uncommon; often difficult to see, and rather few records in many countries in its range, but easily overlooked unless voice known. Occurs in many national parks and other protected areas throughout its range, e.g. from Darién National Park, in Panama, and Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, S to Caaguazú National Park, in Paraguay, and Iguazú National Park, in Argentina. Large areas of suitable habitat within the species' range remain relatively undisturbed.
Bibliography. Anon. (1998a), Bates & Parker (1998), Belton (1985), Brooks *et al.* (1993), Canevari *et al.* (1991), Chesser (1997), Cohn-Haft *et al.* (1997), Collar & Andrew (1988), Cory & Hellmayr (1927), Darrieu (1987), Delgado (1985), Dubs (1992), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Lowen *et al.* (1996), Meyer de Schauensee (1982), Naka (2004), Pacheco & Laps (2001), de la Peña (1988), Peres & Whittaker (1991), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), da Silva (1990), Stotz *et al.* (1996), Teixeira *et al.* (1988), Traylor (1977), Walther (2004), Wetmore (1972), Zimmer (1930, 1941a).

16. Foothill Elaenia

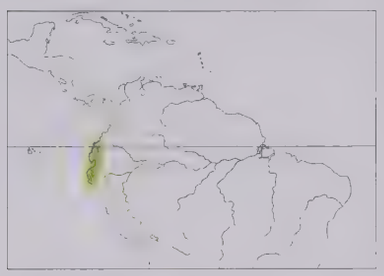
Myiopagis olallai

French: Élénie d'avant-monts **German**: Vorgebirgs-Olivtyrann **Spanish**: Fiofío Submontano

Taxonomy. *Myiopagis olallai* Coopmans and Krabbe, 2000, River Bambuscaro, Zamora-Chinchipe, Ecuador.
Probably most closely related to *M. caniceps*. Monotypic.
Distribution. Locally in E Andes of N & S Ecuador and in SC Peru (Cordillera Vilcabamba, in Ayacucho).

Descriptive notes. 12-12·5 cm; 11-14 g. Has dark pearly grey crown with large white coronal patch (semi-concealed), whitish-mottled lores, eyering and subocular region; upperparts olive; wings dusky, washed olive on coverts, three conspicuous wingbars and outer webs of inner remiges bright yellow; tail grey-brown; throat whitish, underparts bright yellow, breast broadly flammulated olive; iris dark brown; bill short, black, base of lower mandible brownish-grey; legs black. Sexes alike. Juvenile undescribed. Voice. Long, harsh trill distinctly rising in pitch, lasting c. 2 seconds, preceded by variable number of introductory notes.
Habitat. In and around edge of very humid to wet submontane primary forest, at elevations of 890-1500 m.
Food and Feeding. Diet unknown; probably insects and some berries. All observations relate to pairs accompanying mixed-species flocks at canopy and middle levels of forest. While foraging, perches horizontally, often with tail cocked; generally very active, making short upward or outward sallies, briefly hover-gleaning from tops and undersides of foliage, moss, twigs and branches. Calls and sings frequently while perched vertically at tip of a branch 2-15 m from ground.
Breeding. No information.
Movements. No information.

On following pages: 17. Pacific Elaenia (*Myiopagis subplacens*); 18. Yellow-crowned Elaenia (*Myiopagis flavivertex*); 19. Jamaican Elaenia (*Myiopagis cotta*); 20. Greenish Elaenia (*Myiopagis viridicata*); 21. Caribbean Elaenia (*Elaenia martinica*); 22. Yellow-bellied Elaenia (*Elaenia flavogaster*); 23. Large Elaenia (*Elaenia spectabilis*); 24. Noronha Elaenia (*Elaenia ridleyana*); 25. White-crested Elaenia (*Elaenia albiceps*); 26. Small-billed Elaenia (*Elaenia parvirostris*); 27. Olivaceous Elaenia (*Elaenia mesoleuca*).



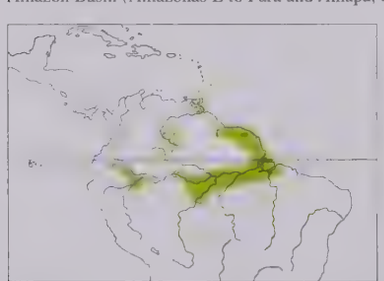
Status and Conservation. Not globally threatened. Recently discovered species. In Ecuador, recorded in Napo and Zamora-Chinchipe, and, more recently, in foothills of W Andean slopes in Sucumbíos (Serranías Cofán), where it is uncommon; in Peru, recorded at three localities in foothills of E slopes, in Ayacucho. Occurs in Sumaco-Galeras and Podocarpus National Parks, in Ecuador, but at lower elevations where threat of deforestation by human settlers most imminent. Forests within this species' elevational range are disappearing at an alarming rate along much of E Andean slopes. On the other hand, it is found also in superwet forest, where human pressure hitherto more moderate. Fieldwork needed in order to determine the species' true status and its ecological requirements.
Bibliography. Anon. (2000c), Coopmans & Krabbe (2000), Green (2002a), Van Loon (2001).

17. Pacific Elaenia

Myiopagis subplacens

French: Élénie striée **German**: Weißbrauen-Olivtyrann **Spanish**: Fiofío del Pacífico

Taxonomy. *Elainea* [sic] *subplacens* P. L. Sclater, 1862, Pallatanga, Chimborazo, Ecuador.
Possibly close to *M. viridicata*. Monotypic.
Distribution. W Ecuador (S from Esmeraldas, including Puná I) and NW Peru (Tumbes, W Piura).



Descriptive notes. 13·5 cm. Has grey-brown crown, large bright yellow coronal patch (semi-concealed); indistinct whitish lores, broad white supercilium extending downwards behind blackish auricular region, narrow broken whitish eyering; upperparts brownish-olive; wings dusky, two yellowish wingbars (indistinct to nearly absent), outer webs of inner remiges pale yellow; tail greyish-olive; face grizzled whitish, throat and breast flammulated pale greyish-white, rest of underparts pale yellow; iris dark brown; bill short, blackish, base of lower mandible paler; legs grey. Sexes alike. Juvenile undescribed. Voice. Sharply delivered "cheer-woorr-it!"; dawn song "chrrr, chrrr, che-wik" repeated over and over.
Habitat. Lower growth and borders of deciduous forest, semi-humid gallery forest and woodland, and secondary scrub; lowlands and foothills, to 1750m. Avoids humid forest.
Food and Feeding. Little known. Usually solitary; seldom joins mixed-species flocks. Quiet and inconspicuous; perches upright.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA. Uncommon to fairly common. Numbers have declined as a result of widespread deforestation, but still fairly common in several forested regions, such as Chongón Hills (W of Guayaquil) and Machalilla National Park, in Ecuador, where also recorded in Cerro Blanco Forest Reserve, Loma Alta Ecological Reserve and Río Palenque Scientific Station. Occurs in Northwest Peru Biosphere Reserve. Forest habitats within Tumbesian region are being rapidly destroyed, degraded and fragmented by clearance, and by understorey disturbance resulting from timber extraction and livestock grazing. In W Ecuador below 900 m, 57% of forest was lost per decade from 1958 to 1988, and virtually all lowland forest outside protected areas likely soon to be destroyed; at higher elevations, deforestation has been slower and a greater proportion of forest survives, but overall still less than 5% of original forest cover remains, mostly on inaccessible slopes. Even nominally protected areas are subject to logging, grazing, illegal settling and habitat clearance.
Bibliography. Best & Clarke (1991), Cory & Hellmayr (1927), Lanyon (1988b), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1977), Williams & Tobias (1994), Zimmer (1941a).

18. Yellow-crowned Elaenia

Myiopagis flavivertex

French: Élénie à couronne d'or **Spanish**: Fiofío Coroniamarillo
German: Goldscheitel-Olivtyrann

Taxonomy. *Elainea* [sic] *flavivertex* P. L. Sclater, 1887, near Cachiboya, upper Ucayali, Peru.
Probably most closely related to *M. viridicata*. Monotypic.
Distribution. Very locally in NE & S Venezuela (NE Monagas S to Delta Amacuro, Amazonas), the Guianas, NE Ecuador (Sucumbíos, N Napo), NE Peru (E Loreto) and C Brazil along middle Amazon Basin (Amazonas E to Pará and Amapá, S to N Rondônia).

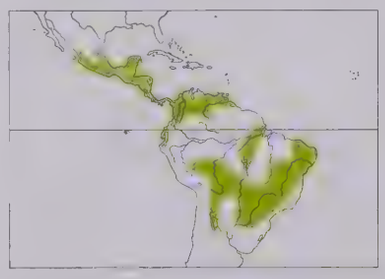
Descriptive notes. 12·5-13 cm; 12 g. Has dark brownish-olive crown, large bright yellow coronal patch (semi-concealed); indistinct whitish loral spot and supercilium; upperparts olive; wings dusky olive, two conspicuous wingbars and outer webs of inner remiges bright yellow; face and throat whitish, breast olive-washed yellow, rest of underparts bright yellow; iris dark brown; bill short, blackish, base of lower mandible pinkish; legs grey. Sexes alike. Juvenile undescribed. Voice. Distinctive, loud "jéw, jee-jee-jew" or "wéechéché-e-e-e", sometimes in faster, longer series of notes, given singly and intermittently.
Habitat. Lower and middle growth of *várzea* and flooded, swampy forest, sometimes in flooded forest in sandy-soil areas; at elevations of up to 300 m (tropical zones).
Food and Feeding. Insects recorded. Found singly or as loosely associated pair; rarely with mixed-species flocks. Perches upright, remains relatively still for long periods; occasionally sallies short distances to glean insects among foliage.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common; not well known, but overlooked unless voice known. Generally very localized in occurrence; e.g. in Ecuador, found along R Aguarico, R Lagarto, R Napo (including La Selva and Yuturi Lodges) and R Pacuyacu, and fairly common at Cuyabeno. Occurs in several protected areas, including Anavilhanas Ecological Station, in Brazil.
Bibliography. Bangs & Penard (1918), Cory & Hellmayr (1927), Gyldenstolpe (1950), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Lanyon (1988b), Meyer de Schauensee (1982), Novaes (1978a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1993, 1997), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977), Zimmer (1941a).

19. Jamaican Elaenia

Myiopagis cotta

French: Élénie de la Jamaïque **German**: Weißkehl-Olivtyrann **Spanish**: Fiofío Jamaicano
Other common names: Jamaican Yellow-crowned Elaenia, Yellow Elaenia

Taxonomy. *Elania cotta* Gosse, 1849, Jamaica.
Closely related to, and considered by some to be conspecific with, *M. viridicata*. Monotypic.
Distribution. Jamaica.



Descriptive notes. 12-12·5 cm; 12-13 g. Plumage is greenish-olive above, crown slightly darker and with feathers slightly elongated, concealing bright orange-yellow coronal patch; whitish lores and supercilium bordered below by darkish line through eye; wings dusky olive, outer webs of inner remiges edged pale yellow; tail dusky olive; throat whitish, face grizzled white; breast pale yellow, rest of underparts bright yellow; iris dark brown; bill short, black; legs blackish. Sexes alike. Juvenile lacks coronal patch, has pale grey underparts, yellower on belly. Voice. Rapid, high-pitched "ti-si-si-sip".
Habitat. Open woodland, forest edge, second-growth forest, scrubland, shade coffee plantations, and dry forest; from sea-level to mountains, to 2000 m. Most frequent in wet forest at middle elevations.
Food and Feeding. Insects; rarely, fruits. Forages from understorey to canopy, but typically 4-8 m above ground. Sallies from perch, gleans items from vegetation while in flight.
Breeding. Mar-Jun. Nest a well-formed cup of plant materials, hidden in foliage. Clutch 3 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Jamaica EBA. Uncommon but widespread. In Jamaica, 75% of original forest cover has already been cleared, and remaining forest is largely second growth; undisturbed forest survives only on high, steep mountain slopes, some of which are protected in Blue Mountain and John Crow National Park, but hunting and habitat destruction continue because of lack of funds for protection and management. Resurgence in coffee cultivation since 1980 has led to clearance of much second growth, and other problems for remaining forests include hurricane damage, widespread pesticide use, establishment of pine (*Pinus*) plantations, timber removal, deliberate fires, and continuing conversion for small-scale farming and urbanization.
Bibliography. Anon. (1998a), Bond (1985), Cory & Hellmayr (1927), Faaborg (1985), Lanyon (1988b), Pregill *et al.* (1991), Raffaele *et al.* (1998, 2003), Ridgway (1907), Stotz *et al.* (1996), Traylor (1977).

20. Greenish Elaenia

Myiopagis viridicata

French: Élénie verdâtre **German**: Grüntyrann **Spanish**: Fiofío Verdoso

Taxonomy. *Sylvia viridicata* Vieillot, 1817, Paraguay.
Closely related to *M. cotta*, which is considered conspecific by some. Possibly also close to *M. subplacens*. Races *pallens*, *zuliae* and *restricta* differ minimally from *accola*, perhaps better merged with last. Ten subspecies tentatively recognized.
Subspecies and Distribution.
M. v. jaliscensis Nelson, 1900 - W Mexico (Nayarit and Zacatecas S to Guerrero).
M. v. minima Nelson, 1898 - Tres Marias Is, off Nayarit (Mexico).
M. v. placens (P. L. Sclater, 1859) - E Mexico (Veracruz S to Yucatán Peninsula, and Cozumel I), Caribbean slope of Guatemala and E Honduras.
M. v. pacifica (Brodkorb, 1943) - Pacific slope from S Mexico (Chiapas) S to W Honduras.
M. v. accola Bangs, 1902 - Nicaragua S to N & NW Colombia and NW Venezuela (Táchira).
M. v. pallens Bangs, 1902 - N Colombia (Santa Marta region, Cundinamarca, Huila).
M. v. zuliae J. T. Zimmer & Phelps, Sr, 1955 - foothills of Sierra de Perijá in extreme N Venezuela.
M. v. restricta Todd, 1952 - coastal mountains and lowlands of Venezuela (E of Andes, N of Amazon Basin), also Guyana.
M. v. implacens (P. L. Sclater, 1862) - SW Colombia (Nariño), W Ecuador (S to Loja) and extreme NW Peru.
M. v. viridicata (Vieillot, 1817) - SE Peru, N Bolivia, SC, E & SE Brazil, Paraguay, and NW & NE Argentina (S to Tucumán, Formosa and Corrientes).

Descriptive notes. 13·5 cm; 12-14 g. Male nominate race is greenish-olive above, crown faintly tinged greyish, feathers slightly elongated, yellow to yellow-orange coronal patch (semi-concealed); indistinct whitish supercilium, narrow broken white eyering, darker loral stripe; wings dusky, wing-coverts and outer webs of inner remiges indistinctly edged pale yellowish-white (no obvious wingbars); tail dusky olive; throat pale grey to whitish, face grizzled white; breast greyish, broadly flammulated olive, rest of underparts pale yellow; iris dark brown to reddish-brown; bill short, blackish, lower mandible flesh-coloured at base; legs dark grey. Female is slightly smaller, has paler crown patch. Juvenile has brownish head and upperparts, lacks crown patch, has wing-coverts tipped brownish, throat tinged buffy, underparts paler yellow. Races vary in body size, bill size, overall richness of colour, and relative

colour of upperparts and crown: *jaliscensis* is palest overall, small-billed; *minima* is unusually small; *placens* is brighter green above; *pacifica* is duller olive above, paler below; *accola* has larger bill, slightly greener upperparts; *pallens* is extremely similar to previous, but on average slightly paler above and below; *restricta* is somewhat larger than last; *zuliae* has deeper, more brilliant yellow abdomen, brighter green (less brownish) back and rump; *implacens* is significantly smaller than last three, has side of crown dull blackish, back richer green, edges of wing-coverts and remiges brighter yellowish. Voice. High-pitched, rather weakly slurred, buzzy or reedy, descending disyllabic call, "sleeeryip" or "cheee-e" or "squeewzit", or "peeeur"; also thin "tzeeeu" or "skzeet". Highly variable dawn song, most often a thin "chew-er-ee-u" or "peer-weedyum", repeated endlessly every 2-3 seconds, sometimes becoming more excited and varied; also more lisping "see-ee, seer, seer", repeated.

Habitat. Humid tropical evergreen forest regions, but prefers lighter growth, especially near streams and clearings, including deciduous and semi-deciduous woodlands, older second growth forest, citrus and coffee plantations, gallery forest, and tall scrub. Mostly sea-level to 1100 m, occasionally to 1500 m; to 2500 m in Middle America.

Food and Feeding. Various insects; wide variety of small berries, fruits and arillate seeds also regularly eaten. Forages singly, or as widely separated pair-members; only rarely with mixed-species flocks. At all levels from lower mid-storey to canopy of forest and tall scrub, most often high in crowns of trees. Perches upright, usually rather quietly, and for long periods (30-45 seconds), inconspicuous; makes short aerial sallies and hover-gleans.

Breeding. Apr-Jun in Middle America, Oct-Mar in Brazil, three nests Dec-Jan in Argentina. Nest built by female, guarded by male, a very thin, shallow cup made of vine tendrils, rootlets and spider silk, attached by rim in fork or saddled in leaf axil 4-10 m above ground in tree; so thin that eggs visible from below through nest bottom. Clutch 2 eggs; incubation and fledging periods not documented.

Movements. Mainly resident; some winter stragglers occur on offshore and Caribbean islands, and recorded once in S USA. Populations in extreme S, in SE Brazil (Rio Grande do Sul), apparently absent in non-breeding season, suggesting that at least some N movement occurs.

Status and Conservation. Not globally threatened. Uncommon to common; often overlooked. Occurs in many national parks and other protected areas throughout its range, from Middle America S to Argentina. Does not require primary forest; has adapted to secondary habitats and tolerates moderate levels of disturbance. Much suitable habitat remains, and this species is not considered likely to become threatened in near future.

Bibliography. Anon. (1998a), Belton (1985), Binford (1989), Brooks *et al.* (1993), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Cracraft (1985), Darrieu (1987), Di Giacomo (2004), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Land (1970), Lee Jones (2004), Lowen *et al.* (1996), Mees (2000), Monroe (1968), Morgan & Feltner (1985), Narosky & Salvador (1998), de la Peña (1988), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robinson & Terborgh (1997), do Rosário (1996), Rowley (1962), Sick (1993, 1997), Skutch (1981), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Traylor (1977), Wetmore (1972), Willis (1988), Wright *et al.* (1985), Zimmer (1941a).

Genus *ELAENIA* Sundevall, 1836

21. Caribbean Elaenia

Elaenia martinica

French: Élénie siffleuse **German**: Weißkinn-Olivtyrann **Spanish**: Fiofío Caribeño
Other common names: Chinchorro Elaenia (*chinchorrensis*)

Taxonomy. [*Muscicapa*] *martinica* Linnaeus, 1766, Martinique.

Probably a Caribbean sister-taxon of *E. chiriquensis*. Race *chinchorrensis* considered possibly a separate species by some authors. Seven subspecies recognized.

Subspecies and Distribution.

E. m. remota Berlepsch, 1907 - islands off Quintana Roo (Cozumel, Holbox, Meco, Mujeres, Culebra Cay), in SE Mexico.

E. m. chinchorrensis Griscom, 1926 - Chinchorro Bank (Great Cay), off Quintana Roo (SE Mexico), and outermost cays off Belize (Half-moon Cay, Middle Cay, Glover's Reef).

E. m. cinerescens Ridgway, 1884 - islands of Old Providence, St Andrew's and Santa Catalina, E of Honduras.

E. m. caymanensis Berlepsch, 1907 - Cayman Is.

E. m. riisii P. L. Sclater, 1860 - Puerto Rico and offshore islands (Culebra, Culebrita, Vieques, Southwest Cay), Virgin Is, Anguilla, St Martin, St Bartholomew, Antigua and Barbuda, and Netherlands Antilles (Aruba, Curaçao, Bonaire).

E. m. martinica (Linnaeus, 1766) - Lesser Antilles from Saba and St Eustatius S to Grenada (probably excluding Grenadines).

E. m. barbadensis Cory, 1888 - Barbados.

Descriptive notes. c. 16-18 cm. Relatively large elaenia with rather prominent crest. Forehead to hindneck and upperparts are dull olive to brownish-olive, with pure white coronal patch; very thin whitish eyering, cheeks slightly mottled grey-brown; wings dusky, two whitish wingbars, yellowish to whitish edgings of remiges; tail dusky; throat sooty grey, fading to whitish or dull yellowish on belly; undertail-coverts yellowish to whitish; iris dark brown; bill black, base of lower mandible flesh-coloured; legs black. Differs from very similar *E. chiriquensis* in slightly larger size, more prominent crest, more white in crown. Sexes alike. Juvenile resembles adult. Race *remota* is smaller than nominate, with browner rump, greyer throat and chest; *chinchorrensis* is similar in size and structure, but upperparts less greenish-olive, more dark brownish (darkest on nape), no yellow tinge on belly; *cinerescens* is larger than nominate, with stronger yellow wash on belly; *riisii* is smaller and paler; *caymanensis* is similar to previous in paler coloration, but larger; *barbadensis* is also larger than nominate in all proportions, also somewhat darker below. Voice. Call a sharply whistled, sometimes slightly burry "wee-weew" or "wee-wee-weew" or "pe-weeer"; dawn song a loud clear "pee-wee-reereeree" or "peeweetprrr".

Habitat. Almost ubiquitous on most islands. Most common in canopy and borders of humid lowland evergreen forest, in deciduous woodland, scrub, tall cultivated woodland and gardens, and open land with scattered trees and shrubs, and in mangroves. Primarily in lowlands, occasionally to higher elevations on volcanic islands. Occurs in mountains in S Lesser Antilles, where range overlaps with that of *E. flavogaster*.

Food and Feeding. Both insects and fruit. Forages alone or in pairs. Often perches at edge of vegetation on semi-exposed perches, but not especially conspicuous or noisy; often sits silently in foliage for long periods of time. Sallies into air or against vegetation to hover-glean prey.

Breeding. Jan-Sept. Nest a flimsy shallow cup of twigs, up to 9 m above ground in shrub or tree. Clutch 2-3 eggs; incubation and fledging periods not documented.

Movements. Mainly sedentary; no seasonal movements. Vagrants on mainland and large fluctuations in numbers on Puerto Rico suggest that individuals probably disperse regularly to nearby islands.

Status and Conservation. Not globally threatened. Generally common and widespread; apparently less common in Netherlands Antilles, where rare on Aruba; rare on Old Providence and St Andrew's (race *cinerescens*). Fairly recently established on main island of Puerto Rico, where subsequent rapid increase in numbers was followed by decline; occurs in Guanica International Biosphere Reserve.

Bibliography. Adolph & Roughgarden (1983), Allen (1961), Anon. (1998a), Bangs (1916), Biaggi (1983), Blake, E.R. (1953), Bond (1985), Bradley (2000), Cory & Hellmayr (1927), Faaborg (1985), Griscom (1950), Howell & Webb (1995a), Howell *et al.* (1992), Iliff (1998), Johnston (1975), Keith (1997), Lanyon (1988b), Marini & Cavalcanti (1998), Meyer de Schauensee (1982), Noble (1916), Paynter (1955), Raffaele (1989), Raffaele *et al.* (1998, 2003), Ricklefs & Cox (1977), Ridgely & Tudor (1994), Ridgway (1907), Schuchmann (1981), Steadman *et al.* (1997), Stotz *et al.* (1996), Traylor (1977), Voous (1955, 1965, 1983).

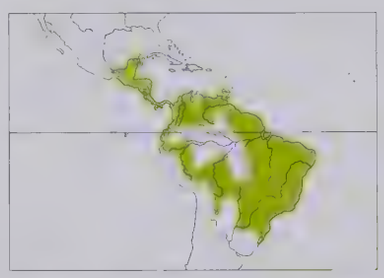
22. Yellow-bellied Elaenia

Elaenia flavogaster

French: Élénie à ventre jaune **German**: Gelbbauch-Olivtyrann **Spanish**: Fiofío Ventriamarillo

Taxonomy. *P[ipra] flavogaster* Thunberg, 1822, presumably Rio de Janeiro, Brazil.

May be closely related to *E. spectabilis*; formerly treated as conspecific, but ranges overlap widely in Brazil, and they have different voices. Birds in SW Colombia appear intermediate between nominate race and *semipagana*. Four subspecies recognized.



Subspecies and Distribution.

E. f. subpagana P. L. Sclater, 1860 - SE Mexico E from S Veracruz and Chiapas (including Mujeres I, off N Quintana Roo) S to Costa Rica, also SW Panama (Coiba I).

E. f. pallididorsalis Aldrich, 1937 - Panama and adjacent islands (except Coiba I).

E. f. flavogaster (Thunberg, 1822) - Colombia, Venezuela (including Margarita I and Patos I), Trinidad, Tobago, S Lesser Antilles (the Grenadines, Grenada), the Guianan Shield, Brazil (S, except in W & C Amazonas, to Rio Grande do Sul), SE Peru, Bolivia, Paraguay and NE Argentina.

E. f. semipagana P. L. Sclater, 1861 - extreme SW Colombia, W & S Ecuador (including Puná I) and interior NW Peru.

Descriptive notes. 16-17 cm; 21-29 g. Medium-sized, small-headed elaenia with conspicuous bushy crest, often parted in middle to reveal white coronal patch. Nominate race is brownish-olive above, face slightly paler than upperparts, faint whitish eyering; wings and tail slightly duskier than back, two white wingbars, yellowish-white edgings on remiges; throat pale grey, breast olive-grey, belly yellow to pale yellow or even whitish; iris dark brown; bill black, pale base of lower mandible; legs black. Distinguished from *E. chiriquensis* by larger size, more conspicuous crest; from *E. spectabilis* by slightly smaller size, much more distinct crest, presence of white crown patch, only two wingbars. Sexes alike. Immature is browner above, buff wingbars, no coronal patch. Race *subpagana* is browner and more olive above, yellower below; *pallididorsalis* is greyer overall, faintly greener on upperparts; *semipagana* is paler overall, greyer front and side of head, much-reduced white coronal patch, whiter throat, paler belly, also shorter bill. Voice. Calls include hoarse "breeer", rising and then falling, and repeated "wreek-kreeup" with hoarse or burry quality; dawn song "trr-dyeéuw, trr-trreeenh-weeeuw" or "we-do, we-do".

Habitat. Variety of humid and arid, wooded habitats, including lighter woodland, second growth and edge, scrub, savanna, as well as brushy river margins, weedy clearings with scattered trees, also trees in towns, gardens; absent from heavily forested areas. Mostly below 1500 m; recorded to 2500 m in Andes.

Food and Feeding. Insects and berries taken. Usually found singly or in pairs; larger numbers may gather at fruiting trees. Animated and conspicuous, typically perching openly and calling frequently, often seeming agitated and excited; crest frequently raised while calling. Forages with aerial sallies, perch-gleans, and hover-gleans.

Breeding. Feb-Sept; May-Sept in Colombia (although birds in breeding condition in Feb), mainly Apr-Jun in Lesser Antilles; mainly Apr-Jun in Trinidad and Tobago, but recorded also in Nov-Dec; nest-building observed in Mar in Venezuela; sometimes two broods. Nest a neat grass or moss cup, lined with feathers and decorated with lichens and bark, placed in fork of small branch. Clutch 2 eggs, rarely 1 or 3; incubation by female, period 16 days; chicks brooded by female, fed by both parents, fledging period 15-17 days.

Movements. Mainly resident; in Mexico, those in Veracruz and Oaxaca largely withdraw to S of Isthmus of Tehuantepec in winter months.

Status and Conservation. Not globally threatened. Fairly common to common throughout most of range; rather uncommon locally, e.g. in parts of Ecuador. Range possibly extends farther S; sight record from N Chile (near Arica). Occurs in numerous national parks and other protected areas. Preference for more open woodland and widespread tolerance of converted habitats, combined with large range, suggest that this species is reasonably secure. Probably of some importance as a seed-disperser; has been shown to disperse seeds widely in second-growth areas.

Bibliography. Anon. 23. Large Elaenia

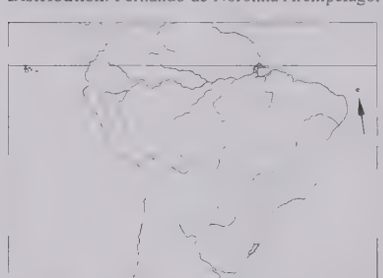
Elaenia spectabilis

French: Élénie remarquable **German**: Graubrust-Olivtyrann **Spanish**: Fiofío Grande

Taxonomy. *Elainea* [sic] *spectabilis* Pelzeln, 1868, Goiás, Brazil.
May be closely related to *E. flavogaster*; formerly treated as conspecific, but ranges overlap widely in Brazil, and they have different voices. Sometimes considered conspecific with *E. ridleyana*, but significant differences in vocalizations. Monotypic.
Distribution. Breeds E of Andes in C, S & E Brazil, E Bolivia, N Argentina and N Uruguay; occurs also, probably only as non-breeding visitor, in Amazon Basin of SE Colombia, E Peru, N Bolivia and W Brazil.



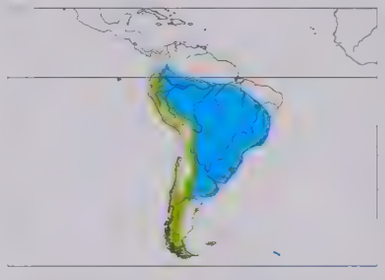
Descriptive notes. 18 cm; 28-30 g. Large elaenia with slight crested appearance. Has head mostly olive-brown, little or no white coronal patch; upperparts uniform dark greyish-olive, wings and tail dusky, two well-marked white wingbars on greater and median wing-coverts, usually also whitish bar on lesser coverts; throat greyish, grading to dark olive-grey on breast, contrasting sharply with yellow belly and undertail-coverts; iris dark brown to grey-brown; bill black, pale flesh-coloured base of lower mandible; legs black. Distinguished from very similar *E. flavogaster* by slightly larger size, less crested appearance, little or no white showing at base of crest, usually a third wingbar (on lesser coverts), and throat more pure grey. Sexes alike. Juvenile resembles adult. Voice. Call a soft "cleeur" or "wheeo", also "wheer" or "cheer", delivered 3-10 seconds apart; dawn song a shrill, repetitious "twee-wee-tweet".
Habitat. Mainly edges of forested habitats in lowlands. Forest borders, shrubby clearings, early-successional riparian zones, second growth, and thickets; mainly in riparian growth and fruiting trees in N during austral winter. Sometimes observed in trees around buildings. Generally in heavier forest than that preferred by *E. flavogaster*.
Food and Feeding. Insects and fruit. Usually forages solitarily, high in canopy. Perches with upright posture; much less excitable and less conspicuous than *E. flavogaster*. Usually perches on exposed twigs at edge of foliage or in treetops, and perch-gleans and hover-gleans.
Breeding. Oct-Mar. Nest a small, neat cup 8 cm in diameter, 4 cm in height, lined with plant fibres and feathers, exterior coated with lichens and mosses, placed 4-6 m above ground in fork of small branch. Clutch 2 eggs; incubation 14-15 days; young fledge in 17-19 days.
Movements. Post-breeding migration N into Amazon Basin; recorded in Colombia from early Jun to late Aug.
Status and Conservation. Not globally threatened. Locally fairly common. Occurs in several protected areas, including e.g. Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Madidi and Noel Kempff Mercado National Parks and Beni Biosphere Reserve, in Bolivia, San Rafael National Park, in Paraguay, Cerro Corá National Park, in Uruguay, and San Juan de Poriahú Private Reserve (in Iberá Provincial Reserve), in Argentina.
Bibliography. Babarskas *et al.* (2003), Bates & Parker (1998), Canevari *et al.* (1991), Chesser (1997), Claramunt & González (1999), Cory & Hellmayr (1927), Di Giacomo (2004), Dubs (1992), Hilty & Brown (1986), Joseph (1996), Klimaitis & Moschione (1987), Krügel *et al.* (2000), Lanyon (1988b), Marini & Cavalcanti (1998), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nicéforo & Olivares (1976), Pearson (1980), de la Peña (1987, 1988, 1995, 1999), Ridgely & Tudor (1994), Robinson (1997), Schulenberg *et al.* (2001), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Wetmore (1972), Zimmer (1941a).

24. Noronha Elaenia

Elaenia ridleyana

French: Élénie de Noronha **German**: Noronha-Olivtyrann **Spanish**: Fiofío de Noronha

Taxonomy. *Elainea* [sic] *ridleyana* Sharpe, 1888, Fernando de Noronha, off Pernambuco, Brazil.
Has been treated as a race of *E. spectabilis* or of *E. chiriquensis*, but differs significantly from both in vocalizations. Monotypic.
Distribution. Fernando de Noronha Archipelago, off coast of NE Brazil (Pernambuco).



Descriptive notes. 17 cm. Large elaenia with slight crested appearance. Head is mostly olive-brown, little or no white coronal patch; upperparts uniform dark greyish-olive, wings and tail dusky, three white wingbars; throat greyish, grading to dark olive-grey on breast, contrasting sharply with yellow belly and undertail-coverts; iris dark brown; bill black, pale flesh-coloured base of lower mandible; legs black. Distinguished from very similar *E. spectabilis* and *E. chiriquensis* by relatively longer bill and shorter tail, from latter also by much larger size. Sexes alike. Juvenile undescribed. Voice. Calls vary, but gives repeated "thiu-thiu-thiu" and "uuu uuu uuu".
Habitat. Dry woodland, open forest, scrub, and thickets around houses.
Food and Feeding. Insects; also small fruits, especially of *Ficus noronhae*. Little known. Perches upright; behaviour apparently similar to that of congeners.
Breeding. Jun-Aug. Nest a neat cup 8 cm across, made of tendrils of Cucurbitaceae and a few fine twigs, lined thickly with woolly down of seeds of *Gonolobus micranthus*, often placed in bare branches of *Burra* or *Erythrina* tree or cashewnut (*Anacardium*) tree. Clutch uncertain, probably 1-2 eggs (1 egg in described nest); incubation and fledging periods not documented.
Movements. Resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in Fernando de Noronha EBA. Uncommon. Present on the main island and on Rata (the largest associated islet), giving global range of only 18 km². Total population c. 100-1000 invididuals, and estimated 480 in the most comprehensive survey; the least common of the archipelago's three resident landbird species. When first discovered by Europeans, in 1503, the archipelago was covered in forest; since then, all large trees have been cut, and all remaining vegetation is secondary. Proposals for tourist development, if carried out, would cause yet greater damage. The species may also suffer from introduced mammals such as rats (*Rattus*) and cats, as well as from activities of children, who target birds with slingshots. Nevertheless, its future should be secure so long as sufficient forest cover survives. Although Fernando de Noronha is a Marine National Park, the effective protection conferred by this designation is not known.
Bibliography. Antas *et al.* (1990), Cory & Hellmayr (1927), Forrester (1993), Marini & Cavalcanti (1998), Olson (1981), Oren (1982), Ridgely & Tudor (1994), Sick (1985, 1993, 1997), Soto *et al.* (2000), Stattersfield & Capper (2000), Stotz *et al.* (1996).

25. White-crested Elaenia

Elaenia albiceps

French: Élénie à cimier blanc **German**: Weißbauch-Olivtyrann **Spanish**: Fiofío Crestiblanco
Other common names: Peruvian Elaenia (*modesta*); Chilean Elaenia (*chilensis*)

Taxonomy. *M[uscipeta] albiceps* d'Orbigny and Lafresnaye, 1837, Yungas, Bolivia.
Closely related to *E. parvirostris*, and vocally very similar; has been suggested that the two are conspecific, but they apparently do not hybridize across broad area of range overlap in Argentina. Race *chilensis* has been treated as a separate species, although no significant vocal differences from others; this race hybridizes locally with *E. parvirostris* where ranges overlap in S Bolivia (but not in NW Argentina). In addition, race *modesta* sometimes treated as a separate species. Race *griseigularis* possibly hybridizes with *E. pallatangae* in Ecuador. Six subspecies currently recognized.
Subspecies and Distribution.
E. a. griseigularis P. L. Sclater, 1859 - SW Colombia S to NW Peru (S to W Cajamarca).
E. a. diversa J. T. Zimmer, 1941 - Andes of NC Peru (Cajamarca S to Huánuco).
E. a. urubambae J. T. Zimmer, 1941 - SE Peru (near Cuzco).
E. a. albiceps (d'Orbigny & Lafresnaye, 1837) - SE Peru (S from Puno) S to NW Bolivia.
E. a. modesta Tschudi, 1844 - W Peru S to NW Chile.
E. a. chilensis Hellmayr, 1927 - breeds in Andes from S Bolivia (Chuquisaca) S to Argentina (S to Catamarca and W Córdoba), thence S in lowlands to Tierra del Fuego; migrates N as far as Peru (possibly Colombia) and NE Brazil (Pará and Bahia).

Descriptive notes. 14·5-15 cm; 15-16 g. Small elaenia, only slightly crested, but white coronal stripe often visible. Nominate race has top of head and upperparts uniform dingy olive-grey, white to creamy coronal patch; face slightly paler than upperparts, distinct but narrow eyering and pale lores; wings and tail duskier, two yellowish-white wingbars, whitish edgings on remiges; throat greyish, breast greyish-brown, belly pale whitish; iris dark brown; bill black, pale greyish base of lower mandible; legs black. Distinguishable from extremely similar *E. parvirostris* by lack of wingbar on lesser coverts, but in the field often proves inseparable from that species, *E. pallatangae* and *E. mesoleuca*. Sexes alike. Juvenile has wingbars yellower, less distinct, than adult, coronal patch poorly developed or absent. Race *griseigularis* has on average paler upperparts, shorter crest, less white in crown, less distinct eyering than nominate, many individuals inseparable; *diversa* is similar to previous, but whiter throat, wingbars less distinct, more extensive coronal patch, olive flanks contrasting with white belly; *urubambae* differs from nominate in paler upperparts, more uniform side of head (without prominent eyering or pale lores), wingbars duller, belly with pale yellow wash, bill slightly heavier; *modesta* is paler and duller overall, wingbars less conspicuous, face dull and almost lacking eyering and contrasting pale lores, has dark centers of otherwise grey crown feathers giving speckled appearance; *chilensis* is dark olive above with bold whitish eyering and lores, pure white coronal patch, yellowish-white wingbars narrow and sharply defined, throat and breast pale olive-grey, becoming white on belly, flanks olive, undertail-coverts yellow. Voice. Call during breeding a burry "feeur" or "feeo", sometimes repeated over and over for long periods, also faster "peeur-peer"; mostly silent at other times, and birds in N Andes less vocal.
Habitat. Scrub, woodland borders, gardens and shrubby areas. Prefers more arid non-forested areas in N part of range, but sometimes at edge of humid, stunted cloudforest. Race *chilensis* breeds in southern beech (*Nothofagus*) forest, deciduous woodland, shrubby hillsides, and clearings with scattered trees or shrubs. During austral winter found in low shrubbery, open woodland, clearings and elfin forest. Sea-level to 3300 m.
Food and Feeding. Insects and berries; also recorded feeding on nectar of introduced *Grevillea robusta*. Sometimes solitary, but will congregate at flowering and fruiting trees. Generally less conspicuous than *E. flavogaster*, often perching upright in dense foliage for periods of time; at other times active and vocal, and sometimes accompanies mixed-species flocks. Perch-gleans and hover-gleans for berries, and also for nectar.
Breeding. Nov-Jan. Nest a well-built cup 8·5 cm in diameter, 5 cm deep, made of vegetable fibres and small twigs, decorated with lichens, lined with plant stems, feathers or thistle down, placed in forked branch of tree or bush; one record of nest in cavity, the only such record for the genus. Clutch 2-3 eggs; incubation and fledging periods not known.
Movements. In N of range largely resident, but probably descending to lower elevations during non-breeding season; race *modesta* moves to interior Peru. S race *chilensis* highly migratory, probably almost entirely so (e.g. no Jun-Jul specimens from Bolivia), spending austral winter throughout C South America, including Amazon Basin; occasional individuals may overwinter in C Chile. Two major migration routes documented: one N-S along E slope of Andes; other from Argentina towards Atlantic coast and N to Brazilian Amazonia, possibly returning S through C Brazil. At least some breeding-season records in Bolivia possibly involve late-returning migrants, rather than breeders. Vagrants recorded in Falkland Is; also, a sight record of an individual flying S half-way between South American mainland and South Shetland Is (off Antarctica).
Status and Conservation. Not globally threatened. Fairly common to locally abundant; appears to be less numerous in N. Occurs in many national parks and other protected areas throughout its range; for example, present in every protected area in forested S part of Argentina and Chile. Given this species' occupancy of secondary habitats and widespread tolerance of converted habitats, it is unlikely to be at any real risk. Furthermore, it is considered an important pollinator for flowering trees (e.g. the proteaceous *Embothrium coccineum*) in *Nothofagus* forest in Chile.

Bibliography. 26. **Small-billed Elaenia**

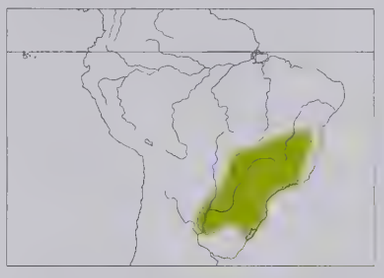
Elaenia parvirostris

French: Élénie à bec court **German**: Dreibinden-Olivtyrann **Spanish**: Fiofío Piquicorto

Taxonomy. *Elainea* [sic] *parvirostris* Pelzeln, 1868, Curitiba, Paraná, Brazil.
Described taxon *E. aenigma* is a synonym of present species. Closely related to *E. albiceps*, and vocalizations are very similar; these two forms have been suggested as perhaps being conspecific, but apparently do not hybridize across a broad area of range overlap in Argentina, although hybridization does occur in a narrow area of overlap in S Bolivia. Reported hybridization between present species and *E. mesoleuca* in SE Brazil (Rio Grande do Sul) is disputed by some authors. Monotypic.
Distribution. Breeds E & SE Bolivia, Paraguay, S Brazil (São Paulo S to Rio Grande do Sul), NE Argentina (S to Buenos Aires) and Uruguay. Migrates N to Amazon Basin and as far as NE Colombia, N Venezuela, Netherlands Antilles, Trinidad and the Guianas.



Descriptive notes. c. 14·5 cm. Small elaenia with white coronal patch and three distinct wingbars. Has narrow whitish eyering, small white coronal patch; rest of top half of head, and entire upperparts, bright olive-green, wings and tail dusky, three whitish wingbars, whitish edging on remiges; throat pure plain grey, breast slightly darker (sometimes with faint olive wash), belly whitish; iris dark brown; bill black, lower mandible flesh-coloured at base, gape bright orange; legs black. Distinguished from very similar *E. mesoleuca* by having white coronal patch, wingbar also on lesser coverts, no strong olive wash on breast; from *E. albiceps* (of race *chilensis*) by extra wingbar, less distinct eyering, slightly shorter bill, but some inseparable. Sexes alike. Juvenile differs from adult in less distinct, yellower wingbars, coronal patch poorly developed or absent. Voice. Song "cher-br", similar to that of *E. albiceps*, also a "chee-oh", and "chit-chit-chea-oh-weet"; dawn song "weedable-we". Calls include many sharp notes; often a soft "cheeu" by migrants in non-breeding season.
Habitat. Variety of woodland and forest habitats, especially edges and openings. Found in towns, gardens, riverine forest, open and deciduous woodland, humid forest edge, open areas with scattered trees. Mostly in lowlands, but occasional breeding records to 2000 m (Bolivia). In austral winter mainly in light woodland, shrubbery and gardens, but also canopy of humid forest and river islands, to 1000 m (slightly higher in Andes).
Food and Feeding. Insects; regularly also small fruits or berries. Perches upright, often in lower levels of shrubs and edge, but also in canopy. Usually solitary, quiet and inconspicuous on wintering grounds, but sometimes several loosely associated in group; also found in mixed-species flocks feeding at termite (Isoptera) swarms. Perch-gleans and hover-gleans insects from foliage, regularly makes short aerial sallies for flying prey.
Breeding. Sept-Mar. Nest a neat cup 6·5 cm in diameter, 5 cm deep, constructed of small twigs and vegetable fibres, entire exterior decorated with mosses, spiderweb and lichens. Clutch 2-3 eggs; incubation 14 days; young fledge in 15 days.
Movements. Highly migratory. Moves N after breeding; spends austral winter (Apr-Oct) across all of Amazonia, mainly in N South America, and as far N as the S Caribbean (Netherlands Antilles, Trinidad).
Status and Conservation. Not globally threatened. Common; widespread in non-breeding season. Occurs in most national parks and other protected areas within its range. Preference for edges and more open woodland, and widespread tolerance of disturbed and converted habitats, make this species unlikely to become threatened in near future.
Bibliography. Babarskas *et al.* (2003), Belton (1985), Brooks *et al.* (1993), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Cueto & López (2002), Di Giacomo (2004), Dubs (1992), ffrench (1991), Fjeldså & Krabbe (1990), Friedmann & Smith (1950), Gunski *et al.* (2000), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Hayes & Samad (2002), Hilty (2003), Hilty & Brown (1986), Hoy (1971), Klimaitis & Moschione (1987), Lanyon (1988b), Lowen *et al.* (1996), Marini & Cavalcanti (1998), Miserendino (1998), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Pearson (1980), de la Peña (1987, 1988, 1995, 1999), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), do Rosário (1996), Schmitt *et al.* (1997), Short (1975), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977, 1982), Wetmore (1926), Zimmer (1941a).

27. **Olivaceous Elaenia**

Elaenia mesoleuca

French: Élénie olivâtre **German**: Schlichttyrann **Spanish**: Fiofío Oliváceo

Taxonomy. [*Muscicapa*] *mesoleuca* Deppe, 1830, Montevideo, Uruguay.
Reported to hybridize with *E. parvirostris* in SE Brazil (Rio Grande do Sul), but this disputed by subsequent authors. Monotypic.
Distribution. SE Brazil (S Goiás and S Bahia S to Rio Grande do Sul), E Paraguay, NE Argentina and N Uruguay.

Descriptive notes. 14-16 cm; 16-20 g. Small elaenia with dark breast, two wingbars. Plumage is dull olive above, whitish eyering, little or no white in crown; wings and tail dusky, wing-coverts tipped yellowish or white, forming two wingbars, remiges narrowly edged whitish; throat dull grey, breast distinctly olive (slight "vested" effect), belly white, flanks and undertail-coverts washed with pale yellow; iris brown; bill black, lower mandible flesh-coloured at base; legs black. Distinguished from very similar *E. parvirostris* most reliably by olive on breast, also by absence of third wingbar (on lesser coverts) and lack of white coronal patch, but many individuals not safely separable. Sexes alike. Juvenile has wingbars less distinct. Voice. Primary call harsh, unmelodious, of 4 notes with pause between first and second, "whik whikiur" or "prrrr, prr-prréé-rrr", has been transliterated as "Frank McQueeter"; also "chirr", and variety of quick single notes such as "pic", "oink" and "wow".
Habitat. Interior of humid tropical and upper tropical forest, including forest borders, gallery forest, woodland, and adjacent clearings, from sea-level to at least 2000 m. Mainly in forest interior; where range overlaps with that of *E. parvirostris*, latter is found mainly in woodland borders.
Food and Feeding. Diet insects and wide variety of small fruits and berries. Generally inconspicuous; perches upright on exposed branches or hidden in foliage in forest canopy or undergrowth. Forages from lower levels to high in canopy, vine tangles, and clearings. Perch-gleans and sallies for insects.
Breeding. Nests found in Dec and Jan; season probably Sept-Apr. Nest a simple cup of loosely packed moss mixed with *Tillandsia* and hyphae of *Marasmius* fungus, exterior decorated with lichens, 4-9 m up in fork of small branch in tree; nest much more coarse and loose than that of *E. parvirostris*, and exterior less extensively decorated. Clutch 2-3 eggs; incubation 15-16 days; chicks fed with both berries and insects, fledge in c. 20 days.
Movements. Probably withdraws into N part of range in austral winter; present in extreme SE Brazil (Rio Grande do Sul) only in Sept-Apr.
Status and Conservation. Not globally threatened. Locally fairly common to common. Common at higher elevations in Itatiaia National Park, in Brazil. Occurs also in several other protected areas, e.g. Caaguazú, San Rafael and Ybycuí National Parks, all in Paraguay, and in Aparados da Serra, Iguaçu and Serra da Canastra National Parks and Mata dos Godoy State Park (Paraná), all in Brazil.
Bibliography. Belton (1985), Brooks *et al.* (1993), Canevari *et al.* (1991), Claramunt & Rocha (2001), Cory & Hellmayr (1927), Cracraft (1985), Di Giacomo (2004), Ferreira de Vasconcelos (2001), Hayes (1995), Lanyon (1988b), López (1997), Lowen *et al.* (1996), Marini & Cavalcanti (1998), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988, 1997), Ridgely & Tudor (1994), do Rosário (1996), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977).

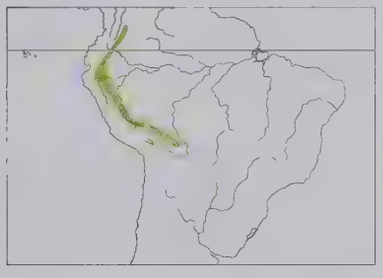
28. **Slaty Elaenia**

Elaenia strepera

French: Élénie bruyante **German**: Schiefertyrann **Spanish**: Fiofío Plomizo

Taxonomy. *Elainea* [sic] *strepera* Cabanis, 1883, foothills of Tucumán, Argentina.
No obvious close relatives within genus. Monotypic.
Distribution. Breeds on E slope of Andes in S Bolivia (S from W Santa Cruz) and NW Argentina; winters in lowlands N to N Venezuela.



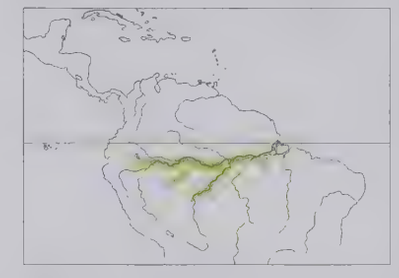
Descriptive notes. 15·5 cm; 18-20 g. Small elaenia with grey plumage, rounded head only slightly crested, tail comparatively long. Male has slate-grey head, slightly paler on cheek, white coronal patch (semi-concealed), narrow white eyering; upperparts slate-grey, wings darker dusky grey, slightly paler edgings on wing-coverts (only indistinct wingbars) and remiges; tail dusky; paler below, throat whitish to pale grey, breast and flanks grey, belly and undertail-coverts whitish; iris dark brown; bill flat and wide, black, basal half of lower mandible flesh-coloured; legs black. Female resembles male, but with olive wash above, more prominent wingbars tinged ochraceous, throat and breast olive-grey, contrasting with yellowish-white belly. Immature is similar to female, but with 3-4 ochraceous wingbars, paler below. Voice. Distinctive call a dry, gravelly "eh-eh-ehhhhhh", unlike that of congeners, more like a frog or locust (Orthoptera) than a bird; silent on passage and in non-breeding quarters.
Habitat. Woodland and forest borders, often along streams at middle elevations, 500-2000 m in breeding season; during migration and austral winter, shrubby openings, forest borders and forest canopy, from sea-level to c. 400 m.
Food and Feeding. Insects, also berries. Generally inconspicuous, often remains in dense foliage, although sometimes sits erect and quietly on open branches for longish periods; often jerks tail. Usually solitary or in pairs; during migration often joins mixed-species flocks in canopy of primary forest. Perch-gleans and hover-gleans; also takes aerial insects by sallying from open perches, then reminiscent of a swallow (Hirundinidae).
Breeding. Oct-Feb. Nest a cup 15 cm in diameter, 3·5 cm in height, of small twigs and leaves, built c. 5 m above ground in crotch of branch. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. Long-distance migrant; spends non-breeding season in N South America, recorded Mar-Sept in N Venezuela. Migrants infrequently recorded, mainly in lowlands of E Colombia (Oct) and E Peru (Sept-Nov); probably occurs as transient in E Ecuador and W Brazil, although not yet recorded in those regions.
Status and Conservation. Not globally threatened. Restricted-range species: present in Argentine and South Bolivian Yungas EBA. Locally common. Common in El Rey National Park, in Argentina. During austral winter, observed in all national parks N to Apurímac, in Peru, and in upper Amazon area. Although the Yungas in La Paz and Cochabamba (Bolivia) are still 90% intact, c. 60% of forests of the Boliviano-Tucumano semi-evergreen zone of S Bolivia and Argentina have been cleared or heavily disturbed, mainly for pasture; large areas in Bolivia also degraded or lost owing to logging, agricultural conversion, colonization and road-building.
Bibliography. Allen (1995), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Hennessey, Herzog & Sagot (2003), Hilty (2003), Hilty & Brown (1986), Joseph (1996), Lanyon (1988b), Marantz & Remsen (1991), Marini & Cavalcanti (1998), McNeil (1982), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (2000), Pearson (1980), de la Peña (1988, 1999), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1977), Zimmer (1941a).

29. **Mottle-backed Elaenia**

Elaenia gigas

French: Élénie écaillée **German**: Schuppenolivtyrann **Spanish**: Fiofío Gigante
Other common names: Giant Elaenia

Taxonomy. *Elainea* [sic] *gigas* P. L. Sclater, 1871, Río Napo, Ecuador.
Possibly most closely related to *E. flavogaster* on basis of voice, behaviour and large crest. Monotypic.
Distribution. E base of Andes from S Colombia (S from W Meta) S to W Bolivia (La Paz, Cochabamba).



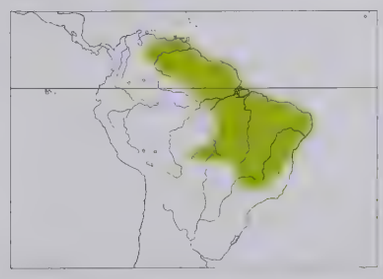
Descriptive notes. 18 cm. Large elaenia with prominent bifurcated crest and large white coronal patch, often looks "horned". Plumage is otherwise olive-brown above, faint whitish eyering; paler green-olive edgings on back (can present mottled or streaked effect); wings dusky, two whitish wingbars, whitish edgings of remiges, tail dusky; throat grey, becoming somewhat streaked or clouded with olive on breast and flanks, belly and undertail-coverts pale yellow; iris dark brown; bill black, flesh-coloured base of lower mandible; legs black. Sexes alike, female slightly smaller. Juvenile undescribed. Voice. Frequent calls a martin-like "direet" and a shrill "pert-chéér"; dawn song "wurdit" or "purdip", given repeatedly from top of low tree or bush.
Habitat. Successional forest habitats in tropical to upper tropical zones, including riparian growth and landslides, man-made clearings in formerly forested areas, willow (*Salix*) and *Tessaria* scrub on river islands, and edges; mainly 250-1250 m, occasionally as high as 1800 m.
Food and Feeding. Insects and small fruits. Perches upright, often on exposed branches, distinctive crest almost always raised; usually appears conspicuous, active and excited, as *E. flavogaster*. Forages at levels of 3-20 m; makes short sallies into air, also hover-gleans.
Breeding. Birds with enlarged gonads in Oct-Nov. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Rare to locally fairly common. Occurs in Tinigua National Park, in Colombia, Podocarpus National Park and Kapawi and Yuturi Lodges, all in Ecuador, and Manu National Park and Biosphere Reserve, in Peru. Possibly extending its range as a result of deforestation.
Bibliography. Chapman (1917c, 1921), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Hennessey, Herzog & Sagot (2003), Hilty & Brown (1986), Lanyon (1988b), Marini & Cavalcanti (1998), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Stotz *et al.* (1996), Traylor (1977), Zimmer (1930, 1941a).

30. **Brownish Elaenia**

Elaenia pelzelni

French: Élénie brune **German**: Brauntyrann **Spanish**: Fiofío Pardo

Taxonomy. *Elaenia pelzelni* Berlepsch, 1907, Lamalonga, Rio Negro, Brazil.
Affinities unknown. Monotypic.
Distribution. R Amazon and larger S tributaries in NE Peru, Brazil and extreme N Bolivia (Pando); sight record in extreme SE Colombia (near Leticia).



Descriptive notes. 18 cm. Distinctive large, dull brownish elaenia. Male has dull brownish head, ear-coverts and face paler brownish, white coronal patch (semi-concealed), inconspicuous whitish eyering and lores; upperparts uniform dull brownish; wings dusky brown, darker than back, all wing-coverts tipped pale (three brownish-white wingbars), remiges edged whitish; tail long, dusky brown; throat white, underparts whitish, breast and flanks washed dingy brownish, undertail-coverts sometimes slightly brownish; iris dark brown; upper mandible black, lower mandible pale flesh-coloured with black tip; legs black. Female lacks coronal patch. Immature has more whitish on wing feathers, rufous wingbars, fulvous underwing and uppertail-coverts, pale-tipped tail. Voice. Calls include variety of burry and clear notes, e.g. low "chick-ert" or "chick-ert-ert" with first note slightly higher, a clearer "chick-urp" or "per-cheet" with second note higher; also, repeated liquid "whit" and high metallic "chick-eep".
Habitat. Riverine forest, especially on river islands, where most often reported in mature stands of tall *Cecropia* on older river islands; also shrubby second growth. To 200 m.
Food and Feeding. No information on diet, but presumably insects and fruits; specialized habitat suggests possible extensive reliance on *Cecropia* fruits. Perches upright, from low levels to high in canopy; rather wary.
Breeding. No information.
Movements. Little information; perhaps local or erratic movements in response to seasonal changes in river levels.
Status and Conservation. Not globally threatened. Locally fairly common. Fairly common in *Cecropia* trees around Iquitos, in Peru. Poorly known species.
Bibliography. Cory & Hellmayr (1927), Forrester (1993), Hennessey, Herzog & Sagot (2003), Lanyon (1988b), Marini & Cavalcanti (1998), Meyer de Schauensee (1982), Pearson (1975), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Zimmer (1941a).

31. **Plain-crested Elaenia**

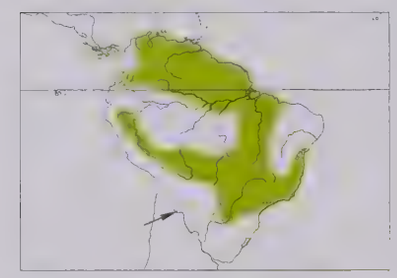
Elaenia cristata

French: Élénie huppée **German**: Braunscheitel-Olivtyrann **Spanish**: Fiofío Crestado

Taxonomy. *Elainea* [sic] *cristata* Pelzeln, 1868, Goiás, Brazil.
Has been hypothesized as being closest to *E. ruficeps* on basis of nostril structure and wing formula, but the two differ greatly in plumage and behaviour. Two subspecies recognized.
Subspecies and Distribution.
E. c. cristata Pelzeln 1868 - Venezuela E of Andes, the Guianas, N, C & E Brazil (S to São Paulo; absent from W & C Amazon Basin) and extreme E Bolivia; isolated populations in SE Colombia (Caquetá, Vaupés), SE Peru (locally in Cuzco and Madre de Dios) and extreme W Bolivia (La Paz).
E. c. alticola J. T. Zimmer & Phelps, Sr, 1946 - tepuis in SE Venezuela (SE Bolívar) and adjacent N Brazil.

Descriptive notes. 14·5 cm; 18 g. Small, very dull elaenia lacking white coronal patch; greatly elongated crown feathers forming conspicuous crest, usually held partially erect and tending to project rearwards. Has head and upperparts uniform dull olive-brown, narrow whitish eyering; wings dusky, two broad whitish wingbars, whitish edgings of remiges, tail dusky; throat greyish-white, becoming greyish-olive on breast, fading to pale yellow on belly and undertail-coverts; iris dark brown; bill black, lower mandible with pale base and brownish tip; legs black. Differs from extremely similar *E. parvirostris* and *E. albiceps* in lack of white in crown, more noticeable crest. Sexes alike. Juvenile undescribed. Race *alticola* is

On following pages: 32. Lesser Elaenia (*Elaenia chiriquensis*); 33. Rufous-crowned Elaenia (*Elaenia ruficeps*); 34. Mountain Elaenia (*Elaenia frantzii*); 35. Greater Antillean Elaenia (*Elaenia fallax*); 36. Highland Elaenia (*Elaenia obscura*); 37. Great Elaenia (*Elaenia dayi*); 38. Sierran Elaenia (*Elaenia pallatangae*); 39. Yellow-bellied Tyrannulet (*Ornithion semiflavum*); 40. Brown-capped Tyrannulet (*Ornithion brunneicapillus*); 41. White-lored Tyrannulet (*Ornithion inerme*); 42. Northern Beardless Tyrannulet (*Camptostoma imberbe*); 43. Southern Beardless Tyrannulet (*Camptostoma obsoletum*); 44. Suiriri Flycatcher (*Suiriri suiriri*); 45. Chapada Flycatcher (*Suiriri islerorum*).



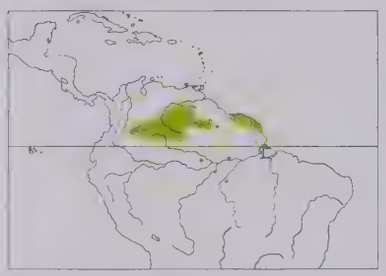
very like nominate. Voice. Infrequent fast, gravelly "jer-jéhjeh", sometimes repeated; dawn song a whistled "chev`a`rear", final note buzzy. Calls include soft melodious "wee", short rattle as "wee`he`he`he`he", low "wheesp" or wheeb", and rising and then falling "dsooty-ééo".
Habitat. Closely tied to open habitats, especially natural savanna vegetation; open park-like savanna woodland (especially with *Curatella* and *Brysonima* trees), scrubby thickets and *cerrado*, locally to1500 m. In SE Peru recorded in arid, rainshadow valley of Andes and along early-successional river margins dominated by *Tessaria*.
Food and Feeding. Insects and berries. Often conspicuously perched, with upright posture, in tops of shrubs or trees, alone or as loosely associated pair. Forages mostly by perch-gleaning or fluttery hover-gleans. Of 54 observed food captures in *Tessaria*-dominated brushy river edges in Peru, 19% involved aerial sallies, 24% upward hover-gleans, 9% downward hover-gleans, 7% upward strikes, 20% perch-gleans; small fruits taken in 20% of cases.
Breeding. No information available on seasonality. Nest a cup of finely woven mosses covered with lichens, lined with plant wool. Clutch 2 eggs; incubation and fledging periods not known.
Movements. Resident in Venezuela. Possibly partially migratory in S Brazil, as numbers fluctuate in Mato Grosso, becoming very common in Aug-Sept; records from Peru may involve migrants.
Status and Conservation. Not globally threatened. Fairly common to locally common; few records from Peru. Likely occurrence in E Colombia requires confirmation. Areas of dry forest are threatened by fires, cattle browsing, selective logging and slash-and-burn cultivation. Nevertheless, the species has a large range and occurs in many national parks and other protected areas, e.g. Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, Noel Kempff Mercado National Park, in Bolivia, and EMBRAPA Experimental Station and Serra da Canastra National Park, both in Brazil; recorded in Manu National Park and Biosphere Reserve, in Peru.
Bibliography. Bates & Parker (1998), Cavalcanti (1988), Chapman (1921), Cory & Hellmayr (1927), Dubs (1992), Fitzpatrick (1980c), Gilliard (1941), Haffer (1974), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Lanyon (1988b), Marini & Cavalcanti (1998), Meyer de Schauensee (1982), Novaes (1978a), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977), Tubelis (2000), Urben-Filho *et al.* (2000), Wetmore (1939), Willis & Oniki (1988c), Zimmer (1941a).

32. Lesser Elaenia

Elaenia chiriquensis

French: Élénie menue **German**: Grauwangen-Olivtyrann **Spanish**: Fiofío Belicoso
Other common names: Chiriqui Flycatcher

Taxonomy. *Elainea* [sic] *chiriquensis* Lawrence, 1865, near David, Chiriquí, Panama.
Probably the mainland ancestor of *E. martinica*. In the past was sometimes treated as conspecific with *E. ridleyana*, but voices very different. Three subspecies recognized.
Subspecies and Distribution.
E. c. chiriquensis Lawrence, 1865 - tropical zone of SW Costa Rica and Pacific slope of W Panama (E to Canal Zone, including Coiba I and Pearl Is).
E. c. brachyptera Berlepsch, 1907 - SW Colombia (Pacific slope in Nariño) and NW Ecuador (Imbabura, Pichincha).
E. c. albivertex Pelzeln, 1868 - Netherlands Antilles (Aruba, Curaçao, Bonaire), Trinidad, N, C & E Colombia, Venezuela, the Guianas, scattered localities throughout N, E & C Brazil (S to São Paulo; apparently absent from upper Amazon Basin), E Peru, N & E Bolivia, Paraguay and NW & NE Argentina.



Descriptive notes. 13·5 cm; 13-18 g. Small, nondescript elaenia, slightly elongated crown feathers producing square-shaped crest. Nominate race has head and upperparts uniform greyish-olive, variably sized white coronal patch (semi-concealed), face slightly paler than upperparts, with narrow whitish eyering; wings and tail dusky, wing-coverts tipped white (two broad wingbars), remiges edged whitish; throat grey, becoming greyish-olive on breast, rest of underparts pale yellow; iris dark brown; bill black, flesh-coloured base of lower mandible; legs black. Differs from *E. flavogaster* in having shorter crest, less yellow below. Sexes alike. Juvenile undescribed. Race *brachyptera* is slightly smaller, with darker, more brownish-olive upperparts, greyer breast; *albivertex* has paler underparts than nominate. Voice. Most common call a clear, whistled "weeééa"; other calls include burry "beer-ta" or "chí-bur" or "jwebu", and a longer "freee" similar to but not so loud, hoarse or excited as that of *E. flavogaster*; also, a low "weeb".
Habitat. Open country; found in dry scrub, *cerrado*, river-island scrub, brushy river margins, grassy areas with scattered bushes and trees, open woodland, second growth, plantations, and cultivated areas with hedgerows. Most common in tropical and upper tropical zones, but locally to 2000 m, and recorded as high as 2800 m.
Food and Feeding. Berries and insects. Forages singly or as pair, in somewhat horizontal posture, more erect when calling, usually at eye-level or higher, and obscured by foliage. Makes aerial sallies and perch-gleans. Behaviour similar to that of *E. flavogaster*, but generally less conspicuous.
Breeding. Mar-Jul, Apr-Jun in Trinidad; occasionally two broods. Nest a small cup, lined with few feathers, 1-4 m up in bush or tree. Clutch 2 eggs; incubation by female, may sing while sitting, period 14-15 days; chicks brooded by female, fed by both parents, fledging period 15-16 days.
Movements. Mostly resident. Those breeding in S Brazil apparently migrate N in austral winter, although non-breeding grounds difficult to delineate, in part because same race (*albivertex*) occurs over enormous range E of Andes. Possibly only a breeding visitor in Trinidad, recorded Mar-Aug.
Status and Conservation. Not globally threatened. Uncommon to common; rather rare in Trinidad. Occurs in many national parks and other protected areas throughout its reasonably large range. Dry forests and scrub threatened by fires, cattle browsing, selective logging and slash-and-burn cultivation; in C Brazil government incentives to drain wet forests also lead to habitat loss. On other hand, this species is tolerant of converted and secondary habitats, and should be secure. In addition, shown to be a very important disperser of seeds of tropical fruiting trees (e.g. the rubiaceous *Palicourea rigida*) in savanna regions, as in Venezuelan *llanos*.
Bibliography. Anon. 33. Rufous-crowned Elaenia

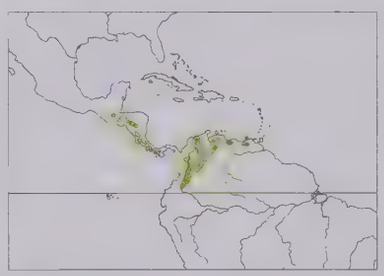
Elaenia ruficeps

French: Élénie tête-de-feu **German**: Rostnacken-Olivtyrann **Spanish**: Fiofío Crestirrufo

Taxonomy. *Elainea* [sic] *ruficeps* Pelzeln, 1868, Borba, Brazil.
Has been hypothesized as being closest to *E. cristata* on basis of nostril structure and wing formula, but the two differ greatly in plumage and behaviour. Monotypic.
Distribution. Very local in SE Venezuela (Bolívar, Amazonas), the Guianas, SE Colombia (Meta E to Guainía and Vaupés) and N Brazil (N Roraima, N Amapá, both sides of middle and lower Amazon, and along R Cururu in S Pará).



Descriptive notes. 14·5 cm; 19 g. Small elaenia with rather distinctive plumage, slight crest. Has semi-concealed rufous patch on crown (sometimes exposed towards back of head, in the field appearing as a "bump"), faint whitish supercilium, narrow and indistinct white eyering; rest of head, and upperparts, dark olive-brown; wings darker dusky, two whitish wingbars, pale edges of remiges; tail short, dusky; mostly pale yellowish below, blurry greyish-olive flammulations on throat, breast and flanks, unstreaked pale yellow belly and undertail-coverts; iris dark brown; bill black, lower mandible with pale flesh-coloured base; legs black. Sexes alike. Juvenile undescribed. Voice. Song an odd, low-pitched jumble or rattle, given singly at irregular and widely spaced intervals, "chu'd'd'd-u!" or "rr-rr'rd'd'dt", ending abruptly; call (Surinam) "d-rr-rr-rr", with quality resembling that of a trogon (Trogonidae) call.
Habitat. Stunted white-sand forest, savanna with scattered bushes and spiny palms, edges of woodland or gallery forest, and *cerrado* thickets, almost always in areas of sandy soil; lowlands, to 1400 m on tepuis in S Venezuela.
Food and Feeding. Insects, also small fruits. Often found in pairs 1-8 m up in vegetation; perches upright at edges or tops of shrubs, from time to time sings from exposed branches under tree canopy. Less conspicuous than most congeners, but often visits fruiting shrubs, occasionally with mixed-species flocks. Perch-gleans and hover-gleans into foliage for insects.
Breeding. Nest found in Aug in French Guiana; birds with enlarged gonads in Feb-Apr in Colombia. One nest described, a cup of twigs and plant fibres, external diameter 8 cm, internal diameter 5 cm, height 5 cm, depth 3 cm, built in palm frond. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon to locally common; range highly fragmented. Occurs in Jaú National Park and Maracá Ecological Station, in Brazil. Sandy-soil habitats have hitherto remained mostly unaffected by humans, as soils do not support agriculture.
Bibliography. Cavalcanti (1988), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Friedmann (1948), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Marini & Cavalcanti (1998), Mayr & Phelps (1967), Meyer de Schauensee (1982), Novaes (1978a), Ridgely & Tudor (1994), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain (1988e), Tostain *et al.* (1992), Traylor (1977), Zimmer & Hilty (1997).

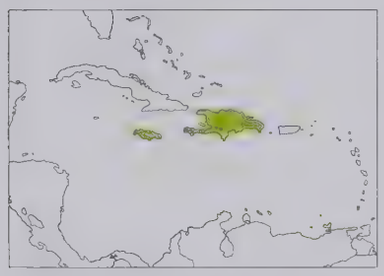
34. Mountain Elaenia

Elaenia frantzii

French: Élénie montagnarde **German**: Nordanden-Olivtyrann **Spanish**: Fiofío Montano

Taxonomy. *Elainea* [sic] *frantzii* Lawrence, 1865, San José, Costa Rica.
Probably forms a superspecies, and sometimes considered conspecific, with *E. obscura*, possibly also including *E. dayi*. Four subspecies recognized.
Subspecies and Distribution.
E. f. ultima Griscom, 1935 - Guatemala, Honduras and El Salvador.
E. f. frantzii Lawrence, 1865 - Nicaragua, Costa Rica and W Panama.
E. f. pudica P. L. Sclater, 1871 - mountains of N Colombia and N Venezuela (except Santa Marta and Perijá), also through E Andes of Colombia into W Venezuela (N to Lara).
E. f. browni Bangs, 1898 - N Colombia (Sierra Nevada de Santa Marta) and NW Venezuela (Sierra de Perijá).

Descriptive notes. 14 cm; 17 g. Medium sized, dull brownish-olive elaenia with rounded head, no coronal patch. Nominate race is olive-brown above, face paler, distinct yellowish eyering; wings dusky, two prominent yellowish wingbars, yellowish edges of remiges; tail dusky olive; pale olive-yellow below, throat slightly paler than breast, slightly yellower on belly; iris dark brown; bill black, pale flesh-coloured base of lower mandible; legs black. Distinguished from *E. pallatangae* by lack of coronal patch, paler belly. Sexes alike, female slightly smaller. Juvenile has brighter, buffy wingbars. Race *pudica* is smaller than nominate, with smaller bill, darker upperparts, paler underparts, wingbars wider; *browni* resembles previous but even smaller, with paler upperparts; *ultima* is darker than nominate, less greenish above, more olive below. Voice. Whistled "peee-oo" or "twee-oo" and more drawn-out "peee-err" or "speeeer"; prolonged dawn song typically a buzzy "d'weet d'weet" or "ch'weet ch'weet", sometimes interspersed with extra gurgling syllables.
Habitat. Open humid to semi-humid forest, forest edge, overgrown clearings, light second growth, hedgerows and farmland areas with scattered bushes and trees. Mainly in mountains at 750-3600 m; breeds at upper extremes of this range.
Food and Feeding. Fruits and insects; possibly more frugivorous than many others of genus. Forages from low to high levels, usually keeping to denser foliage; posture more horizontal than



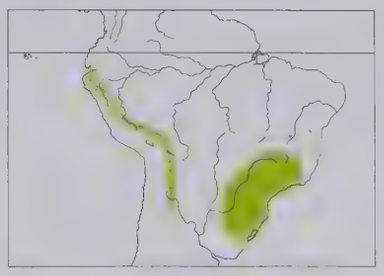
that of many congeners. Perch-gleans and hover-gleans; sometimes flies to ground to glean insects. Gathers in numbers at fruiting trees, and sometimes joins mixed-species foraging flocks.
Breeding. Mar-Nov, but Apr-Jun in Costa Rica; nestlings in Aug in Colombia. Nest built by female, a neat, compact cup of rootlets, mosses, liverworts, often mixed with lichens, inner layer of rootlets and fungal rhizomes, lined with feathers, placed 2-17 m above ground in bush, tree or tall bamboo. Clutch 2 eggs; incubation 15 days; chicks fed by both parents, fledge after 17 days.
Movements. Resident in some areas, but seasonal movements occur, perhaps in response to variations in fruit abundance. In Costa Rica moves to lower levels between Sept and Jan, and becomes uncommon, suggesting emigration (perhaps to S); marked seasonal and local population shifts in Colombia and Venezuela, where may withdraw from higher elevations after breeding.
Status and Conservation. Not globally threatened. Uncommon to very common. The commonest tyrannid in W Chiriquí highlands, in Panama. Occurs in Rancho Naturalista, in Costa Rica, Tambito Nature Reserve, in Colombia, and in most national parks in mountain ranges of Colombia and N Venezuela.
Bibliography. Anon. (1998a), Barrantes & Pereira (2002), Blake (1958), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Komar (2002), Land (1970), Lanyon (1988b), Marini & Cavalcanti (1998), Meyer de Schauensee (1982), Miller (1963), Moermond (1985), Monroe (1968), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Skutch (1967), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Strewe & Navarro (2003), Traylor (1977), Varty *et al.* (1986), Wetmore (1972).

35. Greater Antillean Elaenia

Elaenia fallax

French: Élénie sara **German**: Hispaniolaolivtyrann **Spanish**: Fiofío Canoso
Other common names: Antillean Elaenia

Taxonomy. *Elainea* [sic] *fallax* P. L. Sclater, 1861, Jamaica.
Two subspecies recognized.
Subspecies and Distribution.
E. f. fallax P. L. Sclater, 1861 - Jamaica.
E. f. cherriei Cory, 1895 - Hispaniola.



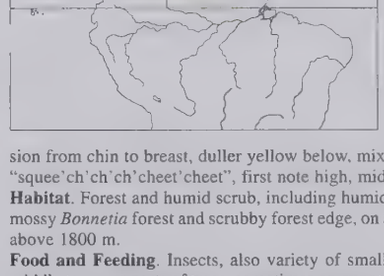
Descriptive notes. 15 cm. Small elaenia with faint eyeline, lightly streaked breast; head appears slightly crested. Nominate race has head and upperparts uniform olive-brown, whitish coronal patch (usually concealed), white or pale yellowish-white loral spot and faint eyering, indistinct narrow dusky eyeline; wings dusky, two whitish wingbars, pale edges of remiges; tail dusky; throat and underparts washed with dull yellow, breast faintly streaked or washed with dull olive; iris dark brown; bill short, black, lower mandible pink with black tip; legs black. Sexes alike, female slightly smaller. Juvenile lacks coronal patch. Race *cherriei* is duller, less brown, above than nominate, much paler below, chin and throat mostly greyish-white. Voice. Harsh "pwee-chi-chi-chiup", "see-ere" or "chewit-chewit", given only in breeding season; dawn song a harsh trill, repeated many times.
Habitat. Humid montane and lowland forest, forest edge, pine (*Pinus*) forest, thickets, and open country with scattered trees; mostly 500-2000 m.
Food and Feeding. Insects and fruits. Frequently forages in pairs, but will join mixed-species flocks. Forages from low levels to high in canopy; sallies to glean insects from leaves and twigs, also hover-gleans for fruits.
Breeding. May-Jun. Nest a moss cup with feather lining, built low in bush to high in tree. Clutch 2 eggs; incubation and fledging periods not recorded.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Jamaica EBA and Hispaniola EBA. Locally common. In Jamaica, 75% of original forest cover already cleared and remaining forest largely second growth; undisturbed forest survives only on high mountain slopes, some of which protected in Blue Mountain and John Crow National Park, but hunting and habitat destruction continue because of lack of funds for effective protection and management; resurgence in coffee cultivation since 1980s led to clearance of much second growth, and other problems include hurricane damage, widespread pesticide use, planting of pines, timber removal, deliberate fires, and continuing conversion for small-scale farming and urbanization. In Hispaniola, Haiti is one of the world's most environmentally degraded countries, with survival forests covering less than 1·5% of the country's area, while only c. 10% of forests remain in Dominican Republic; these continue to be degraded and fragmented by logging, slash-and-burn agriculture, charcoal production, and replacement with pine plantations; only two small national parks exist in Haiti, and c. 22 protected areas (with 15 new areas proposed) covering c. 16% of land area of Dominican Republic, but lack of adequate funding threatens their long-term survival.
Bibliography. Anon. (1998a), Bond (1928a, 1985), Cory & Hellmayr (1927), Dod (1987, 1992), Faaborg (1985), Gochfeld (1985), Keith *et al.* (2003), Lanyon (1988b), Marini & Cavalcanti (1998), Raffaele *et al.* (1998, 2003), Ridgway (1907), Stotz *et al.* (1996), Wetmore & Swales (1931).

36. Highland Elaenia

Elaenia obscura

French: Élénie obscure **German**: Hochland-Olivtyrann **Spanish**: Fiofío Oscuro

Taxonomy. *M[uscipeta] obscura* d'Orbigny and Lafresnaye, 1837, Yungas of Bolivia.
Probably forms a superspecies, and sometimes considered conspecific, with *E. frantzii*, possibly also including *E. dayi*. Two subspecies recognized.
Subspecies and Distribution.
E. o. obscura (d'Orbigny & Lafresnaye, 1837) - E slope of Andes from S Ecuador (Azuay, Loja) S to Bolivia and NW Argentina (S to Tucumán).
E. o. sordida J. T. Zimmer, 1941 - Brazil (S Mato Grosso do Sul E to Minas Gerais, locally to S Bahia, and S to Rio de Janeiro and Rio Grande do Sul), E Paraguay, NE Argentina and N Uruguay.
Descriptive notes. 16 cm; 24-27 g. Large, dark, small-headed elaenia lacking crest and pale coronal patch, appearing short-billed and long-tailed. Considerable individual variation evident in both races. Plumage is uniform dark greyish-olive above, dusky loral spot, narrow whitish eyering; wings dusky, two pale yellowish wingbars, pale edgings of remiges; tail long, dusky, tipped white



when fresh; throat pale yellow, fading to dull olive on breast and flanks, belly pale yellow; iris dark brown; bill black, flesh-coloured base of lower mandible; legs black. Sexes alike, female slightly smaller. Juvenile is dark rufescent brown above, dirty greyish-white below. Race *sordida* is on average larger than nominate, also darker, duller, more olive and less brownish above, less contrast between head and back, darker below, more grey on throat, breast and flanks. Voice. Call (in Andes) a fast "burrrr" or "burrreep"; song (Argentina) a complex phrase, "chee-chooit, chu-wheeo-chu-wee", as from a thrush (Turdidae). In Brazil (*sordida*) also a wren-line "kraaa", like that of a wren (Troglodytidae), and a single-pitched trill.
Habitat. Edges and undergrowth of humid forest and secondary woodland, and stunted cloudforest; often found in forest fragments and in small patches of young second growth. At 1700-3000 m in Andes; sea-level to 2000 m in Brazil.
Food and Feeding. Insects and berries. Often perches upright high in canopy, on outer branches 1-2 m below treetop; usually solitary and inconspicuous, remaining hidden in cover more than most congeners. Sallies up to 1 m above canopy; also perch-gleans and hover-gleans for both insects and berries.
Breeding. Oct-Feb (fledglings in Feb) in Bolivia, mainly Jan in Argentina; nest at end Oct and birds with enlarged gonads in Oct and Nov in Brazil. Nest a simple neat cup 8-9 cm in diameter, 5-6 cm in height, decorated with moss and lichens, interior lined with feathers, in bush or tree. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. None recorded; single record from Bahia (Brazil) could have involved a wanderer outside breeding season.
Status and Conservation. Not globally threatened. Rare to fairly common and local; rare and very local in Ecuador. Can be found in any protected area along E Andean slope from Peru S to NW Argentina; in Brazil, occurs in Serra da Canastra and Caraça National Parks, Intervales State Park and Volta Velha Reserve. Accepts rather disturbed habitats, as well as fragmented habitats.
Bibliography. Belton (1985), Brooks *et al.* (1993), Canevari *et al.* (1991), Chapman (1921), Cory & Hellmayr (1927), Cracraft (1985), Dubs (1992), Fjeldså & Krabbe (1990), Hayes (1995), Herzog *et al.* (1999), Lanyon (1988b), Lowen *et al.* (1996), Marini & Cavalcanti (1998), Meyer de Schauensee (1982), Naka *et al.* (2001), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rocha (2000), do Rosário (1996), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Walker (2001), Willis (1988), Zimmer (1930, 1941a)

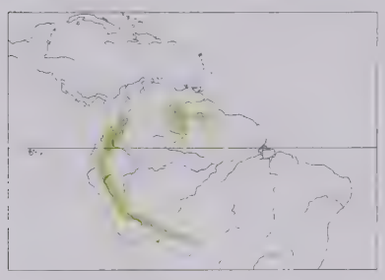
37. Great Elaenia

Elaenia dayi

French: Élénie de Day **German**: Riesenolivtyrann **Spanish**: Fiofío de Day
Other common names: Giant Elaenia; Duida Elaenia (*tyleri*)

Taxonomy. *Elaenia dayi* Chapman, 1929, Cerro Roraima, 8600 feet [c. 2620 m], Venezuela.
Apparently most closely related to *E. obscura* on basis of wing shape and plumage pattern; may be part of superspecies formed by that species and *E. frantzii*. Three subspecies recognized.
Subspecies and Distribution.
E. d. tyleri Chapman, 1929 - mountains of SC Venezuela in Amazonas (cerros Parú, Huachamacari, Marahuaca, Duida) and SW Bolívar (Meseta de Jaua).
E. d. auyantepui J. T. Zimmer & Phelps, Sr, 1952 - Auyán-tepui, in SE Bolívar.
E. d. dayi Chapman, 1929 - mountains and Gran Sabana of SE Venezuela (cerros Ptari-tepui, Chimantá-tepui, Kukenam, Roraima); probably also in adjacent Guyana.

Descriptive notes. 20 cm. Large, dark, long-tailed elaenia with very rounded head, at most only slight crest, and no coronal patch. Plumage is dark sooty brown above, blacker on crown, narrow broken whitish eyering; two dull whitish wingbars, narrow whitish edging on tertials; tail dusky; mostly dull olive-grey below, throat slightly paler, becoming pale yellowish on belly; iris dark brown; bill small, black, pale flesh-coloured base of lower mandible; legs black. Sexes alike, female slightly smaller. Juvenile undescribed. Race *tyleri* is notably larger than nominate; *auyantepui* is smaller and darker than previous, grey suffusion from chin to breast, duller yellow below, mixed with greyish on breast. Voice. Peculiar, loud "squee'ch'ch'ch'cheet'cheet", first note high, middle notes rattling.
Habitat. Forest and humid scrub, including humid forest, open forest, stunted savanna woodland, mossy *Bonnetia* forest and scrubby forest edge, on slopes and summits at 300-2600 m; most records above 1800 m.
Food and Feeding. Insects, also variety of small fruits. Solitary or in pairs. Perches upright in middle to upper parts of trees, sometimes on exposed branches, sometimes within canopy or shrubbery. Perch-gleans and hover-gleans in foliage.
Breeding. Unrecorded.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Rare to fairly common; more numerous at higher elevations, and most common during rainy season on Cerro Roraima (above 2000 m). Most sites lie within national parks. The tepuis within its range are generally inaccessible, and therefore not overly affected by human disturbance, but vegetation is especially sensitive to fire and other disturbances. Gold-prospecting and uncontrolled tourism have recently had severe local impacts.
Bibliography. Chapman (1931), Cory & Hellmayr (1927), Cracraft (1985), Gilliard (1941), Hilty (2003), Lanyon (1988b), Marini & Cavalcanti (1998), Mayr & Phelps (1967), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1977).



38. Sierran Elaenia

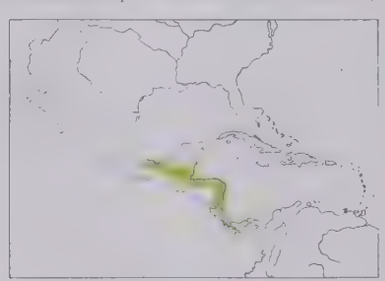
Elaenia pallatangae

French: Élénie de Pallatanga **German**: Sierraolivtyrann **Spanish**: Fiofío de Pallatanga

Other common names: Roraiman Elaenia (*olivina*)

Taxonomy. *Elainea* [sic] *pallatangae* P. L. Sclater, 1862, Pallatanga, Chimborazo, Ecuador.
Apparently closely related to *E. albiceps*; the two possibly hybridize in Ecuador. Geographically remote race *olivina* has been considered a separate species, which may be preferable treatment; position of *davidwillardi* unclear. Five subspecies recognized.
Subspecies and Distribution.
E. p. pallatangae P. L. Sclater, 1862 - Andes of S Colombia and Ecuador.
E. p. intensa J. T. Zimmer, 1941 - Andes of Peru.
E. p. exsul Todd, 1952 - known only from type locality of Incachaca (Cochabamba), in Bolivia.
E. p. olivina Salvin & Godman, 1884 - tepui region of S Venezuela and adjacent N Brazil and Guyana.
E. p. davidwillardi Dickerman & Phelps, Jr, 1987 - Cerro de la Neblina, in extreme S Venezuela (S Amazonas).

Descriptive notes. 14·5 cm; 15-19 g. Small elaenia with rounded head lacking crest, narrow white coronal stripe usually visible. Nominate race is olive above, with yellowish eyering and lores, face with more yellow tinge than upperparts; wings and tail duskier, two conspicuous yellowish-white wingbars, pale edges of remiges; chin whitish, lower throat and breast yellowish-olive, becoming pale yellow on belly and undertail-coverts; iris dark brown; bill black, base of lower mandible flesh-coloured; legs black. Differs from *E. frantzii* in white coronal stripe, yellower underparts; from *E. albiceps* and *E. parvirostris* in yellow coloration below. Sexes alike, female slightly smaller. Juvenile has coronal patch smaller or absent. Race *intensa* is more intensely yellow below, crown less dark, nearer to colour of back; *exsul* is similar to previous, possibly brighter yellow, though this may be due to comparison with faded specimens; *olivina* is browner above, darker and more uniformly olive below, bill somewhat longer; *davidwillardi* is similar to previous, but with upperparts darker olive-brown and underparts brighter. Voice. Call a sharp clear "wheeu", similar to that of *E. albiceps* but lacking burry quality, also abrupt burry "breeyup" or "wree-yr"; in Venezuela (race *olivina*) "pfeéeu".
Habitat. Humid montane forest edge and shrubby clearings, brushy pastures, stunted montane scrub around edges and rocky openings; also second growth dominated by melastomes (Melastomataceae). At 1500-3000 m, locally down to 1000 m and up to 3650 m, in Andes; lower, 900-2400 m, in NE range (*olivina*, *davidwillardi*).
Food and Feeding. Insects; fruits, especially of mistletoes (Loranthaceae) and melastomes, eaten extensively. Less active and conspicuous than congeners; perches quietly and erect for long periods of time, at all levels from understorey to canopy. Often joins mixed-species flocks. Perch-gleans insects in foliage.
Breeding. Birds with enlarged gonads in Jan-Aug in Colombia, Oct-Nov in Peru and Feb-Apr in Venezuela. Nest a neat cup, 1 m up in fork in bush. Clutch 2 eggs; incubation and fledging periods not recorded.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to common; fairly common in Venezuela. In Ecuador, more abundant in S than in N. Occurs in several protected areas, including e.g. Tambito Nature Reserve, in Colombia, Cotacachi-Cayapas Ecological Reserve, Cotopaxi and Podocarpus National Parks, in Ecuador, and Canaíma National Park, in Venezuela; present in every protected area along E Andean slope in Peru and NW Bolivia.
Bibliography. Chapman (1931), Cory & Hellmayr (1927), Cracraft (1985), Davies *et al.* (1994), Dickerman (1987), Dickerman & Phelps (1987), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Marini & Cavalcanti (1998), Mayr & Phelps (1967), Meyer de Schauensee (1982), Miller (1963), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Traylor (1977), Walker (2001), Willard *et al.* (1991), Zimmer (1930, 1941a).



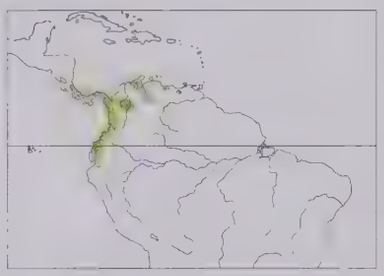
Genus *ORNITHION* Hartlaub, 1853

39. Yellow-bellied Tyrannulet

Ornithion semiflavum

French: Tyranneau à ventre jaune **Spanish**: Mosquerito Ventriamarillo
German: Gelbbauch-Kleintyrann

Taxonomy. *Tyrannulus semiflavus* P. L. Sclater and Salvin, 1860, Choctum, Alta Verapaz, Guatemala.
Formerly placed in a separate genus, *Microtriccus*, together with *O. brunneicapillus*. The two form a superspecies; previously considered conspecific, but now split by most authors on basis of plumage, voice and habitat, also no apparent intergradation where ranges come together in Costa Rica. Monotypic.
Distribution. S Mexico (Veracruz, Tabasco, Chiapas), Guatemala, Belize, Honduras, Nicaragua and Pacific slope of Costa Rica and W Panama (W Chiriquí).



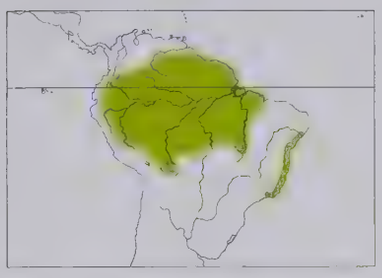
Descriptive notes. 8 cm; 7-8 g. Has white forehead, lores and supercilium; slate-grey crown contrasting sharply with bright olive upperparts; wings and tail dusky olive; auriculars and face olive-brown, entire underparts pure bright yellow, only faintly flammulated with olive on breast and flanks; iris brown; bill compressed laterally, culmen distinctly arched and sharply pointed, black; legs dark grey. Sexes alike. Juvenile has crown and upperparts tinged brownish, underparts paler, throat and breast faintly streaked. Voice. Strong, clear, high-pitched, plaintive "deee" or "peeer", sometimes given as piercing series of 4-6 notes, on even pitch or descending slightly; call note a hard, nasal "biihk-biihk", sometimes repeatedly and interspersed with single "deee" notes; dawn song an incessantly repeated "dee-dee-whi'chu" or somewhat nasal jumble of notes, "t-chee-ee-ee, eee-eee-eet" or "t-chi-ee, pee-pee-pee, t-chi-ee-t-chi-ee…".
Habitat. Humid tropical evergreen forest, forest edge, older second growth, plantations and gardens with tall trees, and tall semi-deciduous scrub; sea-level to 1500 m.
Food and Feeding. Arthropods. Forages singly or in pairs; occasionally joins mixed-species flocks. Actively flits from perch to perch in dense foliage, usually in forest canopy, but descends along edges; mainly perch-gleans from leaves, twigs and stems. Behaviour like that of a parulid warbler or a vireo (Vireonidae).
Breeding. Poorly known. Season probably Mar-Jun. Nest uncertain, possibly globular, placed in camouflaged setting such as in dead *Cecropia* leaf or clump of living bromeliads. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common; probably often overlooked. Occurs in Río Bravo Conservation and Management Area, Columbia River Forest Reserve and Lamanai Archaeological Reserve, all in Belize, Laguna del Tigre National Park, in Guatemala, and Río Negro Jaguar Reserve and Tarcol Lodge, both in Costa Rica.
Bibliography. Anon. (1998a), Blake, E.R. (1953), Brodkorb (1943), Cory & Hellmayr (1927), Eisenmann (1955), González-García (1993), Howell & Webb (1995a), Land (1970), Lee Jones (2004), Meyer de Schauensee (1982), Monroe (1968), Russell (1964), Slud (1964), Smithe (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Traylor (1977).

40. Brown-capped Tyrannulet

Ornithion brunneicapillus

French: Tyranneau à tête brune **Spanish**: Mosquerito Coronipardo
German: Braunkappen-Kleintyrann

Taxonomy. *Tyrannulus brunneicapillus* Lawrence, 1862, Isthmus of Panama.
Formerly placed in a separate genus, *Microtriccus*, together with *O. semiflavum*. The two form a superspecies; previously considered conspecific, but now split by most authors on basis of plumage, voice and habitat, also no apparent intergradation where ranges come together in Costa Rica. Birds from N Colombia (Santa Marta region) and NW Venezuela described as race *dilutum*, supposedly slightly paler below on average, but not reliably distinguishable from other populations. Monotypic.
Distribution. Caribbean slope of Costa Rica S to W & N Colombia, W Ecuador, and locally in W & N Venezuela (E to S Miranda).



Descriptive notes. 8 cm; 7-8 g. Has white forehead, lores and supercilium, brownish-olive to dark brown crown, olive upperparts; wings and tail dusky olive; auriculars and face olive, entire underparts bright yellow, faintly flammulated with olive (especially on breast and flanks); iris brown; bill compressed laterally, culmen distinctly arched and sharply pointed, black; legs dark grey. Sexes alike, female slightly smaller. Juvenile has crown more olive, supercilium less distinct, upperparts browner, wing-coverts with small pale tips, underparts paler. Voice. Series of 4-6 high metallic or piping whistles, each slightly downward-slurred, slight pause after first note, "pee, pey-pey-pew"; also single high-pitched "peeep".
Habitat. Humid tropical and upper tropical evergreen forest, including forest edge and older second growth, also adjacent clearings and plantations; sea-level to 1200 m, mainly below 600 m.
Food and Feeding. Insects. Forages singly or in pairs; occasionally joins mixed-species flocks. Actively flits from perch to perch in dense foliage, usually in forest canopy, also descending lower, especially along edges; mainly perch-gleans from leaves, twigs and stems. Behaviour like that of a parulid warbler or a vireo (Vireonidae).
Breeding. Jan-Aug. Nest an untidy flat saucer of fine twigs, leaf petioles and bark, placed c. 3·5-12 m up on small fork in understorey tree. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common; probably often overlooked. In Venezuela, fairly common on E slope of Andes near Barinitas, and present also in Henri Pittier National Park. Occurs also in Río Claro Reserve and Tayrona National Park, both in Colombia, and Tinalandia Private Reserve and Río Palenque Science Centre, both in Ecuador.

(1953), Chapman (1917c), Cory & Hellmayr (1927), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Slud (1960, 1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Strewe & Navarro (2003), Traylor (1977), Wetmore (1972), Willis (1980), Willis & Eisenmann (1979), Zimmer (1941c).

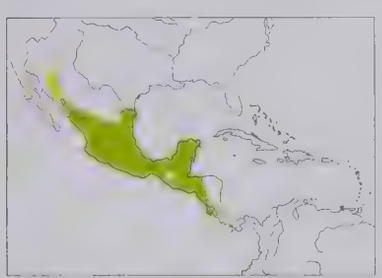
41. White-lored Tyrannulet

Ornithion inerme

French: Tyranneau minute **German**: Weißzügel-Kleintyrann **Spanish**: Mosquerito Moteado

Taxonomy. *O[rnithion] inerme* Hartlaub, 1853, Bahia, Brazil.
Monotypic.
Distribution. E & SE Colombia, S & SE Venezuela and the Guianas S to E Ecuador, E Peru, N Bolivia and N, W, & C Brazil (Amazonia E to E Pará and NW Maranhão); also, apparently isolated coastal population in E Brazil (Alagoas S to Rio de Janeiro).
Descriptive notes. 8 cm; 6-8 g. Has grey to dark grey crown, white lores and broken eyering (meeting over bill to form narrow "spectacle"); upperparts greyish-olive; wings dusky, wing-coverts broadly tipped white (two distinctive wingbars of individual spots), inner remiges narrowly edged pale yellow-green; tail dusky; auriculars and face greyish, throat white, grading to pale olive-yellow on breast, pure pale yellow belly; iris brown; bill compressed laterally, culmen distinctly arched and sharply pointed, black; legs dark grey. Sexes alike, female slightly smaller. Juvenile is duller than adult. Voice. Persistent, piercing series of 4-7 clear piping notes, "peee, dee-dee-deet", sometimes delivered every 5-15 seconds for minutes on end; also single sharp "peeet".
Habitat. Humid tropical and upper tropical evergreen forest, gallery forest, swamp-forest, *várzea* forest, tall white-sand scrub-forest, and mature second growth; in Andean foothills prefers edges and openings, such as treefalls, landslides and barrancas. Sea-level to 1000 m, locally to 1200 m.

Food and Feeding. Arthropods. Forages singly or in pairs; occasionally joins mixed-species flocks. Actively flits from perch to perch in dense foliage, usually in forest canopy, also descending to 2 m along edges and brushy openings in forest; mainly perch-gleans from leaves, twigs and stems. Behaviour like that of a parulid warbler or a vireo (Vireonidae).
Breeding. Birds with enlarged gonads, also juveniles seen, in Dec in Peru. No other information.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common; probably often overlooked. Occurs in many national parks and other protected areas throughout its large range, including e.g. Jaú and Tapajós National Parks, Guaribas (Paraíba) and Sooretama Biological Reserves, Murici Ecological Reserve and Dois Irmãos Ecological Reserve, all in Brazil; Tambopata-Candamo Reserved Zone and Manu National Park and Biosphere Reserve, in Peru; and Pilón Lajas Biosphere Reserve and Amboró, Madidi and Noel Kempff Mercado National Parks, in Bolivia. Accepts reasonably wide range of habitats, including secondary ones; considered unlikely to be at any risk.
Bibliography. Allen (1995), Begazo (1995), Chapman (1931), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Fitzpatrick (1980c), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Meyer de Schauensee (1982), Naka (2004), Oren & Parker (1997), Parker & Remsen (1987), Parker *et al.* (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Roda & Carlos (2003), Schulenberg *et al.* (2001), Scott & Brooke (1985), Sick (1993, 1997), Silveira *et al.* (2003), Snyder (1966), Stotz *et al.* (1996), Teixeira *et al.* (1989), Tostain *et al.* (1992), Traylor (1977), Zimmer (1941c).



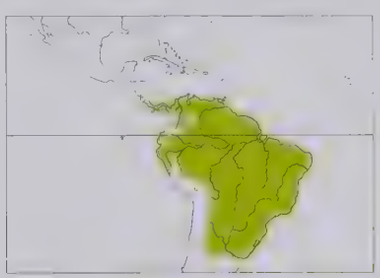
Genus *CAMPTOSTOMA* P. L. Sclater, 1857

42. Northern Beardless Tyrannulet

Camptostoma imberbe

French: Tyranneau imberbe **Spanish**: Mosquerito Imberbe
German: Nördlicher Blasskleintyrann
Other common names: Beardless Flycatcher

Taxonomy. *Camptostoma imberbe* P. L. Sclater, 1857, San Andrés Tuxtla, Veracruz, Mexico.
Forms a superspecies with *C. obsoletum*; the two overlap slightly without intergrading in WC Costa Rica. Birds from S USA (Arizona) and NW Mexico, supposedly longer-billed, more olive above and more yellow below, described as race *ridgwayi*; others, from Cozumel I, named as *thyellophilum* on basis of minute differences in mean culmen length in a small sample; both, however, considered indistinguishable from other populations. Monotypic.
Distribution. S USA (S Arizona, S Texas) and Mexico (including Yucatán Peninsula and islands of Holbox and Cozumel) S to NW Costa Rica.



Descriptive notes. 9·5-10·5 cm; c. 7 g. Pale, drab tyrannulet with slight crest. Plumage is pale greyish-olive above, crown slightly darker, lores and thin broken eyering whitish; wings dusky greyish, wing-coverts and remiges broadly but diffusely edged pale buff to creamy white (two broad wingbars); tail greyish-olive; throat and face greyish-white, grading to pale greyish-olive on breast and clear, very pale yellow to whitish on belly; iris brown; bill long, upper mandible curved and sharply pointed, horn-coloured above, pale flesh-coloured below; legs grey. Sexes alike. Juvenile is yellower below. Voice. Main call a thin but piercing whistle, "fleeeeer", sometimes with thin terminal syllable, "fleeeeee-rit"; also descending series of clear whining notes, "fleee, flee-flee-flee" or "peer-peer-peer".
Habitat. Wide variety of semi-open habitats, including lowland scrub, riparian habitats, brushy savanna, cactus desert, arid thorn-scrub, brushy woodland, tropical deciduous and semi-deciduous forest, cottonwood (*Populus*) groves, mesquite (*Prosopis*), associations with sycamore (*Acer*), live oak (*Quercus*) and mesquite, also second growth, gardens, plantations, and city parks; avoids tall evergreen forest except along roads and other breaks. Mostly below 500 m, but regularly to 1500 m; occasionally to 2100 m.
Food and Feeding. Arthropods; berries and small fruits eaten extensively where available. Forages mainly with active, parulid-style perch-gleaning, flitting rapidly from perch to perch, usually near tips of shrubs and in crowns of trees, also in understorey down to 1 m; often flicks wings and tail nervously. Occasionally hover-gleans, rarely makes aerial sallies.
Breeding. Mar-Aug (to Sept during rainy years) in S USA and Mar-Jun in Middle America; often two broods. Nest bulky, globular, with side entrance sometimes covered by shallow roof, thick-walled, of loosely packed grasses, weed stems, dried leaves, bark and fibres, internal cup padded with soft plant down, fur or feathers; suspended from twigs near outer edge of shrub, or bound with spiderwebs and plant down to stem, in epiphyte or in low palmetto. Clutch 2-3 eggs, rarely 4; incubation and fledging periods not known, but (on partial data) estimated at, respectively, 14-16 days and c. 12 days; incubation and brooding appear to be exclusively by female; both parents attend young; female may begin building second nest while male feeds young at first.
Movements. Populations in extreme N migratory, winter in S portion of breeding range.
Status and Conservation. Not globally threatened. Rare to uncommon in N; more common in S. Overall population estimated at 2,000,000 birds. Survey data for USA suggest no apparent trend between 1966 and 1979, though possibly declining throughout much of N part of range owing to deforestation resulting from farming, cattle-raising and timber extraction; for example, the species is now considered rare in El Salvador following removal of much of its forest habitat; small Texas population threatened by deterioration of riparian forest. Might benefit from creation of further reserves in lowland tropical deciduous forest; as it avoids mature forest, however, it may benefit from light forest disturbance. Fairly common to common from Mexico to Costa Rica; occurs in Río Bravo Conservation and Management Area and Lamanai Archaeological Reserve, both in Belize, and Laguna del Tigre National Park, in Guatemala.
Bibliography. Anon. (1998a), Baicich & Harrison (1997), Bent (1942), Binford (1989), Brodkorb (1943), Brush (1998, 1999b), Contreras (1997), Cory & Hellmayr (1927), DeGraaf & Rappole (1995), Fitzpatrick (1980a), Griscom (1934), Howell & Webb (1995a), Hutto (1992), Kaufman (1996), Land (1970), Lee Jones (2004), Lowery & Dalquest (1951), Monroe (1968), Oberholser (1974), Parkes & Phillips (1999), Paynter (1955), Price *et al.* (1995), Ridgway (1907), van Rossem (1930), Rowley (1962, 1984), Skutch (1997), Slud (1964, 1980), Smithe (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Sutton (1951), Tenney (2000), Thurber *et al.* (1987), Traylor (1977), Udvardy (1963), Wetmore (1943).

43. Southern Beardless Tyrannulet

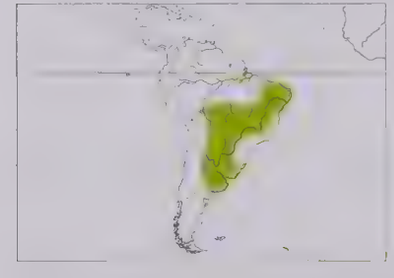
Camptostoma obsoletum

French: Tyranneau passegris **German**: Südlicher Blasskleintyrann **Spanish**: Mosquerito Silbón

Taxonomy. *Muscicapa obsoleta* Temminck, 1824, Curitiba, Paraná, Brazil.
Forms a superspecies with *C. imberbe*; the two overlap slightly without intergrading in WC Costa Rica. Numerous races have been described, many of which weakly defined and intergrade broadly with neighbouring ones. Races form five geographically and morphologically discrete groups, within which the various taxa could arguably be merged: Central American (*flaviventre*, *orphnum*, *majus*), N South American (*pusillum*, *caucae*, *napaeum*), W South American (*sclateri*, *maranonicum*, *griseum*), W Amazonian (*olivaceum*) and C South American (*bolivianum*, *cinerascens*, nominate). Some of these groups possibly merit status of full species; this especially true of extreme W Amazonian *olivaceum*, which sharply bounded on all sides by much paler races and, moreover, is believed to have distinctive vocalizations. Other described races are *venezuelae* (N Venezuela), considered indistinguishable from *pusillum*, and *bogotense* (upper Magdalena Valley, in Colombia), merged with *caucae* as it represents a barely discernible intergrade between that taxon and *pusillum*. Thirteen subspecies recognized.
Subspecies and Distribution.
C. o. flaviventre P. L. Sclater & Salvin, 1865 - Pacific coast of Costa Rica and both coasts of Panama.
C. o. orphnum Wetmore, 1957 - Coiba I, off SW Panama.
C. o. majus Griscom, 1932 - Pearl Is, off S Panama.
C. o. pusillum (Cabanis & Heine, 1859) - N Colombia (Caribbean coast, Magdalena Valley S to Santander), N Venezuela (E to Sucre, S to Táchira, Barinas, Apure, N Amazonas and N Bolívar) and Trinidad.
C. o. caucae Chapman, 1914 - C Colombia (W slope of W Andes, Cauca Valley, upper Magdalena Valley).
C. o. napaeum (Ridgway, 1888) - S Venezuela (Amazonas, SE Bolívar), the Guianas, E Peru, and N Brazil (E Amazonas, Pará, Amapá).
C. o. sclateri (Berlepsch & Taczanowski, 1883) - W Ecuador and extreme NW Peru (Tumbes, N Piura).
C. o. maranonicum Carriker, 1933 - N Peru (extreme E Piura, and middle Marañón Valley in Amazonas, E Cajamarca and E Ancash).
C. o. griseum Carriker, 1933 - arid Pacific coast and slopes of W Peru (Lambayeque S to Lima).
C. o. olivaceum (Berlepsch, 1889) - SE Colombia, E Ecuador, NW Peru and W Brazil (W Amazonas).
C. o. bolivianum J. T. Zimmer, 1941 - C Bolivia (E La Paz, Cochabamba) and NW Argentina (S to Tucuman).
C. o. cinerascens (Wied, 1831) - E Brazil (Maranhão E to Ceará, S to C Mato Grosso and Espírito Santo) and E Bolivia (E Santa Cruz).
C. o. obsoletum (Temminck, 1824) - S Brazil (S Mato Grosso E to Rio de Janeiro, S to Rio Grande do Sul) S to Paraguay, C & NE Argentina (S to La Pampa and Entre Ríos) and Uruguay.

Descriptive notes. 9·5-10·5 cm; 7-9 g. Drab tyrannulet with parulid-like bill, somewhat bushy crest. Nominate race is medium olive-grey above, slightly greyer on crown, crown feathers often elongated with dark centres; lores and thin broken eyering whitish; wings dusky, wing-coverts with broad cinnamon tips (two wingbars), inner remiges broadly edged whitish to creamy white, pale margin of innermost remiges especially wide; throat and face greyish-white, grading to pale yellow on underparts, washed slightly olive on breast; iris brown; bill long, upper mandible curved and sharply pointed, horn-coloured above, pale flesh-coloured below; legs grey. Sexes alike. Juvenile is duller and browner than adult, wingbars duller, pale buffish-white below. Race *bolivianum* is very like nominate but slightly larger; *cinerascens* is slightly paler below, greyer overall; *maranonicum* is smaller and much paler than previous, pale grey-brown with only slight olive tinge above, wingbars and edges of inner remiges slightly to deeply tinged cinnamon-buff, underparts creamy white, warm grey suffusion on breast; *griseum* is also small and pale, somewhat darker than last; *sclateri* differs from previous in having uppertail-coverts dull cinnamon; *caucae* is drab greyish-olive above, crown variably darker, wingbars creamy white to pure white, very pale yellow below, breast distinctly suffused greyish to greyish-olive; *pusillum* is on average slightly smaller than last; *napaeum* is on average slightly darker olive above than previous two; *olivaceum* is distinctive, olive above, crown dark olive, wingbars pale yellow-green to whitish, inner remiges edged bright yellow-green, underparts bright yellow; *flaviventre* is warm greyish-olive above, crown somewhat darker and slightly crested, broad wingbars and broad edges of inner remiges creamy white, underparts deeply suffused with yellow; *majus* is slightly greyer than last, crown slightly lighter, more like back; *orphnum* is extremely small, has very dark crown. Voice. Thin, high whistle, "fleeeeer", rising and falling slightly, sometimes with terminal syllables, "fleeeeee-pit-pit"; also descending series of clear, minor-key notes, "fleee, flee-fleew-fleew"; all loud calls often delivered with crown feathers raised into noticeable crest.
Habitat. Variety of scrub habitats, including cactus desert, arid thorn-scrub, deciduous forest, gallery forest, edges of humid forest, second growth, gardens, city parks, river margins, viny borders of oxbow lakes; generally avoids interior of humid forest, but occasionally found in canopy of *várzea* and swamp-forest. Lowlands, to c. 2000 m; locally to 2800 m, rarely to 3120 m.
Food and Feeding. Insects and spiders; also feeds extensively on berries, e.g. of mistletoes (Loranthaceae), and small fruits. Generally alone or in pairs; sometimes follows mixed-species flocks. Forages mainly with active, parulid-style perch-gleaning, flitting rapidly from perch to perch near tips of shrubs and in crowns of trees, often flicking wings and tail nervously; tail often held slightly cocked, crown feathers often partially raised. Occasionally hover-gleans, rarely makes aerial sallies.
Breeding. Dec-Mar in Middle America and Venezuela, Feb-Apr (also Jul, Oct-Nov) in Trinidad, Sept-Dec in Surinam, Jan-Jun in N Colombia, Jan-Mar in NW Amazonia, Feb-Jun in arid W Ecua-

dor. Aug-Dec in Brazil, Aug-Jan in Argentina and Sept-Feb in Uruguay. Nest, apparently built by female alone, a bulky, globular structure with side entrance, adorned with leaves, grasses, liverworts, twigs, vine tendrils, spiderwebs, wasp-nest material, and cocoon cases, lined with finer material such as seed down; 1-30 m above ground, well concealed and well supported among vines or branches, or suspended from leaf petioles, in one case attached directly to pensile nest of another flycatcher (probably *Tolmomyias flaviventris*); of 20 nests in Ecuador, twelve were placed within 1 m of an active wasp nest. Clutch usually 2 eggs, rarely 3; incubation period 14-15 days; chicks fed by both parents, fledging period c. 17 days.
Movements. Largely resident; not known to be migratory, but populations in extreme S may move N during austral winter.
Status and Conservation. Not globally threatened. Fairly common to very common, and widespread; uncommon and local in some areas (e.g. E Ecuador). Occurs in numerous national parks and other protected areas throughout its very large range. Preference for scrub, lighter woodland and semi-open habitats makes it less susceptible to forest degradation and disturbance than are many other tyrannids; able to exploit converted habitats.
Bibliography. Anon. (1998a), Belton (1985), Brooks *et al.* (1993), Canevari *et al.* (1991), Chapman (1917c, 1926), Chesser (1997), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Di Giacomo (2004), Fitzpatrick (1980c, 1981), Fjeldså & Krabbe (1990), ffrench (1991), Haffer (1975), Haverschmidt (1954, 1968), Haverschmidt & Mees (1994), Hayes (1995), Hayes & Samad (2002), Hilty (1997, 2003), Hilty & Brown (1986), Howell & Webb (1995a), Hudson (1920), Land (1970), Lanyon (1988b), Lowen *et al.* (1996), Marchant (1960), Miller (1963), Miserendino (1998), Narosky & Salvador (1998), Olson (1997), Oren & Parker (1997), de la Peña (1987, 1988), Perry *et al.* (1997), Pople *et al.* (1997), Quiroga *et al.* (1998), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robinson & Terborgh (1997), do Rosário (1996), Salaman (1994), Short (1975), Sick (1993, 1997), Skutch (1981, 1985), Slud (1964), Staicer *et al.* (1996), Stiles & Skutch (1989), Stotz *et al.* (1996), Terborgh *et al.* (1984), Tostain *et al.* (1992), Traylor (1977), Tubelis (2000), Wetmore (1972), White (2002), Williams & Tobias (1994), Willis (1980), Wright *et al.* (1985), Zimmer (1930, 1941b).



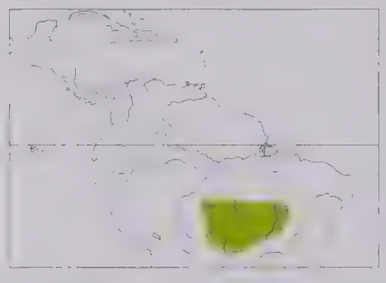
Genus *SUIRIRI* d'Orbigny, 1840

44. Suiriri Flycatcher

Suiriri suiriri

French: Tyranneau suiriri **German**: Grauscheitel-Olivtyrann **Spanish**: Fiofío Suirirí
Other common names: Chaco/Southern Suiriri Flycatcher (*suiriri*); Campo/Northern Suiriri Flycatcher (*affinis*, *bahiae*)

Taxonomy. *Muscicapa suiriri* Vieillot, 1818, Puerto Pinasco, Paraguay.
Genus traditionally placed near *Elaenia* and allies on basis of external morphology, but syringeal data suggest closest to *Ornithion* and allies. Until recently, *S. islerorum* was included as an undescribed form of present species. Races *affinis* and *bahiae* together sometimes treated as a separate species, but former intergrades broadly with nominate in Bolivia; latter suspected by some as being of hybrid origin (following secondary contact of *affinis* with a hypothetical remnant population of ancestral *suiriri* in NE Brazil). Three subspecies recognized.
Subspecies and Distribution.
S. s. affinis (Burmeister, 1856) - Surinam, E Brazil (W Pará, Amapá, and from Maranhão, W Piauí and W Bahia S to most of Mato Grosso, Goiás and São Paulo) and N Bolivia (Beni).
S. s. bahiae (Berlepsch, 1893) - NE Brazil (Paraíba, Pernambuco, NE Bahia).
S. s. suiriri (Vieillot, 1818) - E Bolivia, S Brazil, Paraguay, N & E Argentina and Uruguay.



Descriptive notes. 15·5-16 cm; 11·5-16 g (nominate), 18·5-21 g (*affinis*). Nominate race is mostly grey on crown and back, small white supraloral spot and short supercilium; wings and tail darker, distinct greyish-white wingbars and edges of secondaries, rectrices with pale outer webs and conspicuous pale tips; entirely whitish below, somewhat darker on breast; iris dark brown; bill and legs black. Sexes alike. Juvenile undescribed. Race *affinis* is slightly larger and longer-billed, more olive on back, wing markings more yellowish, paler buffy-yellowish rump and base of tail, throat white, breast pale grey, lower belly and crissum pale yellow; *bahiae* is very similar to previous, but rump and tail base brownish, not pale. Voice. Paired male and female of race *affinis* give different songs in simultaneous duets, male a series of sneezy "pi-chew" notes, variable in length, typically begins with several squeaky notes and ends with several monosyllabic "chew" notes, female a series of loud, squeaky notes similar in quality to introductory notes of male song but higher in frequency and amplitude and more widely spaced, typically decelerating at end; female also gives variety of single-note contact calls that are nasal and have "whiny" quality. All known vocalizations of *bahiae* apparently homologous to nominate, and neither race well documented vocally; most common vocalization a single nasal "rowl" or "jyow".
Habitat. Chaco and open woodland; to 3000 m all year in Bolivian Andes. Race *affinis* restricted to open *cerrado* and *campo* with scattered tall shrubs ("*campo sujo*").
Food and Feeding. Arthropods; also small fruits, e.g. of *Curatella americana*. Perch-gleans items directly from leaf and branch surfaces, hover-gleaning less frequent; aerial hawking for arthropods, by sallying 1-2 m from crown of trees, also less frequent. Recorded as flying 1-3 m from tree down to ground in order to feed on arthropods, especially in recently burnt or very open areas. Less active forager than *S. islerorum*.
Breeding. Oct-Dec in Argentina. Cup-nest constructed of wool, spiderwebs and lichen, external diameter 7 cm, internal diameter 4 cm, height 4-6 cm, internal depth 2·5-3·5 cm, placed 3-6·5 m above ground in tree fork. Clutch 3 eggs; incubation and fledging periods not documented. Brood parasitism by Shiny Cowbird (*Molothrus bonariensis*) recorded.
Movements. Some post-breeding movement to lowland areas in E Bolivia. Nominate race recorded during Aug in Minas Gerais (Brazil), probably a migrant.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Occurs in numerous protected areas, including: Sipaliwini Savanna Nature Reserve, in Surinam; Noel Kempff Mercado National Park and Beni Biosphere Reserve, in Bolivia; San Luis National Park, in Paraguay; Brasília and Serra da Canastra National Parks and EMBRAPA Experimental Station, all in Brazil; and San Juan de Poriahú Private Reserve (in Iberá Provincial Reserve), in Argentina. Large-scale conversion of dry forest and grassland to agriculture is causing significant decline of habitat across Cerrado and Chaco biomes. Greatest threats are posed by conversion for eucalypt (*Eucalyptus*) and pine (*Pinus*) plantations, livestock farming, and large-scale cultivation of soybeans, rice and other exportable crops; outside protected areas few undisturbed tracts remain, and these may soon be degraded by spreading fires and overgrazing, or completely disappear through agricultural expansion. Repeated annual burning of *cerrado* during dry season threatens this habitat; nevertheless, the species has been found in *cerrado* after burning, suggesting some tolerance of frequent fires.
Bibliography. Babarskas *et al.* (2003), Brooks *et al.* (1993), Canevari *et al.* (1991), Cavalcanti (1988), Cory & Hellmayr (1927), Di Giacomo (2004), Dubs (1992), Haffer (1974), Haverschmidt & Mees (1994), Hayes (1995, 2001), Klimaitis & Moschione (1987), Lanyon (1988b), López (1997), Lowen *et al.* (1996), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Novaes (1978a), de la Peña (1987, 1988, 1996), Ridgely & Tudor (1994), Schmitt *et al.* (1997), Schubart *et al.* (1965), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1982), Wetmore (1926), Zimmer, J.T. (1955b), Zimmer, K.J. *et al.* (2001).

45. Chapada Flycatcher

Suiriri islerorum

French: Tyranneau des Isler **German**: Chapadatyrann **Spanish**: Fiofío de la Chapada

Taxonomy. *Suiriri islerorum* K. J. Zimmer *et al.*, 2001, Chapada dos Guimarães, Mato Grosso, Brazil.
Genus traditionally placed near *Elaenia* and allies on basis of external morphology, but syringeal data suggest closest to *Ornithion* and allies. This species was until recently treated as an undescribed form of *S. suiriri*; moreover, unpublished molecular data suggest that it may be more closely related to *Sublegatus* than to latter species. Monotypic.
Distribution. C & SW Brazil (Maranhão, Tocantins, Mato Grosso, Goiás, Mato Grosso do Sul) and extreme E Bolivia (E Santa Cruz).

Descriptive notes. 16 cm; 21-23 g. Crown and back are medium grey, lightly washed olive; small supraloral spot and supercilium white; wings and tail darker, distinct greyish-white wingbars and edges of secondaries, tail proportionally short and broad, feathers with pale outer webs and conspicuous whitish tips; chin, throat and breast whitish, belly and undertail-coverts pure yellow; iris brown; bill black; legs medium grey. Distinguished from similar *S. suiriri* by yellow belly and broader whitish tip to tail, from race *affinis* of that species by shorter and broader bill almost entirely black, darker dorsal surface of tail, white of throat extending up to gape, from race *bahiae* also by darker and less green back, less white breast, paler rump and uppertail-coverts. Sexes alike. Juvenile undescribed. Voice. Paired male and female give different songs in simultaneous duets, male a loud series of paired couplets, a repeated twangy "where where, whooz it", female a loud bubbly rattle of variable length and typically preceded by one or two "whur" notes. Contact call of female of 2-3 syllables, "zhuwheep" or "zhuwheep-oo".
Habitat. Typical *cerrado*, also *campo cerrado* and "*campo sujo*". Highest densities in moderately closed, shrubby areas with relatively large grass component, and with scattered trees 2-5 m tall. Confirmed elevational range 250-750 m; possibly ascends as high as 1200 m.
Food and Feeding. Small arthropods, also fruits. Forages in middle and upper branches of trees, rarely descends to shrubs or the ground. Perch-gleans prey from leaf and branch surfaces, and sallies to vegetation to hover-glean arthropods or fruit; makes occasional short aerial sallies for flying insects. More active than *S. suiriri*.
Breeding. Vocalizing males with enlarged testes and females with well-developed brood patches in late Sept; primary hatching and fledging period probably in Oct. Territorial encounters involve sex-specific duetting and unique stereotypic behaviour from tree crown or bare snag; male flicks wings, and flips tail upwards and fans it, female simultaneously flicks wings and fans tail but tail flipped downwards. No information on nest or other aspects of breeding.
Movements. Resident.
Status and Conservation. Not globally threatened. Rare to locally fairly common. In Mato Grosso, fairly common in shrubby areas with much grass and scattered trees, e.g. along first few km of the Agua Fria road (near Chapada dos Guimarães), and less common in more wooded *cerrado*, e.g. along the Coxipo do Ouro road (near Cuiabá). Average of 1-2 pairs/km in limited roadside surveys. Occurs in Noel Kempff Mercado National Park, in Bolivia, and Chapada dos Guimarães National Park, in Brazil, both of which contain extensive areas of suitable *cerrado* habitat; in Brazil, may also be present in Serra das Araras Ecological Station (W Mato Grosso). Greatest threats to *cerrado* habitats are posed by habitat conversion for eucalypt (*Eucalyptus*) and pine (*Pinus*) plantations, livestock farming, and large-scale cultivation of soybeans, rice and other exportable crops; outside protected areas few undisturbed tracts remain, and these may soon be degraded by spreading fires and overgrazing or completely disappear due to agricultural conversion. Repeated annual burning during dry season, if it stunts shrub recovery, is also a threat. In addition, some areas of suitable habitat are at risk from urbanization, e.g. at the type locality.

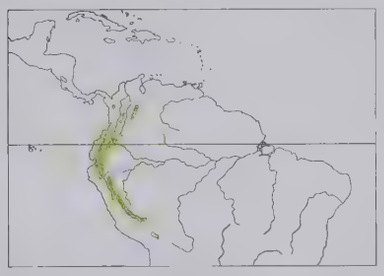
ssp aequatorialis
58
ssp plengei



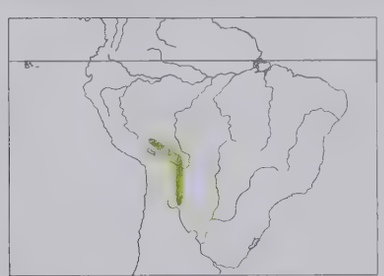
Genus *MECOCERCULUS* P. L. Sclater, 1862

46. White-tailed Tyrannulet

Mecocerculus poecilocercus

French: Tyranneau à queue blanche **Spanish**: Piojito Coliblanco
German: Weißschwanz-Tachurityrann

Taxonomy. *Serpophaga poecilocerca* P. L. Sclater and Salvin, 1873, Púellaro, 8000 feet [c. 2440 m], Pichincha, Ecuador.
Genus as presently constituted is probably polyphyletic, and in need of further study. Syringeal characters suggest that present species and *M. hellmayri*, which form a superspecies, as well as *M. stictopterus*, are possibly close to *Camptostoma*, *Inezia* and relatives. Monotypic.
Distribution. Forested Andes from N Colombia S to SE Peru (S to Cuzco and Madre de Dios).



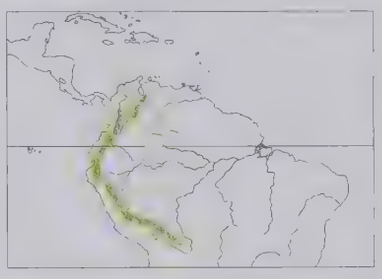
Descriptive notes. 11 cm; 10-11 g. Parulid-like tyrannulet with conspicuous white outer tail feathers. Has thin white supercilium, faint blackish eyestripe, whitish face; medium-grey crown contrasting with greenish-olive upperparts, bright greenish-yellow rump and uppertail-coverts; wings dusky, two white to pale buff wingbars, edges of flight feathers (except near base) pale yellow; tail dusky olive, outermost pair of rectrices mostly or entirely white; throat and underparts greyish-white, faintly washed darker greyish on breast and sides, belly and undertail-coverts yellowish-white; iris brown; bill thin, pointed, black; legs medium grey. Sexes alike, female slightly smaller. Juvenile undescribed. Voice. A series of 3 or 4 clear, downward-slurred notes in minor key, also a single wheezy note.
Habitat. Humid montane evergreen forest, especially mossy cloudforest; recorded at 1400-3050 m, mainly 1800-2400 m. Typically, replaces *M. stictopterus* at lower elevations.
Food and Feeding. Insects; occasionally small fruits. Forages in pairs or in groups of up to six individuals; frequently joins mixed-species flocks. Moves actively, with horizontal posture, often hopping along thinner branches in dense foliage of canopy or middle storey, or in tree-ferns, occasionally low near forest edge. Makes active warbler-like perch-gleans, only occasional upward hover-gleans; regularly fans tail (revealing white outer feathers) and lowers wings (revealing rump patch).
Breeding. Birds with gonads enlarged in Aug and Sept in Colombia. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to common. Apparently more common in Ecuador, where present in many protected areas and easily found along Mindo and Chiriboga roads, W of Quito. Occurs also in Río Abiseo National Park and Machu Picchu Historical Sanctuary, in Peru.
Bibliography. Allen (1998), Chapman (1917c, 1921), Cory & Hellmayr (1927), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Lanyon (1988b), Meyer de Schauensee (1982), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996), Traylor (1977), Walker (2001), Williams & Tobias (1994).

47. Buff-banded Tyrannulet

Mecocerculus hellmayri

French: Tyranneau de Hellmayr **Spanish**: Piojito de los Pinos
German: Fahlbinden-Tachurityrann

Taxonomy. *Mecocerculus hellmayri* Berlepsch, 1907, Cocapata, Cochabamba, Bolivia.
Genus as presently constituted is probably polyphyletic, and in need of further study. Syringeal characters suggest that present species and *M. poecilocercus*, which form a superspecies, as well as *M. stictopterus*, are possibly close to *Camptostoma*, *Inezia* and relatives. Monotypic.
Distribution. Andes from SE Peru (N Puno) S to NW Argentina (Jujuy).



Descriptive notes. 11 cm; 10-11 g. Has thin white supercilium, faint blackish eyestripe, whitish face; medium-grey crown contrasting with greenish-olive upperparts, rump and uppertail-coverts ochraceous olive; wings dusky, two pale buff wingbars, edges of flight feathers (except near base) pale buffy yellow; tail dusky olive; throat and underparts greyish-white, faintly washed darker greyish on breast and sides, belly and undertail-coverts yellowish-white; iris brown; bill thin, pointed, black; legs medium grey. Sexes alike, female slightly smaller. Juvenile resembles adult. Voice. A series of 4 clear, whistled notes, each inflected upwards.
Habitat. Humid montane evergreen forest, especially mossy cloudforest, also *Podocarpus* forest; recorded at 800-2600 m, mainly 1400-2200 m, locally to c. 3000 m. Typically, replaces *M. stictopterus* at lower elevations.
Food and Feeding. Little known. Usually forages alone, often in mixed-species flocks. Moves actively, with horizontal posture, in outer foliage; makes parulid-like perch-gleans and upward hover-gleans.
Breeding. Juvenile in May in Bolivia. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon. Occurs in every protected area in Bolivian Yungas and S to NW Argentina (Calilegua National Park).
Bibliography. Birdsley (2002), Canevari *et al.* (1991), Chebez (1994), Cory & Hellmayr (1927), Cracraft (1985), Di Giacomo & López (2000), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Hennessey, Herzog & Sagot (2003), Lanyon (1988b), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988), Remsen (1984), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1977).

48. White-banded Tyrannulet

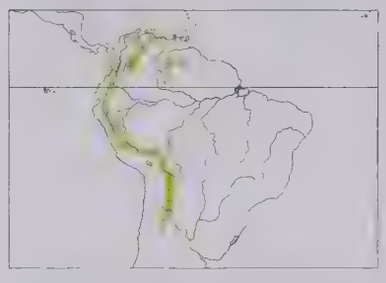
Mecocerculus stictopterus

French: Tyranneau à sourcils blancs **Spanish**: Piojito Alifranjeado
German: Weißbinden-Tachurityrann

Taxonomy. *Elainia stictoptera* P. L. Sclater, 1859, Matus, Chimborazo, Ecuador.
Genus as presently constituted is probably polyphyletic, and in need of further study. Syringeal characters suggest that present species, as well as *M. poecilocercus* and *M. hellmayri*, are possibly close to *Camptostoma*, *Inezia* and relatives. Race *taeniopterus* intergrades with nominate in Peru (E La Libertad). Three subspecies recognized.
Subspecies and Distribution.
M. s. albocaudatus Phelps, Sr & Gilliard, 1941 - Andes of W Venezuela (Trujillo, Mérida, Táchira).
M. s. stictopterus (P. L. Sclater, 1859) - Andes of Colombia, Ecuador (both slopes) and N Peru (Piura, Cajamarca, Amazonas).
M. s. taeniopterus Cabanis, 1874 - E Andes of Peru (S from E La Libertad) S to N Bolivia (La Paz, Cochabamba).

Descriptive notes. 13 cm; 8-11 g. Nominate race has white supercilium, blackish eyestripe, medium-grey crown contrasting with plain dark brownish-olive upperparts; face whitish, bordered posteriorly by indistinct dusky auricular crescent; wings dark dusky, two pure white wingbars, edges of flight feathers (except near base) bright yellow to ochraceous; tail dusky olive; throat and underparts greyish-white, washed greyish on breast and sides, belly whitish, undertail-coverts pale yellow; iris brown; bill long, thin, black, lower mandible sometimes flesh-coloured at base; legs grey. Sexes similar, female on average slightly smaller. Juvenile undescribed. Races differ only slightly: *taeniopterus* has slightly lighter and greener back than nominate, lacking brownish cast, paler grey crown, paler grey wash on breast, less conspicuous ochraceous on secondaries; *albocaudatus* has outermost pair of tail feathers dull buffy white. Voice. Distinctive sharp, rising "squeeyh", sometimes in short series, occasionally interspersed with rapid trill that rises, then falls; dawn song a mix of these calls interspersed with sharper notes.
Habitat. Humid montane evergreen forest, especially mossy cloudforest, stunted elfin forest, alder (*Alnus*) thickets bordering landslides, and temperate brushland near tree-line; recorded at 1900-3600 m, mainly 2300-3300 m. Typically occurs at higher elevations than *M. hellmayri* and *M. poecilocercus*.
Food and Feeding. Insects; occasionally small fruits. Forages in pairs or in groups of 3-5 individuals; frequently joins mixed-species flocks. Forages actively, with horizontal posture, in outer foliage of canopy or middle storey of forest, occasionally low near forest edge. Makes active parulid-like flits, perch-gleans, and upward hover-gleans; regularly hangs in manner of a tit (Paridae) while perch-gleaning.
Breeding. Fledglings in Dec and birds with enlarged gonads in Jan and Aug in Colombia; gonads enlarged in Oct-Nov in SE Peru. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally common; especially common in alder stands. Occurs in many protected areas, including Sierra Nevada National Park, in Venezuela, Puracé National Park and Tambito Nature Reserve, in Colombia, all Andean protected areas in Ecuador and E Peru, and the Yungas of Bolivia.
Bibliography. Allen (1998), Baez *et al.* (1997), Chapman (1917c, 1921), Cory & Hellmayr (1927), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hennessey & Gómez (2003), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Meyer de Schauensee (1982), Remsen (1985), Ridgely (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodewald & Rodewald (2003), Salaman (1994), Smith (1971), Stotz *et al.* (1996), Traylor (1977), Walker (2001), Williams & Tobias (1994), Zimmer (1930, 1940b).

49. White-throated Tyrannulet



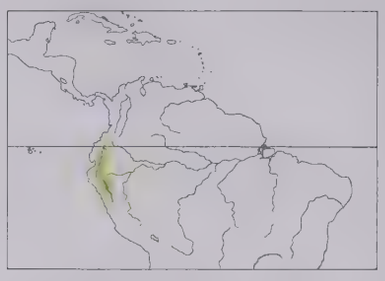
Mecocerculus leucophrys

French: Tyranneau à gorge blanche **Spanish**: Piojito Gargantilla
German: Weißkehl-Tachurityrann

Taxonomy. *M[uscicapa] leucophrys* d'Orbigny and Lafresnaye, 1837, Yanacachi, La Paz, Bolivia.
Genus as presently constituted is probably polyphyletic, and in need of further study. Present species not obviously related to any of forms currently treated as congeners. Race *pallidior* has been suggested as warranting species rank. Species exhibits dramatic "leapfrog" pattern of geographical variation: birds of small size and bearing extremely similar colour patterns occur at N & S ends of range, with much larger and more richly coloured forms in intervening cordilleras. In view of the remarkable differences existing between certain populations that occupy adjacent mountain ridges, several described taxa referring to marginally discernible intermediates are probably better merged with neighbouring forms: *montensis* (Santa Marta Mts, in Colombia) and *pallilitergum* (Venezuelan coastal mountains from Yaracuy E to Miranda) merged with *nigriceps*, and *gularis* (Sierra de Perijá and Mérida Andes, in W Venezuela) with *setophagoides*. Ten subspecies currently recognized.

On following pages: 50. Rufous-winged Tyrannulet (*Mecocerculus calopterus*); 51. Sulphur-bellied Tyrannulet (*Mecocerculus minor*); 52. Black-crested Tit-tyrant (*Anairetes nigrocristatus*); 53. Pied-crested Tit-tyrant (*Anairetes reguloides*); 54. Ash-breasted Tit-tyrant (*Anairetes alpinus*); 55. Yellow-billed Tit-tyrant (*Anairetes flavirostris*); 56. Tufted Tit-tyrant (*Anairetes parulus*); 57. Juan Fernandez Tit-tyrant (*Anairetes fernandezianus*); 58. Agile Tit-tyrant (*Anairetes agilis*); 59. Unstreaked Tit-tyrant (*Anairetes agraphia*).

Subspecies and Distribution.
M. l. notatus Todd, 1919 - W & C Andes of Colombia (S to Cauca).
M. l. setophagoides (Bonaparte, 1845) - E Andes of NW Venezuela (W Zulia and Táchira E to S Lara) and Colombia (Norte de Santander S to Cundinamarca).
M. l. nigriceps Chapman, 1899 - mountains of N Colombia (in Santa Marta region) and N Venezuela (Yaracuy E to Sucre and Monagas).
M. l. roraimae Hellmayr, 1921 - tepui zone of Amazonas (except Cerro Parú and Cerro Duida) and Bolívar, in S & SE Venezuela; also adjacent parts of N Brazil and W Guyana.
M. l. parui Phelps, Sr & Phelps, Jr, 1950 - Cerro Parú, in NC Amazonas (Venezuela).
M. l. chapmani Dickerman, 1985 - Cerro Duida, in C Amazonas (Venezuela).
M. l. rufomarginatus (Lawrence, 1869) - Andes of S Colombia (Nariño), Ecuador and NW Peru (Piura).
M. l. pallidior Carriker, 1933 - W Andes of Peru (Ancash).
M. l. brunneomarginatus Chapman, 1924 - E Andes of Peru (S to Cuzco).
M. l. leucophrys (d'Orbigny & Lafresnaye, 1837) - E Andes from S Peru (S from Cuzco and Madre de Dios) S to N Argentina (Salta, Tucumán).



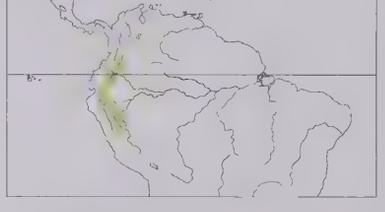
Descriptive notes. 11-14 cm. Nominate race is medium olive-grey above, darker on crown; pure white lores and thin supercilium, dusky face, auriculars with some white feathers; wings brownish-black, two conspicuous broad wingbars medium to dark cinnamon-buff, edges of flight-feathers (except dark basal band) and tips of tertials cinnamon-buff to yellowish-buff; tail dusky brown; throat white, extending to behind auriculars, grey breastband narrow centrally and broad laterally (creating "vest"), rest of underparts medium yellow; iris dark brown; bill long and black; legs black. Sexes alike. Juvenile not described. Race *setophagoides* is larger than nominate, more brownish-grey above, wingbars paler cinammon to creamy buff, belly paler, creamy yellow; *notatus* is like previous but larger, tail longer, upperparts more brownish, wingbars and edges of remiges rich cinnamon-buff, breastband slightly browner; *nigriceps* is much smaller, upperparts strongly tinged olive, crown almost same colour as back, wingbars and edges of remiges nearly white; *roraimae* is also small, much darker above, especially on crown, wingbars more ochraceous; *parui* differs from previous in having upperparts darker brownish, less greyish-olive; *chapmani* has belly richer yellow than last, distinct olive breastband; *rufomarginatus* is significantly warmer, richer brown above, dark sepia-brown crown, wingbars and edges of remiges rich rufous, breastband and upper flanks washed warm brown; *brunneomarginatus* resembles previous, but wingbars and edges of remiges slightly paler rufous, belly much brighter yellow (as yellow as nominate); *pallidior* is paler, more greyish-brown, less olive throughout. Voice. Typical note a singe "pit"; dawn song a musical, warbling series, "whichiry-wichiry-wichiry-chew".
Habitat. Humid upper montane forest and forest edge, stunted cloudforest, elfin forest, brushy ravines at tree-line, shrubby clearings and pastures, *Polylepis* woodland; 1300-4400 m, mainly above 2500 m.
Food and Feeding. Diet predominantly insects and spiders, occasionally small fruits. Forages singly or in pairs, often alone; also regularly joins mixed-species flocks, including small groups containing Giant Conebill (*Oreomanes fraseri*) and Tawny Tit-spinetail (*Leptasthenura yanacensis*) in *Polylepis* woodland. Forages with upright posture, making pauses of 10-30 seconds on open perches 1-4 m from ground, usually under or alongside open vegetation, with tail held nearly vertical (unlike other members of genus); often clings to vertical stems to examine nearby foliage for prey. Sometimes wags tail from side to side. Home range c. 3 ha.
Breeding. Fledglings in Mar and birds with enlarged gonads in Jan-Aug in Colombia; fledglings in Aug-Sept in Ecuador; nests in Dec-Mar in Argentina. Nest a neat cup containing abundant plant fibres, woolly material, moss and spiderwebs, external diameter 7 cm, internal 4 cm, depth 4·5 cm, placed 1·5-4 m above ground on horizontal tree branch, sometimes amid *Tillandsia* clump. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. Resident. Apparently some elevational movement during austral winter.
Status and Conservation. Not globally threatened. Uncommon to very common. Widespread; can be found in any protected area within appropriate elevational zone in its range, although most common in S.
Bibliography. Alabarce & Antelo (1993), Birdsley (2002), Chapman (1917c, 1931), Cory & Hellmayr (1927), Cracraft (1985), Davies *et al.* (1994), Dickerman (1985), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Gilliard (1941), Herzog *et al.* (2002), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Mayr & Phelps (1967), Meyer de Schauensee (1982), Moynihan (1979), Narosky & Salvador (1998), de la Peña (1988), Remsen (1985), Ridgely (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodewald & Rodewald (2003), Salaman (1994), Schulenberg & Servat (2001), Sick (1993, 1997), Smith (1971), Stotz *et al.* (1996), Traylor (1977), Walker (2001), Wetmore (1926), Willard *et al.* (1991), Williams & Tobias (1994), Zimmer (1930, 1940b).

50. **Rufous-winged Tyrannulet**

Mecocerculus calopterus

French: Tyranneau à ailes rousses **Spanish**: Piojito Alirrufo
German: Rotschwingen-Tachurityrann

Taxonomy. *Formicivora caloptera* P. L. Sclater, 1859, Pallatanga, Chimborazo, Ecuador.
Genus as presently constituted is probably polyphyletic, and in need of further study. Syringeal characters suggest that present species and *M. minor* are possibly related to *Phyllomyias*, specifically to *Tyranniscus* if latter resurrected. Monotypic.
Distribution. Andes of W & SE Ecuador and N Peru (S to Lambayeque and La Libertad).
Descriptive notes. 11 cm; 10-11 g. Small parulid-like tyrannulet with rufous on flight-feathers. Has conspicuous white supercilium, broad black line through eye and auriculars, whitish lower face bordered posteriorly by blackish auricular crescent; dark grey crown, contrasting bright greenish-olive upperparts; wings dark dusky, two pure white wingbars, bright rufous edges of flight-feathers (except near base), edges of innermost and outermost remiges yellow; tail dusky olive, with white on two outer pairs; throat and breast pale greyish-white, belly whitish, undertail-coverts pale yellow; iris brown; bill long, thin, black; legs grey. Sexes alike. Juvenile undescribed. Voice. Husky 2-note call, "pur-chee", sometimes with additional notes, "pur-chee, chi-chi-chu", also fast, descending series of emphatic notes, "kew-ki-ke-ke-ku-ku".
Habitat. Humid montane forest, deciduous forest, clearings with scattered trees, and plantations; 400-1950 m, mainly 800-1500 m, occasionally down to 200 m.



Food and Feeding. Insects. Forages alone or in pairs, often with mixed-species flocks. Behaviour like that of parulid warbler, actively flits through outer foliage of small-leafed canopy trees; insects taken mainly with perch-gleans and short hover-gleans.
Breeding. No information.
Movements. Probably resident.
Status and Conservation. Not globally threatened. Rare to uncommon; apparently more numerous on W Andean slopes than on E ones. In Ecuador, occurs in Macquipucuna Reserve, Río Palenque Science Centre and Tinalandia Private Reserve (all in Pichincha), Machalilla National Park (Manabí), Cerro Blanco Forest Reserve and Loma Alta Ecological Reserve (Guayas), Manta Real (Azuay), and Tundo Nature Reserve (in Sozoranga region). Occurs also in Northwest Peru Biosphere Reserve, in Peru.
Bibliography. Carrión & Sibley (1992), Cory & Hellmayr (1927), Davies *et al.* (1994), Lanyon (1988b), Meyer de Schauensee (1982), Parker & Parker (1982), Ridgely (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1977), Williams & Tobias (1994).

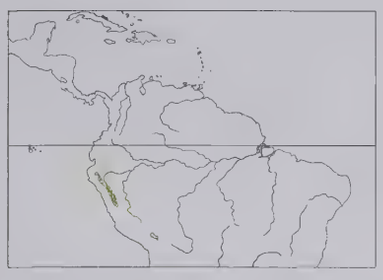
51. **Sulphur-bellied Tyrannulet**

Mecocerculus minor

French: Tyranneau soufré **German**: Gelbbauch-Tachurityrann **Spanish**: Piojito Azufre

Taxonomy. *Leptopogon minor* Taczanowski, 1879, Tambillo, Cajamarca, Peru.
Genus as presently constituted is probably polyphyletic, and in need of further study. Syringeal characters suggest that present species and *M. calopterus* are possibly related to *Phyllomyias*, specifically to *Tyranniscus* if latter resurrected. Monotypic.
Distribution. Andes of W Venezuela (Táchira), and locally in E range in Colombia, E Ecuador (one record from W slope) and N Peru (S to Huánuco).

Descriptive notes. 11·5-12 cm; 11 g. Parulid-like tyrannulet with bright yellow belly. Has thin white supercilium, blackish line through eye, greyish-white face fading to yellowish posteriorly and below; medium-grey crown, contrasting dark olive upperparts; wings dark dusky, two broad buffy wingbars, broad buff edges of flight-feathers (except near base); tail dusky olive, edges of rectrices tinged buffy; upper throat white, otherwise deep yellow below, breast washed with darker olive, belly and undertail-coverts bright yellow; iris brown; bill thin, pointed, black, lower mandible pale at base; legs medium grey. Sexes alike. Juvenile resembles adult. Voice. A series of weak, somewhat nasal, descending notes, "week-week-week-week" or "chew-chew-chew-chew", lasting c. 1 second, sometimes ending with slightly ascending note after a pause; also sharp "weedup" or "weeka" of similar nasal quality.
Habitat. Humid montane forest, especially second growth and broken, patchy cloudforest, clearings with scattered trees; perhaps prefers younger trees. Mainly at 1600-2700 m.
Food and Feeding. Insects; occasionally small fruits. Frequently joins mixed-species flocks. Forages actively, with horizontal posture, in outer foliage; makes frequent parulid-like flits, perch-gleans and hover-gleans.
Breeding. Juveniles in Jul in Ecuador and Aug-Nov in N Peru. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Rare to locally fairly common, perhaps often overlooked; possibly becomes more numerous to S. Seems to favour edge habitats; may be expanding range and becoming more common as a consequence of forest clearance by humans. Occurs in Cueva de los Guácharos National Park, in Colombia, and in all E Andean protected areas in Ecuador and S to Río Abiseo National Park, in Peru.
Bibliography. Birdsley (2002), Cory & Hellmayr (1927), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Krabbe (1992), Lanyon (1988b), Meyer de Schauensee (1982), Ridgely (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996), Traylor (1977).



Genus *ANAIRETES* Reichenbach, 1850

52. **Black-crested Tit-tyrant**

Anairetes nigrocristatus

French: Taurillon à cimier noir **Spanish**: Cachudito Crestinegro
German: Schwarzhauben-Tachurityrann
Other common names: Maranon Tit-tyrant

Taxonomy. *Anaeretes nigrocristatus* Taczanowski, 1884, Chota, Peru.
Genus was long known as *Spizitornis*. Present species forms a superspecies with *A. reguloides*, and the two are often treated as conspecific. Monotypic.
Distribution. Extreme S Ecuador (S Loja) and N Peru (Cajamarca S to E Ancash and Huánuco).
Descriptive notes. 13 cm. Largest and most boldly marked tit-tyrant. Male has central crown feathers greatly elongated into thin, bifurcated crest overlying extensive white crown and nape patch; forehead, entire face and chin black; upperparts black, narrowly streaked white; wings black, wing-coverts broadly tipped white (two bold wingbars), secondaries boldly edged white except at base, white broadest on innermost remiges; tail feathers black, broadly tipped white, white broadest (11-18 mm) on outermost pair, which also has outer web white; throat, breast and flanks streaked black and white, belly and undertail-coverts yellowish-white; iris dark brown; bill bright orange, tip blackish; legs black. Female is similar to male, but crest shorter, front of head duskier black, remaining black-and-white pattern muted into dusky and whitish, bill mainly

black, yellow-orange only at base of lower mandible. Juvenile has crest even shorter, crown dusky, back diffusely streaked blackish and pale olivaceous, buffy lores and partial eyering, underparts dirty white, obscurely streaked dark brown across breast, bill dark with flesh-coloured base of lower mandible. Voice. An explosive, rapid trill, "wheek-tititititititititititit", lasting c. 3 seconds, also shorter version, "wheek-tic tititiit".

Habitat. Arid montane scrub, *Polylepis* woodland, and dense shrubbery bordering streams and ravines; 2300-4200 m, locally down to 2000 m.

Food and Feeding. Insects. Forages alone or in small groups; occasionally follows mixed-species flocks, including those containing *A. parulus*. Active, with frequent short flights from stem to stem near tops of dense to semi-open brush, pausing with horizontal to vertical posture, occasionally flicking tail upwards. Prey captured with perch-gleans, short sallies to hover-glean from leaves and twigs; rarely, in aerial sallies.

Breeding. Season apparently Jun-Jul. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Rare to common, and local. Common in many areas in Peru, e.g. in Calipuy and Huascarán National Parks. Usually less common than *A. parulus* where the two overlap in range.

Bibliography. Best *et al.* (1993), Cory & Hellmayr (1927), Fjeldså (1988), Fjeldså & Krabbe (1990), Lanyon (1988b), Parker *et al.* (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Roy *et al.* (1999), Stotz *et al.* (1996), Traylor (1977), Zimmer (1930, 1940b).

53. Pied-crested Tit-tyrant

Anairetes reguloides

French: Taurillon roitelet **Spanish**: Cachudito Crestiblanco
German: Streifenbauch-Tachurityrann

Taxonomy. *C[ulicivora] reguloides* d'Orbigny and Lafresnaye, 1837, Tacna, Peru.
Genus was long known as *Spizitornis*. Present species forms a superspecies with *A. nigrocristatus*, and often treated as conspecific. Two subspecies recognized.

Subspecies and Distribution.
A. r. albiventris (Chapman, 1924) - WC Peru (Ancash S to Ica and W Ayacucho; single specimen from Apurimac).
A. r. reguloides (d'Orbigny & Lafresnaye, 1837) - SW Peru (S Ayacucho S to Tacna) and extreme NW Chile (Arica).

Descriptive notes. 11·5 cm. Male nominate race has black crown, a few central crown feathers mainly white, many greatly elongated into thin, bifurcated crest overlying extensive white patch on crown and nape; forehead, entire face and chin black; upperparts boldly streaked black and white; wings black, wing-coverts broadly tipped white (two bold wingbars), secondaries boldly edged white except at base, white broadest on innermost remiges; tail black, outer web of outermost pair of rectrices and tip of remaining rectrices white; throat black with fine white streaks (sometimes lacking, perhaps in older males), breast coarsely streaked black and white, streaks stopping abruptly at lower breast but extending somewhat farther down on flanks; belly and undertail-coverts white, tinged pale yellow in fresh plumage; iris dark brown; upper mandible mainly black, lower mandible yellow to orange with blackish tip; legs black. Female is similar to male but crest shorter, forehead, face and throat with fine white streaks or mottling, white crescent under eye, black stripes on back more greyish. Juvenile has crest even shorter, buffy crown patch, dark brown back streaked buffy, buffy lores and partial eyering, underparts light buff, only faint fuscous streaks on breast. Race *albiventris* is difficult to distinguish from nominate, but in fresh plumage has longer crest, broader white crown patch, whiter belly and broader white tips of outer rectrices. Voice. Loud, descending chatter, sometimes preceded by introductory notes, "eek-éék-trrrrrrr"; also descending series of loud whistles.

Habitat. Riparian thickets, arid and semi-arid montane scrub, hedgerows in cultivated areas, shrubby hillsides; sea-level to 3500 m, mostly below 3000 m.

Food and Feeding. Insects. Forages alone or in small groups; occasionally follows mixed-species flocks in company with *A. flavirostris*. Very active, with frequent short flights from stem to stem near tops of dense to semi-open brush, making brief pauses to peer at foliage with horizontal to vertical posture, occasionally drooping wings and flicking tail upwards. Prey captured with perch-gleans, short sallies to hover-glean from leaves and twigs; rarely, aerial sallies.

Breeding. Season Nov-Mar suggested by records of birds with enlarged gonads and of juveniles. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to fairly common. Occurs in Pampa Galeras National Park, in Ayacucho (Peru).

Bibliography. Araya & Chester (1993), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Jaramillo (2003), Johnson (1967), Koepcke (1970), Lanyon (1988b), Marín (2004), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Roy *et al.* (1999), Smith (1971), Stotz *et al.* (1996), Traylor (1977), Zimmer (1930, 1940b).

54. Ash-breasted Tit-tyrant

Anairetes alpinus

French: Taurillon gris **German**: Graubrust-Tachurityrann **Spanish**: Cachudito Pechicenizo

Taxonomy. *Yanacea alpina* Carriker, 1933, Yánac, 15,000 feet [c. 4570 m], Ancash, Peru.
Genus was long known as *Spizitornis*. Present species formerly treated in monotypic genus *Yanacea*, but plumage and molecular evidence suggest close relationship with *A. flavirostris*. Two subspecies recognized.

Subspecies and Distribution.
A. a. alpinus (Carriker, 1933) - W Andean slope in N Peru (Ancash, La Libertad).
A. a. bolivianus (Carriker, 1935) - SE Peru (Cuzco, Apurímac) and NW Bolivia (La Paz).

Descriptive notes. 13 cm; 9-10 g. Nominate race has black central crown feathers greatly elongated into thin, bifurcated crest, large semi-concealed crown patch pure white, forehead and face grey; upperparts dark ashy grey, broadly but diffusely streaked blackish on back; wings black, wing-coverts broadly tipped white (two conspicuous wingbars), secondaries broadly edged white to yellowish-white except at base, innermost remiges broadly edged and tipped white; tail black, outer two pairs of rectrices mostly white; throat and breast grey, fading to yellowish-white on central belly and undertail-coverts; iris hazel to dark brown; bill black, lower mandible sometimes yellow near base, mouth-lining bright yellow or orange; legs and feet black. Sexes alike, female slightly smaller. Juvenile is duller than adult, with shorter crest. Race *bolivianus* has more extensive black on crown, whiter central belly. Voice. Mostly silent; occasionally a whining "eeeh".

Habitat. Semi-humid *Polylepis-Gynoxys* woodland, at 3700-4600 m.

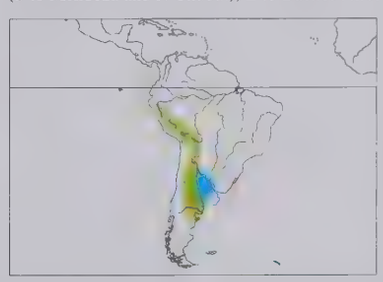
Food and Feeding. Diet not recorded. Forages alone or in pairs; active, making short sallies to hover-glean or perch-glean near tops and outer edges of *Polylepis* shrubs and trees.

Breeding. Juveniles in Mar and Jul in Peru (Cuzco). No other information.

Movements. Resident.

Status and Conservation. ENDANGERED. Restricted-range species: present in Peruvian High Andes EBA and High Andes of Bolivia and Argentina EBA. Rare and very local. Recorded from about twelve mostly unprotected sites in Peru and NW Bolivia. Range severely fragmented; global population thought to number only a few hundred individuals, and each subpopulation extremely small. Usually occurs at very low densities of only 1 pair or family group per *Polylepis* grove. *Polylepis* woodland continues to suffer from cattle grazing, and in many places deliberately set grass fires restrict forest to steep, rocky areas; nevertheless, this species may be able to survive in extremely small habitat patches. Nominate race is very rare in the 3400-km² Huascarán National Park, in Ancash, and small numbers have also been found within Río Abiseo National Park, in La Libertad. In SE Peru, extent of *Polylepis* woodland in Cuzco halved during 1980s, but S race *bolivianus* is still comparatively common in good habitat patches in the Vilcabamba and Vilcanota cordilleras, and total of c. 20-30 individuals exist in several small and widely separated *Polylepis* woodlands of up to 15 ha at Abra Málaga, with small numbers also in isolated forest patches in Machu Picchu Historical Sanctuary (in and near Salcantay massif); relatively common in the Runtacocha highland, Apurímac, where *Polylepis* woodland is mature. Conservation projects and public-awareness campaigns have recently accomplished a slowdown in exploitation of woodland at Abra Málaga. In Bolivia, was found in 1993 and 1996 in several unprotected *Polylepis* groves of less than 100 m² in Choquetanga Valley, on the La Paz-Coroico road; in 1999, discovered also in nearby Cotopata National Park, in small forest patches in three small valleys where very steep slopes have so far been spared from cattle grazing; a BP-sponsored project is now helping to finance further fieldwork and public-awareness campaigns in these areas. These examples illustrate that main threats are heavy grazing and the uncontrolled use of fire, which combine to prevent *Polylepis* regeneration, especially where cutting for timber, firewood and charcoal occurs; changes in stock-rearing, from camelid to sheep and cattle, as well as erosion and soil degradation caused by agricultural intensification, are further adverse factors. This species' conservation status may soon have to be upgraded to Critical, because its small and fragmented population continues to be subject to rapid habitat destruction. Urgent priority is to encourage local people to develop land-use management and restoration schemes that separate agricultural, grazing and forest areas.

Bibliography. Carriker (1933, 1935), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1927), Cracraft (1985), Engblom *et al.* (2002), Fjeldså (1988), Fjeldså & Kessler (1996), Fjeldså & Krabbe (1990), Kessler & Herzog (1998), Lanyon (1988b), Maynard & Waterton (1998), Meyer de Schauensee (1982), Parker & O'Neill (1980), Pulido (1991), Ridgely & Tudor (1994), Smith (1971), Stattersfield & Capper (2000), Stotz *et al.* (1996), Traylor (1977), Vogel & Hennessey (2002), Walker (2001), Wege & Long (1995), Zimmer (1940b).



55. Yellow-billed Tit-tyrant

Anairetes flavirostris

French: Taurillon à bec jaune **Spanish**: Cachudito Piquiamarillo
German: Gelbschnabel-Tachurityrann

Taxonomy. *Anaeretes flavirostris* P. L. Sclater and Salvin, 1876, Tilotilo, Yungas of La Paz, Bolivia.
Genus was long known as *Spizitornis*. Plumage and molecular evidence suggest that present species is closely related to *A. alpinus*. Four subspecies recognized.

Subspecies and Distribution.
A. f. huancabambae (Chapman, 1924) - N Peru (Piura, Cajamarca, E La Libertad, Huánuco).
A. f. arequipae (Chapman, 1926) - SW Peru (S from Lima) S to NW Chile (Arica, Tarapacá).
A. f. cuzcoensis (Chapman, 1924) - SE Peru (Cuzco).
A. f. flavirostris P. L. Sclater & Salvin, 1876 - breeds in high Andes of Bolivia and in W Argentina (S to Mendoza and N Chubut); E to Buenos Aires and Entre Ríos in non-breeding season.

Descriptive notes. 10 cm; 6-7 g. Nominate race has forecrown feathers black and greatly elongated into thin, bifurcated crest overlying large, pure white crown patch; forehead and face dusky grey, faintly streaked white, narrow white supercilium; upperparts medium grey-brown, faintly streaked blackish; wings blackish, wing-coverts broadly tipped cinnamon-buff (two conspicuous wingbars), secondaries broadly edged cinnamon-buff except at base, innermost remiges broadly edged and tipped buffy white; tail dusky brownish, outer web of outermost feather pair and tips of remaining pairs paler; head side, throat and breast white, boldly streaked black, streaks becoming broader on lower breast and upper belly; flanks, lower belly and undertail-coverts unstreaked yellowish; iris dark brown; bill black at tip, yellow on

basal half or two-thirds, mouth-lining orange; legs slate-grey to black. Sexes alike, female slightly smaller. Juvenile is duller and more buffy than adult, with shorter crest. Race *huancabambae* has dark brown back strongly striped blackish, more extensive white in crown, and outer web and tip of outermost rectrices pure white; *cuzcoensis* is larger than other races, with darker brown and more strongly striped back, more heavily and broadly striped breast, least extensive white in crown; *arequipae* has outer web and tip of inner web of outer rectrices dull brownish, only slightly paler than rest of tail, and somewhat less yellowish on belly. Voice. Not especially vocal; a series of piercing notes accented near start, "seet, zwee-ee-seeta-seeta-seeta", and short, descending trill, "tititirrrr", also loud "keer" apparently as alarm.

Habitat. Arid montane scrub, desert scrub, thorn-scrub grassland, semi-arid brush, and semi-humid *Polylepis-Gynoxys* woodland. Mainly 1000-3700 m, occasionally to 4000 m, but recorded down to sea-level in W Peru in non-breeding season.

Food and Feeding. Insects; grass seeds occasionally eaten. Forages alone or in small groups; occasionally with mixed-species flocks, including other species of genus. Very active, with frequent short flights from stem to stem near tops of dense to semi-open brush, making brief pauses to peer at foliage with horizontal to vertical posture, holding wings somewhat drooped, occasionally flicking tail upwards to nearly vertical or over back, and crest raised vertically. Prey captured with perch-gleans, short sallies to hover-glean from leaves and twigs, and, rarely, aerial sallies.

Breeding. Oct-Jan in Argentina; egg in oviduct in Jan, gonads enlarged in Jan-Feb and juveniles seen in Feb in Bolivia. Nest a neat, shallow cup made of plant fibres, thistle down and lichens, lined with feathers, external diameter 4·7 cm, internal 3·5 cm, depth 4·9 cm, placed 1-2 m above ground inside shrubbery. Clutch 2-3 eggs; incubation at one nest at least 13 days; fledging period not documented.

Movements. Populations breeding in extreme S of range apparently migrate N, spending non-breeding season in N & C Argentina (N to Jujuy and Entre Ríos, occasionally E to Buenos Aires); S Andean populations may descend to sea-level in austral winter.

Status and Conservation. Not globally threatened. Fairly common to common. Boundary between breeding and non-breeding ranges in Argentina not clear; further fieldwork required.

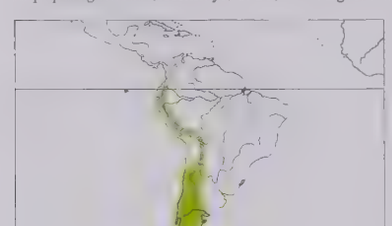
Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Fjeldså & Krabbe (1990), Flores & Capriles (1998), Johnson (1967), Joseph (1996), Koepcke (1970), Lanyon (1988b), Meyer de Schauensee (1982), Mezquida (2002), Narosky & Di Giacomo (1993), Narosky & Salvador (1998), Nellar (1993), Nores *et al.* (1983), de la Peña (1988, 1997, 2001a, 2001b), Ridgely & Tudor (1994), Rocha & Peñaranda (1995), Rocha & Quiroga (1998), Roy *et al.* (1999), Smith (1971), Stotz *et al.* (1996), Traylor (1977), Walker (2001), Wetmore (1926), Zimmer (1930, 1940b).

56. **Tufted Tit-tyrant**

Anairetes parulus

French: Taurillon mésange **German**: Meisentachurityrann **Spanish**: Cachudito Piquinegro

Taxonomy. *Muscicapa Parulus* Kittlitz, 1830, Valparaíso, Chile.



Genus was long known as *Spizitornis*. Molecular data indicate that this species and *A. fernandezianus* form a superspecies. Three subspecies recognized.

Subspecies and Distribution.

A. p. aequatorialis Berlepsch & Taczanowski, 1884 - Andes from S Colombia S to W Bolivia and N Argentina (S to Salta and Jujuy).

A. p. parulus (Kittlitz, 1830) - W Chile (from Atacama) and SW Argentina (from W Neuquén) S to Tierra del Fuego.

A. p. patagonicus (Hellmayr, 1920) - W Argentina (S Mendoza S to N Santa Cruz).

Descriptive notes. 9·5 cm; 6 g. Nominate race has blackish crown, central feathers pure black and greatly elongated into thin, recurved crest, concealed small white crown patch (sometimes absent); forehead dark grey, lores black, curved supraloral patch and rear supercilium white; upperparts dark grey; wings blackish, wing-coverts narrowly tipped white (two thin, rather indistinct wingbars), secondaries faintly edged white to pale yellow, pale colour broadest on innermost remiges; tail dusky, outer web of outermost feather pair and tips of remaining pairs whitish; head side, throat and breast white, finely but boldly streaked dark grey to black, streaks becoming thinner on lower breast and upper belly and extending down flanks; lower breast becoming yellowish, belly and undertail-coverts medium yellow; iris creamy white to pale yellow; bill black; legs black. Sexes alike, female slightly smaller. Juvenile is duller, with shorter crest, no white in crown, slightly buffy wingbars. Races vary only slightly, and all appear much yellower below in fresh plumage than when plumage worn: *aequatorialis* is somewhat browner above, wingbars better defined, breast streaks broader and more extensive; *patagonicus* is more distinctive, paler grey overall, crown greyer, white wingbars broader and more distinct, breast streaks broader and more extensive, underparts paler yellow to whitish. Voice. Very vocal; sharp, high-pitched trills, chatters, and irregular phrases, sometimes in duet, most commonly a series of "chuit" notes speeding up into rapid, chattery, slightly descending trill; contact note a thin "pluit-pluit".

Habitat. Broader ecological range than all congeners. Favours montane shrublands, but also occurs in brushy forest with *Chusquea* bamboo, elfin forest, cloudforest edges, disturbed humid scrub, *Polylepis* woodland, temperate forest, and dry thorn-scrub. Mostly 1800-3500, but to 4200 m in C Andes; sea-level to 2000 m in Chile.

Food and Feeding. Insects. Forages very actively, in pairs or family groups, occasionally with mixed-species flocks but more often not. Makes frequent short flights from perch to perch, preferring small-leafed shrubs; perch-gleans and hover-gleans from vegetation, including flowers and twigs, and occasionally sallies into air. Appears nervous while foraging, often flicking tail upwards and shivering wings, frequently pivoting on perch.

Breeding. Jan-Jun in N and Aug-Jan in S; regularly double-brooded. Often aggressive, chasing with undulating flights while making whirring, rattling sound. Nest a small, compactly built open cup made of root fibres, grass, lichens and thistle down, lined with abundant small feathers, placed in shrub or bamboo, often bordering path, stream or clearing. Clutch mainly 2-3 eggs; incubation and fledging periods not documented.

Movements. S populations (*patagonicus*) migrate N to N Argentina (Salta) after breeding.

Status and Conservation. Not globally threatened. Uncommon to locally common. Occurs in several protected areas, e.g. Puracé National Park, in Colombia, Cotopaxi National Park and Guandera Biological Reserve, both in Ecuador, Machu Picchu Historical Sanctuary, in Peru, and La Campana National Park, in Chile.

Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Chapman (1921), Clark (1986), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Crawshay (1907), Fitzpatrick (1980c), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Flores & Capriles (1998), Harris (1998), Herzog *et al.* (2002), Hilty & Brown (1986), Humphrey *et al.* (1970), Jaramillo (2003), Johnson (1967), Joseph (1996), Lanyon (1988b), Meyer de Schauensee (1982), Narosky & Salvador (1998), Navas & Bó (1991), Nores *et al.* (1983), de la Peña (1987, 1988), Quiroga *et al.* (1998), Remsen (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Roy *et al.* (1999), Smith (1971), Stotz *et al.* (1996), Traylor (1977), Valenzuela (1962), Vuilleumier (1985), Wetmore (1926), Williams & Tobias (1994), Zimmer (1930, 1940b).

57. **Juan Fernandez Tit-tyrant**

Anairetes fernandezianus

French: Taurillon de Juan Fernandez **Spanish**: Cachudito de Juan Fernández
German: Juan-Fernandez-Tachurityrann
Other common names: Masatierra Tit-tyrant

Taxonomy. *Culicivora fernandeziana* R. A. Philippi [Krumwiede], 1857, Juan Fernández Islands, off Chile. Genus was long known as *Spizitornis*. Molecular data indicate that this species and *A. parulus* form a superspecies. Monotypic.

Distribution. Robinson Crusoe I (formerly Más Atierra), in Juan Fernández Is (off Chile).

Descriptive notes. 12·5 cm. A large, dark version of *A. parulus*. Crown is blackish, with central feathers pure black and greatly elongated into very substantial recurved crest overlying a few whitish feathers; forehead and lores black, small supraloral patch and thin rear supercilium white; upperparts dark, dusky grey; wings blackish, wing-coverts narrowly tipped white (two wingbars), secondaries faintly edged white to pale yellow, pale colour broadest on innermost remiges; tail dusky, outer web of outermost feather pair and tips of remaining ones whitish; head side, throat and breast white, boldly streaked black, streaks broadest on breast and upper belly and extending down flanks; lower breast, belly and undertail-coverts creamy white; iris pale yellow; bill black; legs black. Sexes alike, female slightly smaller and with smaller crest. Juvenile undescribed. Voice. Not described; likely to be similar to that of *A. parulus*.

Habitat. All wooded and scrub habitats, including second growth and gardens; sea-level to 900 m.

Food and Feeding. Diet probably insects. Forages actively, in pairs or family groups. Makes frequent short flights from perch to perch; perch-gleans and hover-gleans from vegetation, flowers and twigs, and occasionally sallies into air.

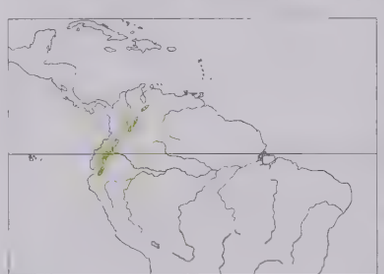
Breeding. Not documented; probably Aug-Dec.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Juan Fernández Islands EBA. Population estimated at 5000 individuals in mid-1980s, and apparently stable. The only insectivorous bird species on the island. Common in undisturbed native woodland, also in luma (*Nothomyrica fernandeziana*) parkland even where understorey has been demolished by introduced mammals such as cattle, pigs, goats and sheep; also in eucalypt (*Eucalyptus*) woodland, and sometimes among other exotic vegetation. Probably suffers some losses from introduced predators such as coatis (*Nasua*), rats (*Rattus*) and cats. Juan Fernández Is were designated as a biosphere reserve in 1977, and Chilean government began a habitat-restoration programme in 1997; the islands have been nominated for World Heritage listing.

Bibliography. Araya & Chester (1993), Brooke (1987), Cory & Hellmayr (1927), Jaramillo (2003), Johnson (1967), Lanyon (1988b), Marín (2004), Ridgely & Tudor (1994), Smith (1971), Stattersfield & Capper (2000), Stotz *et al.* (1996), Traylor (1977), Vuilleumier (1985), Zimmer (1940b).

58. **Agile Tit-tyrant**



Anairetes agilis

French: Taurillon agile **German**: Brauentachurityrann **Spanish**: Cachudito Ágil

Taxonomy. *Euscarthmus agilis* P. L. Sclater, 1856, "Bogotá", Colombia.

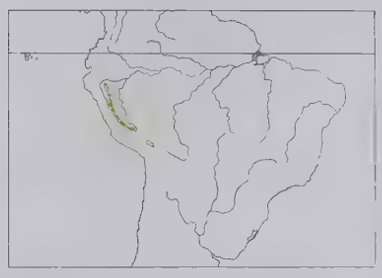
Genus was long known as *Spizitornis*. This species and closely related *A. agraphia* often placed together in a separate genus, *Uromyias*, recognizable on basis of syringeal and plumage characters, but molecular evidence indicates that they are imbedded within present genus. Monotypic.

Distribution. Andes of W Venezuela (Mérida, Táchira), E & C ranges of Colombia, and N Ecuador (S to Cotopaxi on W slope, to N Loja on E slope).

Descriptive notes. 12·5 cm. Streaked flycatcher with flattened black crest and very long, graduated tail. Has brownish-black crown, feathers elongated into bushy, flattened crest, bordered entirely below by white supercilium also consisting of elongated feathers; lores black, broad eyestripe dark brown, face finely streaked black and white; upperparts warm brown, heavily streaked black; wings dark, dusky brown, innermost remiges narrowly edged whitish; tail dusky, outermost rectrices edged white; throat whitish, finely streaked black, underparts pale yellow, heavily but finely streaked blackish except on lower belly and undertail-coverts; iris dark brown; bill black, lower mandible yellow at base; legs dark grey. Sexes alike, female slightly smaller. Juvenile has two buffy wingbars. Voice. A short, chattery trill, sometimes descending slightly and ending in hiccup, "t-t-t-t-t-t-t-t-e-e-e-spew-it!", also single soft chip, and sharp "speew-it!".

Habitat. Upper montane cloudforest and shrubby elfin-forest thickets, with strong preference for mixed or pure stands of *Chusquea* bamboo; 1800-3400 m, mainly above 2700 m.

Food and Feeding. Insects. Forages actively, in pairs or in groups of up to six individuals, almost always with mixed-species flocks, within several metres of ground. Feeds by perch-gleaning and rapid upward strikes; some acrobatic manoeuvres on thin twigs.



Breeding. Birds with enlarged gonads in Feb in Colombia, and fledglings in Dec and Jul in NW Ecuador. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to common. Occurs in Puracé National Park, in Colombia; in Ecuador, occurs in several protected areas on W slope of Andes, and in all national parks except Podocarpus on E slope.
Bibliography. Baez *et al.* (1997), Chapman (1917c), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Meyer de Schauensee (1982), Moynihan (1979), Ridgely (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodewald & Rodewald (2003), Roy *et al.* (1999), Smith (1971), Stotz *et al.* (1996), Traylor (1977), Zimmer (1940b).

59. Unstreaked Tit-tyrant

Anairetes agraphia

French: Taurillon uni **German**: Weißbauch-Tachurityrann **Spanish**: Cachudito Liso

Taxonomy. *Anaeretes agraphia* Chapman, 1919, Idma, 9000 feet [c. 2740 m], Peru.
Genus was long known as *Spizitornis*. This species and closely related *A. agilis* often placed together in a separate genus, *Uromyias*, recognizable on basis of syringeal and plumage characters, but molecular evidence indicates that they are imbedded within present genus. Three subspecies recognized.
Subspecies and Distribution.
A. a. plengei (Schulenberg & Graham, 1981) - N Peru (Cordillera Colán, in C Amazonas).
A. a. squamigerus (O'Neill & Parker, 1976) - C Peru from E La Libertad S to Huánuco.
A. a. agraphia Chapman, 1919 - upper Urubamba Valley (Cordillera Vilcanota), in Cuzco (SE Peru).
Descriptive notes. 12 cm; 10 g. Unstreaked version of *A. agilis*, with very long, graduated tail. Nominate race has crown and nape black, crown feathers elongated into bushy, flattened crest, bordered below by narrow white supercilium, broad dark brown eyestripe, face indistinctly streaked greyish and white; upperparts warm buff-brown, faintly flammulated darker brown; wings dusky brown; tail dusky, outermost rectrices edged white; throat and breast greyish-white, becoming

tinged with yellow on lower breast, breast feathers narrowly edged white (indistinctly scaled appearance), belly creamy white, flanks, lower belly and undertail-coverts pale yellowish-white; iris dark brown; bill black; legs dark grey. Sexes alike, female slightly smaller. Juvenile resembles adult. Race *squamigerus* has breast feathers broadly tipped and edged white, looking more distinctly scaled; *plengei* is much darker than others, olivaceous-brown on upperparts and tail, has breast feathers broadly tipped and edged white, lacks any tinge of yellowish on breast, and rest of flanks and underparts whiter, less yellowish. Voice. Very vocal; high-pitched, explosive "tzrieee", and several disyllabic versions of the same that may extend into short trill, also a chattery trill, wheezy "wheet", single soft "chip", and sharp "kekekeeek!".
Habitat. Upper montane cloudforest and shrubby elfin-forest thickets, with strong preference for mixed or pure stands of *Chusquea* bamboo; 2700-3600 m.
Food and Feeding. Insects. Forages actively, in pairs or in tight groups of up to six individuals, almost always with mixed-species flocks, 1-3 m above ground. Feeds by perch-gleaning, and by rapid upward strikes against lower leaf surfaces or twigs.
Breeding. Fledgling seen in Aug in Huánuco. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Northeast Peruvian Cordilleras EBA. Uncommon and local; possibly often overlooked. Occurs in Río Abiseo and Yanachaga-Chemillén National Parks and in Machu Picchu Historical Sanctuary. The cordilleras in which this species occurs have suffered from widespread deforestation as a result of agricultural cultivation, although cloudforests are still relatively pristine.
Bibliography. Genus *SERPOPHAGA* Gould, 1839

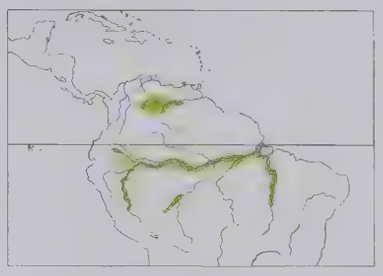
60. Torrent Tyrannulet

Serpophaga cinerea

French: Tyranneau des torrents **German**: Sturzbach-Kleintyrann **Spanish**: Piojito Guardarríos

Taxonomy. *L[eptopogon] cinereus* Tschudi, 1844, Tarma, Junín, Peru.
Possibly closest to *S. nigricans*. Two subspecies recognized.
Subspecies and Distribution.
S. c. grisea Lawrence, 1871 - Costa Rica and W Panama.
S. c. cinerea (Tschudi, 1844) - Andean slopes and foothills from Colombia (including Santa Marta Mts and Perijá Mts) and Venezuela (Mérida) S to Bolivia (La Paz, Cochabamba).



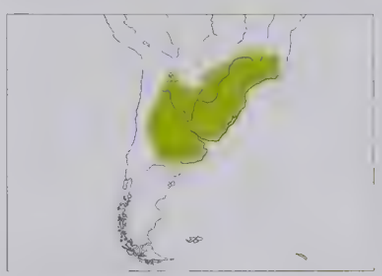
Descriptive notes. 11 cm; 7-8 g. Distinctive, pale grey tyrannulet of rocky torrents. Nominate race has black crown, nape and head side, semi-concealed white crownstripe, pale grey back and rump; wings black, two indistinct narrow whitish wingbars, white edges of innermost remiges; tail black; throat whitish, underparts dirty white, washed greyish on breast and flanks, plain white on lower belly and undertail-coverts; iris dark brown; bill black; legs black. Sexes alike. Juvenile has dark grey head and buffy wingbars. Race *grisea* is considerably smaller and paler than nominate, only small amount of white in crown. Voice. Dawn song a bubbly "chit-chitrrr, chit-chitrrr, chirr, chitrrr" repeated endlessly from atop a rock, frequently interspersed with extra "chit" notes; often gives single, loud "chirt!" while foraging.
Habitat. Most often along rocky margins of fast-flowing mountain streams and rivers surrounded by forest; also amid roots and rubble along banks of slower-flowing rivers near mountains, rarely in reedy marshes or flooded forest (especially *Alnus*) at higher elevations. Mostly 1100-2500 m in Andes, down to 300 m on W slopes in Colombia and Ecuador, and recorded up to 3700 m; in Costa Rica and Panama, 250-1850 m on Caribbean slope and 600-2000 m on Pacific slope, rarely lower (occasionally almost to sea-level). Numbers decline sharply at lower elevations.
Food and Feeding. Insects. Forages alone or in pairs, typically perching on rocks, roots, overhanging branches or riverbanks; makes short, quick sallies to snatch prey in air or against rock tops, mossy rock edges, mud banks and overhanging roots; aerial sallies up to 5 m in distance. Occasionally makes stop-and-go runs along mud bank, picking prey from surface in manner of *Muscisaxicola*, and may wade several centimetres into water. Often flicks or cocks tail upwards while foraging.
Breeding. Jan-Jun in Costa Rica and Panama, May-Sept in Colombia, and Jul probably through Dec in E Peru. Nest (Costa Rica) a substantial open cup composed of fine roots and fibres, entirely covered with moss and selaginella, lined with downy feathers, placed on horizontal branch 1-4 m over fast-flowing rocky stream. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally common; rare in W Peru. Occurs in several protected areas, e.g. Rancho Naturalista, in Costa Rica, Tambito Nature Reserve, in Colombia, Guaramacal National Park, in Venezuela, Machu Picchu Historical Sanctuary, in Peru, and Madidi National Park and Pilón Lajas Biosphere Reserve, both in Bolivia. In some districts it is negatively affected by siltation of watercourses.
Bibliography. Anon. (1998a), Baez *et al.* (1997), Blake (1958), Cory & Hellmayr (1927), Fitzpatrick (1980c, 1985c), Fjeldså & Krabbe (1990), Henderson (2002), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), McLellan (1938), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Salaman (1994), Slud (1964), Skutch (1960, 1985), Smith (1971), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Traylor (1977), Traylor & Fitzpatrick (1982), Varty *et al.* (1986), Wetmore (1972), Young & Zook (1999), Zimmer, J.T. (1930, 1940b), Zimmer, K.J. & Whittaker (2000).

61. River Tyrannulet

Serpophaga hypoleuca

French: Tyranneau des rivières **German**: Uferkleintyrann **Spanish**: Piojito Ribereño

Taxonomy. *Serpophaga hypoleuca* P. L. Sclater and Salvin, 1866, near Sarayacu, lower Río Ucayali, Peru.
Race *venezuelana* possibly indistinguishable from and synonymous with *pallida*, but paucity of specimens precludes definitive study. Three subspecies recognized.
Subspecies and Distribution.
S. h. venezuelana J. T. Zimmer, 1940 - R Orinoco and tributaries in extreme E Colombia and C Venezuela.
S. h. hypoleuca P. L. Sclater & Salvin, 1866 - SE Colombia, E Ecuador, E Peru, W Amazonian Brazil and N Bolivia.
S. h. pallida E. Snethlage, 1907 - lower Amazon and lower R Tapajós and R Tocantins, in EC Brazil.
Descriptive notes. 10·5 cm; 5·5-6·7 g. Slender, grey tyrannulet of river-island scrub. Nominate race has grey forehead, black mid-crown, central crown feathers elongated to form flat crest partially concealing white coronal patch; lores and partial lower eyering white; upperparts uniformly brownish-grey, wings unmarked dusky brownish-grey; tail long, dusky; lower face, chin and entire underparts white, tinged pale grey across breast; iris dark brown; bill black; legs dark grey. Sexes alike. Juvenile is like adult. Race *venezuelana* is smaller than nominate, paler, less black on crown, white crown patch smaller, virtually lacks crest; *pallida* is paler overall, less black on crown, greyish tinge on breast virtually lacking, bill shorter. Voice. Excited, slightly rising rattle preceded by 2-note phrase accented on second note, "chip-skéép-pf-t-t-t-t-t-t-et-et-et-chip-chip" or "d-d-d-r-r-re-re-re-reet?"; partners in duet sing rapid "p'dit-p'dit-p'dt" or "pikup, pikup, pikup"; also thin, weak "see-blik" or "pit-chick" while foraging.



Habitat. Mainly low, sparse, early-successional scrub along large river margins and islands, also seasonally flooded savanna; sea-level to 200 m, locally to 600 m.
Food and Feeding. Small insects. Forages alone, or in pairs or family groups. Active, reminiscent of a gnatcatcher (*Polioptila*), restlessly moving about with horizontal posture through shrubs and sapling trees. Techniques mostly perch-gleaning, occasionally sallying short distances (less than 1 m) to hover-glean prey from leaf surfaces; rarely, aerial sallies. Resting posture more upright.
Breeding. Jun-Oct in Colombia; fledgling in Jul and nest in Oct in Venezuela. Nest a delicate, tightly constructed open cup, outer diameter 4·5 cm, inner diameter 3·2 cm, height 3·5 cm, made of fine grass, with spiderwebs woven in (especially at attachment points), lined with large feathers, placed 0·5 m up in fork between main stem and major branch of low shrub. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. Resident; may move seasonally with changes in water level.
Status and Conservation. Not globally threatened. Rare to fairly common, but local. In Venezuela, fairly common at Hato Cedral and Hato El Frio (W Apure), and on river islets near Porto Ayacucho (NW Amazonas). Occurs near Jatun Sacha and Kapawi Lodges, both in Ecuador, in Manu National Park and Biosphere Reserve, in Peru, and in Mamirauá Reserve (Amazonas), in Brazil.
Bibliography. Cory & Hellmayr (1927), Cracraft (1985), Cruz & Andrews (1989), Friedmann (1948), Hennessey, Herzog & Sagot (2003), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Meyer de Schauensee (1982), Pacheco (1995), Pearson (1975), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rojas *et al.* (1997), Sick (1993, 1997), Smith (1971), Stotz *et al.* (1996), Traylor (1977), Zimmer (1940b).

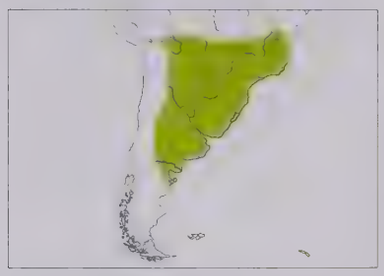
62. Sooty Tyrannulet

Serpophaga nigricans

French: Tyranneau noirâtre **German**: Rußkleintyrann **Spanish**: Piojito Gris

Taxonomy. *Sylvia nigricans* Vieillot, 1817, Paraguay.
Possibly closest to *S. cinerea*. Includes "*S. araguayae*" . Monotypic.
Distribution. S Bolivia (Tarija), Paraguay and SE Brazil (S from Minas Gerais and Espírito Santo) S to C Argentina (S to Río Negro) and Uruguay.

Descriptive notes. 12 cm; 9 g. Plumage is uniformly dark grey to brownish-grey above, crown slightly darker, semi-concealed white crownstripe; wings dusky grey, two indistinct paler grey wingbars, innermost remiges edged pale grey to whitish; tail black; chin whitish, underparts uniform pale grey, paler than back, flanks tinged more brownish posteriorly; iris dark brown; bill black; legs black. Sexes alike. Juvenile undescribed. Voice. Song a few staccato notes, followed by higher, sweet, "canary-like" notes.
Habitat. Almost always near water, most often along rocky or brushy margins of streams and rivers, also along irrigation ditches, farm ponds, and brushy pastures with standing water; occasionally in patches of brush and even woodland some distance from water. Sea-level to 1000 m.
Food and Feeding. Insects. Very active, restlessly flitting from perch to perch on rocks or branches, rarely to ground. Sallies into air, to ground and to water surface to snatch insects. Regularly pumps tail up and down, sometimes fans it while doing so.
Breeding. Oct-Dec. Nest, built by both sexes, a tightly woven open cup or basket up to 10 cm deep, 4 cm wide, of roots and grasses, lined with feathers, suspended from branch, twig or root and often under overhang, including artificial structure (e.g. bridge). Clutch 3 eggs; incubation and fledging periods not recorded. Occasionally parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Uncertain; apparently resident over most of range, but populations in extreme S possibly migrate N after breeding.
Status and Conservation. Not globally threatened. Uncommon. Occurs in many national parks and other protected areas throughout its range, e.g. Ybycuí National Park, in Paraguay, Aparados da Serra, Iguaçu and Serra da Canastra National Parks, all in Brazil, and Iguazú National Park and San Juan de Poriahú Private Reserve (in Iberá Provincial Reserve), both in Argentina. Given its tolerance of converted habitat and its reasonably large range, this species is not considered to be at any risk.
Bibliography. Babarskas *et al.* (2003), Barrows (1883), Belton (1985), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Fjeldså & Maijer (1996), Friedmann (1927), Hayes (1995), Klimaitis & Moschione (1987), Lanyon (1988b), Meyer de Schauensee (1982), Mohr *et al.* (2000), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores & Yzurieta (1984), Nores *et al.* (1983), de la Peña (1988, 1996), Ridgely & Tudor (1994), do Rosário (1996), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Wetmore (1926).



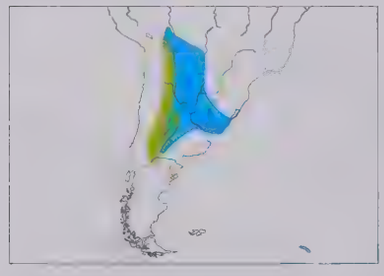
63. White-crested Tyrannulet

Serpophaga subcristata

French: Tyranneau à toupet **German**: Weißscheitel-Kleintyrann **Spanish**: Piojito Tiquitiqui

On following pages: 64. White-bellied Tyrannulet (*Serpophaga munda*); 65. Mouse-coloured Tyrannulet (*Phaeomyias murina*); 66. Cocos Flycatcher (*Nesotriccus ridgwayi*); 67. Yellow Tyrannulet (*Capsiempis flaveola*); 68. Sharp-tailed Tyrant (*Culicivora caudacuta*); 69. Bearded Tachuri (*Polystictus pectoralis*); 70. Grey-backed Tachuri (*Polystictus superciliaris*); 71. Dinelli's Doradito (*Pseudocolopteryx dinelliana*); 72. Crested Doradito (*Pseudocolopteryx sclateri*); 73. Subtropical Doradito (*Pseudocolopteryx acutipennis*); 74. Warbling Doradito (*Pseudocolopteryx flaviventris*); 75. Bronze-olive Pygmy-tyrant (*Pseudotriccus pelzelni*); 76. Hazel-fronted Pygmy-tyrant (*Pseudotriccus simplex*); 77. Rufous-headed Pygmy-tyrant (*Pseudotriccus ruficeps*).

Taxonomy. *Sylvia subcristata* Vieillot, 1817, Paraguay.
Taxonomic status controversial; sometimes considered conspecific with *S. munda*, but the two differ in plumage, also slightly in voice, and in Argentina are narrowly parapatric with limited hybridization; further study needed. Two subspecies recognized.
Subspecies and Distribution.
S. s. subcristata (Vieillot, 1817) - Bolivia (from N La Paz) and S Brazil (S from S Mato Grosso) S through Paraguay to Argentina (S to N Chubut).
S. s. straminea (Temminck, 1822) - SE Brazil (S Piauí and Bahia S to Rio Grande do Sul) and Uruguay.



Descriptive notes. 11 cm; 6-7 g. Has thin white supercilium from bill to just behind eye, white broken eyering, thin dusky eyeline; greyish-olive above, crown and nape more pure grey, a few blackish central crown feathers partially concealing white coronal stripe; wings dusky to blackish, two bold whitish to pale buffy wingbars, outer webs of most remiges broadly edged pale buffy; tail dusky, outer web of outer rectrices whitish; face greyish-white, chin and throat white, breast grey, belly and lower abdomen pale yellow; iris dark brown; bill thin, black; legs grey. Sexes alike. Juvenile has buffy wingbars, little or no white in crown. Race *straminea* has brighter yellow belly than nominate. Voice. Song, during which tail shaken vigorously, a soft, cheery, but almost mechanical-sounding trill with few introductory rising notes, "psee psee psee-e-e-e-e-e-e", this repeated every 3-4 seconds during dawn song; also slower, bubbly "tweetweetweetweetweetwee", and occasionally other, more jumbled chatters.
Habitat. Lowland tropical forest edge, deciduous woodland, gallery forest, tall scrub, *cerrado*, gardens and plantations, also fencelines in agricultural areas; sea-level to 2000 m in Brazil, to 700 m in Argentina.
Food and Feeding. Insects. Very active, parulid-like tyrannulet, pausing only briefly while flitting through outer edges of scrubby vegetation, frequently displaying crest. Prey taken by perch-gleaning, hover-gleaning, and sallying into air or against vegetation; hover-gleaning accounted for up to 90% of foraging strikes in one study.
Breeding. Aug-Dec in Brazil and Argentina. Nest built by both sexes, a neat, tightly constructed open cup, outside diameter 6 cm, inside diameter 3·5 cm, height 5·5 cm, made of plant fibres, lined with feathers and other soft material, and profusely decorated with lichen, placed 1-6 m up on horizontal branch or tucked in small bromeliads in shrubby tree. Clutch usually 2 eggs, occasionally 3; incubation and fledging periods not recorded.
Movements. Partial migrant, but migratory habits still uncertain; apparently present in E Bolivia only Apr-Sept, presumably non-breeding visitors from extreme S populations, but apparently present and breeding Sept-Feb just across border in W Mato Grosso. Resident throughout year extreme SE Brazil (Rio Grande do Sul) and Uruguay.
Status and Conservation. Not globally threatened. Fairly common to common. Occurs in numerous protected areas throughout its range, e.g. San Rafael and Ybycuí National Parks, both in Paraguay, Beni Biosphere Reserve and Noel Kempff Mercado National Park, both in Bolivia, Aparados da Serra, Caparaó, Itatiaia, Serra da Canastra and Tijuca National Parks, all in Brazil, and Costanera Sur Ecological Reserve and San Juan de Poriahú Private Reserve (in Iberá Provincial Reserve), both in Argentina. Exhibits tolerance of converted habitats within its relatively large range, and is not at any risk.
Bibliography. Babarskas *et al.* (2003), Belton (1985), Bó (1969), Brooks *et al.* (1993), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Cove & Vidal-Ojeda (2003), Cueto & López (2002), Di Giacomo (2004), Dubs (1992), Fitzpatrick (1980c), Harris (1998), Hayes (1995), Herzog (2001), Klimaitis & Moschione (1987), Lanyon (1988b), López (1997), Lowen *et al.* (1996), Meyer de Schauensee (1982), Narosky & Di Giacomo (1993), Narosky & Salvador (1998), Narosky & Yzurieta (1987, 1993), Nores *et al.* (1983), de la Peña (1988, 1995, 1997), Remsen & Traylor (1989), Ridgely & Tudor (1994), do Rosário (1996), Short (1975), Sick (1993, 1997), Smith (1971), Stotz *et al.* (1996), Straneck (1993), Traylor (1977), Urben-Filho *et al.* (2000), Wetmore (1926), Zimmer (1940b, 1955b).

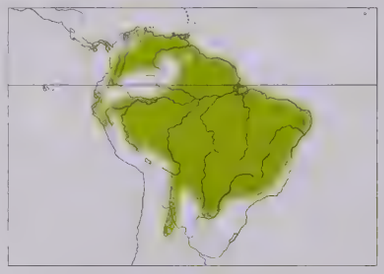
64. White-bellied Tyrannulet

Serpophaga munda

French: Tyranneau à ventre blanc **Spanish**: Piojito Ventriblanco
German: Weißbauch-Kleintyrann
Other common names: Grey-crowned Tyrannulet ("*S. griseiceps*")

Taxonomy. *Serpophaga munda* Berlepsch, 1893, Samaipata, Santa Cruz, Bolivia.
Taxonomic status controversial; sometimes considered a race of *S. subcristata*, but the two differ in plumage, also slightly in voice, and in Argentina are narrowly parapatric with limited hybridization; further study needed. Described taxon *S. griseiceps*, from Bolivia (Cochabamba), with reduced white in crown and more buffish wingbars, widely believed to be based on juvenile specimens of present species, and thus treated as synonym of it, but now considered by some to represent a separate species on grounds of voice, plumage and distribution; further research required. Monotypic.
Distribution. Breeds in Andes of W Bolivia (S from La Paz) and W Argentina (S to Neuquén and W Rio Negro); migrates E, as far as coast in SE Brazil and Uruguay, and as far N as NC Bolivia (S Beni).

Descriptive notes. 11·5 cm; 8 g. A grey-and-white version of *S. subcristata*. Has thin white supercilium from bill to just behind eye, white broken eyering, thin dusky eyeline; crown and nape pure grey, a few blackish central crown feathers partially concealing white coronal stripe, otherwise plain grey with only faint olive tinge above; wings dusky to blackish, two bold white wingbars, outer webs of most remiges broadly edged whitish to pale buff; tail dusky, outer webs of outer rectrices whitish; face greyish-white, chin and throat white, breast pale grey, belly and lower abdomen white, sometimes faintly tinged creamy yellow; iris dark brown; bill thin, black; legs grey. Sexes alike, female slightly smaller. Juvenile has buffy wingbars, little or no white in crown. Voice. Song, during which tail shaken vigorously, a soft, mechanical rattle beginning with a few introductory notes, "psee-psee-e-e-e-e-e-e-e-e-e-e-e", slightly higher-pitched, noticeably faster and longer than that of *S. subcristata*, repeated every 3 seconds during dawn song, and sometimes almost as frequently during daytime while patrolling territory; also slower, syncopated "tsi, tsu-tsu, tsu-tsu, tsu-tsu" and other, more jumbled chatters.
Habitat. Semi-arid montane scrub, thorn-forest, and deciduous woodland in foothills and highlands, to 2900 m; in non-breeding season, found in Chaco and variety of other scrub and open-country habitats, including agricultural areas.
Food and Feeding. Insects. Very active, parulid-like tyrannulet, pausing only briefly while flitting through outer edges of scrubby vegetation, frequently displaying crest. Prey taken by perch-gleaning and by sallying into air or against vegetation.
Breeding. Oct-Jan in Argentina. Nest built by both sexes, taking 4-7 days, a neat, tightly constructed open cup, outside diameter 5·5 cm, inside diameter 3·5 cm, height 5·5 cm, made of grass stems and other plant fibres, decorated with spider oothecae and lichens, profusely lined with feathers, once almost entirely tinamou (Tinamidae) feathers, and with plant wool; placed 3-5 m up on horizontal or tilted branch at junction of narrow limbs, usually enclosed by dense cover and thorny twigs, in shrubby tree, especially chañar (*Geoffroea*) or other thorny shrub. Clutch 2-3 eggs; incubation by both sexes (unusual among Tyrannidae), period 13-15 days; both parents feed chicks, nestling period 13-14 days.
Movements. Descends to lower elevations and moves N & E into Chaco and Patagonian lowlands during austral winter, some straying all the way to coastal regions of SE Brazil and Uruguay.
Status and Conservation. Not globally threatened. Fairly common to common; rare breeder in Paraguayan Chaco. Recorded at Beni Biosphere Reserve, in Bolivia.
Bibliography. Babarskas *et al.* (2003), Belton (1985), Bencke *et al.* (2002), Canevari *et al.* (1991), Chesser (1997), Cintra & Yamashita (1990), Cory & Hellmayr (1927), Di Giacomo (2004), Fjeldså & Krabbe (1990), Friedmann (1927), Herzog (2001), Joseph (1996), Lanyon (1988b), López (1997), Mezquida (2004), Mezquida & Marone (2000, 2002), Meyer de Schauensee (1982), Miserendino (1998), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nellar (1993), Nores *et al.* (1983), de la Peña (1987, 1988, 1995, 1997), Ridgely & Tudor (1994), Short (1975), Smith (1971), Stotz *et al.* (1996), Straneck (1993), Traylor (1977), Wetmore (1926), Zimmer, J.T. (1940b, 1955b), Zimmer, K.J. & Whittaker (2000).



Genus *PHAEOMYIAS* Berlepsch, 1902

65. Mouse-coloured Tyrannulet

Phaeomyias murina

French: Tyranneau souris **German**: Graubraun-Kleintyrann **Spanish**: Piojito Pardo
Other common names: Tumbes Tyrannulet (*tumbezana*, *inflava* and *maranonica*)

Taxonomy. *Platyrhynchus murinus* Spix, 1825, Joazeiro, Rio São Francisco, northern Bahia, Brazil.
Race *tumbezana* recently treated as a separate species, presumably including *inflava* and *maranonica*, but definitive studies lacking. Described taxon *ignobilis* (from SC Bolivia, NW Argentina and Paraguay) indistinguishable from nominate in large series, and thus merged with latter. Seven subspecies recognized.
Subspecies and Distribution.
P. m. eremonoma Wetmore, 1953 - Pacific lowlands of Panama.
P. m. incomta (Cabanis & Heine, 1859) - Colombia (N & Andes) and N Ecuador E to Venezuela (S to Apure, N Amazonas and N Bolívar) and Trinidad (including Monos I).
P. m. tumbezana (Taczanowski, 1877) - Pacific lowlands of SW Ecuador and NW Peru (Tumbes, E Piura, NE Lambayeque).
P. m. inflava Chapman, 1924 - arid NW Peru from C Piura and C Lambayeque S to N Lima.
P. m. maranonica J. T. Zimmer, 1941 - arid NC Peru in Marañón Valley, W Amazonas, E Cajamarca and E La Libertad.
P. m. wagae (Taczanowski, 1884) - the Guianas, Amazonian Brazil, E Peru and N Bolivia.
P. m. murina (Spix, 1825) - C, E & S Brazil (Maranhão, Ceará and Pernambuco S to Mato Grosso and São Paulo), C Bolivia (Cochabamba S to Tarija), Paraguay and NW Argentina (S to La Rioja).

Descriptive notes. 12 cm; 7-9 g. Nondescript brownish flycatcher with medium-sized bill. Nominate race has broad but weakly defined whitish to creamy supercilium, narrow whitish eyering; uniformly olive-brown to grey-brown above; wings dusky, wing-coverts tipped and inner remiges broadly edged whitish to dull cinnamon (wingbar colour variable, from bright cinnamon in fresh plumage to almost pure white in worn plumage); tail dusky; face and throat pale greyish-white to pure white, grading to pale yellow below, breast washed or flammulated with pale olive; iris brown; bill rather thick and rounded, horn-coloured, lower mandible pale pink at base; legs grey. Sexes alike. Juvenile resembles adult. Races vary mainly in brightness and intensity of cinnamon cast overall; *eremonoma* similar to nominate, with wing-coverts edged dull buff; *incomta* is very similar to nominate but browner above, paler and creamy white below, breast more greyish than olive; *wagae* has darkest green cast above, more intense yellow below, narrower extent of white on throat, somewhat larger bill; *inflava* has ochraceous wingbars and remex edges broad but diffuse, underparts dirty white, lacking yellow, with pale brownish-grey breast; *tumbezana* is not so pale as previous, has brighter cinnamon wingbars, darker grey-brown breast, pale yellow below limited to centre of belly; *maranonica* resembles previous, but slightly more richly coloured and yellower below. Voice. Dry, nasal chatter preceded by 1-2 sharper notes, "chéé-dit-tr-tr-tr-tr-tr-tr-tr-tr" or "jejejejejejew", often gives only the first 2 notes several times before the chatter; dawn song a lively series of chattery notes ending in sharper "tu-túp", repeated over and over, often increasing in intensity. On arid Pacific coast (*tumbezana*) a sharp, squeaky "squeeky-squeey-kit!".
Habitat. Arid lowland and lower montane scrub, cactus scrub and thorn-scrub, deciduous woodland, *cerrado*, river-edge forest, gallery forest, early second growth, early-successional brush along river margins, borders of humid forest, also parks, gardens, mangroves. Sea-level to 2400 m, mostly below 1000 m; in Bolivia breeds to 2150 m (one record at 3085 m), but only below 800 in austral winter.
Food and Feeding. Insects; fruits, especially of mistletoe (Loranthaceae), also eaten extensively. Usually forages alone, in dense foliage; perches upright, with short pauses between foraging attempts. Makes variety of sally-gleaning manoeuvres, especially upward hover-gleans and upward strikes.
Breeding. May-Oct in Colombia, Apr-Jun in Surinam and Oct-Dec in Argentina and Brazil. Nest, built by female alone, an open cup composed of plant fibres and mosses, with feathers incorporated

throughout and in lining, usually placed less than 4 m above ground in fork of branch or crotch of thin tree. Clutch 2 eggs, laid with interval of 1 day; incubation, by female alone, 14-17 days; chicks fed by both parents, with insects, berries added after 8-10 days, nestling period 17 days.
Movements. Moves downslope after breeding; S populations in Bolivia, S Brazil, Argentina and Paraguay migrate N, apparently spending austral winter in Amazon Basin.
Status and Conservation. Not globally threatened. Uncommon to common. Occurs in many national parks and other protected areas throughout its large range. Able to thrive in wide variety of dry and moist habitats; accepts secondary and converted habitats. Spreads into new areas, e.g. E lowlands in Ecuador, following deforestation. Not likely to be at any risk in the near future.

Genus *NESOTRICCUS* C. H. Townsend, 1895

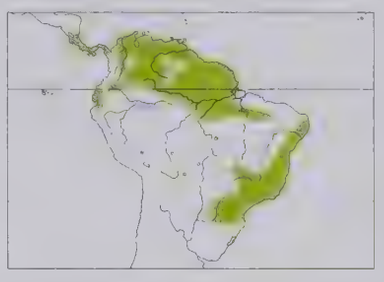
66. Cocos Flycatcher

Nesotriccus ridgwayi

French: Tyranneau de Cocos **German**: Cocos-Insel-Tyrann **Spanish**: Mosquerito del Coco
Other common names: Cocos Island Flycatcher

Taxonomy. *Nesotriccus Ridgwayi* C. H. Townsend, 1895, Cocos Island, off Pacific coast of Costa Rica. Affinities somewhat uncertain; anatomical and behavioural characters indicate that it is closely related to *Phaeomyias*. Monotypic.
Distribution. Cocos I, SW of Costa Rica.

Descriptive notes. 11 cm; 11 g. Variably coloured tyrannid with unusually long and broad bill. Above, is greyish-olive to dark brownish-olive, crown like back, faint supercilium slightly paler; wings and tail dusky, two wingbars and narrow edges of remiges dull yellowish-buff; greyish-buff to pale yellowish below, breast washed brownish to olive; iris dark brown; upper mandible brown to black, lower mandible whitish, flesh-coloured or pale horn with dusky tip; legs dark grey. Sexes alike. Juvenile is browner, with buffy to cinnamon wingbars. VOICE. Male has two song types, an explosive, dry, descending chatter of 6-9 syllables, speeding up near end, and a series of low-intensity "tic" notes followed by explosive trill of 7-10 syllables, both types loudest at onset, both sometimes interspersed with staccato notes; female has only one song, an explosive series of 9-10 notes followed by additional, much softer notes trailing off, song loudest at onset and descending slightly as it trails off; members of pair often sing rapidly back and forth in crude duet, typically initiated by female.
Habitat. Humid tropical and subtropical forest and forest edge, second growth, and scrubby and swampy areas, from sea-level to 575 m.
Food and Feeding. Arthopods; occasionally fruits. In analysis of 26 stomachs, diet overwhelmingly dominated by fulgoroid homopterans (planthoppers representing 43% and 64% of prey in two separate years), followed by orthopterans (6-12%) and ants (Hymenoptera; 7-14%), then arachnids (5%) and beetles (Coleoptera; 3-15%). Fruits taken include *Clusia rosea*; seeds regurgitated. Forages in dense vegetation, well above ground, making short pauses and frequent upward strikes against leaf undersides; also uses aerial hawking, hover-gleaning and perch-gleaning; evasive prey often pursued acrobatically after the initial sally.
Breeding. Jan-Apr. Nest constructed by both sexes, a substantial open cup, outside diameter 7·5 cm, inside 4·5 cm, of plant fibres, fine black fungal rhizomorphs (*Marasmius*), copiously lined with feathers, and generously adorned with spider oothecae, 10-25 m above ground and well anchored to twigs and vines within outer foliage near top of tall tree; territory size 0·25 ha. Clutch apparently only 1 egg; female alone incubates, period not recorded; fledging period not documented.
Movements. Resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in Cocos Island EBA. Common in most habitats. Estimated population of several tens of thousands, within global range of c. 25 km². Main threat is introduced predators, primarily rats (*Rattus*) and cats, and introduced herbivores (deer, pigs, goats), but no evidence so far of a decline in the species' range or population. Pigs, especially, devastate the lower strata and understorey of native forest and inhibit forest regeneration, but the flycatcher appears tolerant of at least some habitat disturbance. No efforts have been made to reduce populations of introduced mammals. Cocos I has no permanent settlements, although ecotourism is increasing to some degree, but it still retains a dense and largely undisturbed forest cover and was declared a national park in 1978.
Bibliography. Anon. (1998a), Collar *et al.* (1994), Cory & Hellmayr (1927), Eisenmann (1955), Kroodsma *et al.* (1987), Lanyon (1984b, 1988b), Ridgway (1907), Sherry (1985, 1986), Slud (1967), Stattersfield & Capper (2000), Stiles & Skutch (1989), Stotz *et al.* (1996), Traylor (1977).



Genus *CAPSIEMPIS* Cabanis & Heine, 1859

67. Yellow Tyrannulet

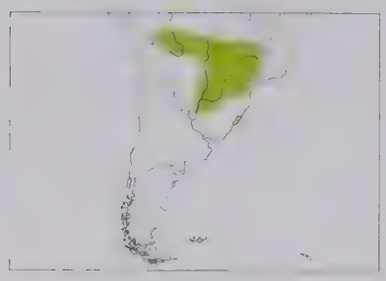
Capsiempis flaveola

French: Tyranneau flavéole **German**: Zitronentyrann **Spanish**: Mosquerito Amarillo

Taxonomy. *M[uscicapa] flaveola* M. H. K. Lichtenstein, 1823, Bahia, Brazil.
Genus was previously merged with *Phylloscartes*, but cranial and syringeal evidence suggest relationships elsewhere within Tyrannidae, perhaps near *Phaeomyias* and *Nesotriccus*; vocal similarities suggest relationship with *Inezia subflava-caudata* group. Proposed race *amazonus* (the Guianas, N & EC Brazil), described on basis of very few specimens, appears to be not reliably distinguishable from *cerula* in larger series of specimens; thus, merged with latter. Five subspecies recognized.
Subspecies and Distribution.
C. f. semiflava (Lawrence, 1865) - S Nicaragua S to E Panama, including Coiba I.
C. f. leucophrys Berlepsch, 1907 - NC Colombia (Sucre E to Magdalena Valley) and NW Venezuela (base of Sierra de Perijá S to Táchira and W Mérida, and SW Lara).
C. f. magnirostris Hartert, 1898 - SW Ecuador (Pichincha S to Guayas and El Oro).
C. f. cerula Wetmore, 1939 - locally E of Andes in Colombia, Venezuela, the Guianas, N Brazil (E Amazonas and R Branco E to Amapá), E Ecuador, SE Peru and N Bolivia.
C. f. flaveola (M. H. K. Lichtenstein, 1823) - E Bolivia (N Santa Cruz) E to E & SE Brazil (Pernambuco S to Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).

Descriptive notes. 11·5 cm; 8 g. Relatively long-billed tyrannid with upper mandible somewhat curved. Nominate race has prominent bright yellow supercilium, bright yellow broken eyering; dark yellowish-olive above, crown slightly darker and with feathers somewhat elongated to form bushy crest; wings and tail dusky olive, two broad but indistinct wingbars pale yellow to buffy yellow; throat yellow, face yellowish, underparts bright saturated yellow, breast tinged ochraceous, side of breast tinged olive; iris dark brown; bill black, lower mandible typically pale at base; legs dark grey. Sexes alike. Juvenile resembles adult. Races differ mainly in coloration and bill size, also wingbars generally more distinct in N: *semiflava* has much paler yellow underparts; *leucophrys* has pure white supraloral area and most of supercilium, whitish throat; *cerula* is larger and longer-billed than others except previous, from which it differs in having all-yellow supercilium; *magnirostris* has larger bill, pale yellow supercilium. VOICE. Extremely vocal, with variety of pleasant whistled or jumbled sputtery notes, mellow single or double whistles, excited variable mix of whistled notes, e.g. "pit-te-keek" or "wheet-eet, wheet-eet, whee" or "taytiréétì", repeated many times in succession, sometimes speeding up; often sung by both members of pair as duet. Also dry, nasal trill, "brrrrrrrt".
Habitat. Humid lowland habitats away from tall forest; dense thickets, vine tangles and bamboo stands, including those associated with large forest openings and edges of lakes and streams; also dense second growth, and low, dense, scrubby vegetation in overgrown pastures and coffee plantations; also mangroves. Found in thickets of gallery forest in Colombia and N Brazil; in shrubby vegetation on sandy soil in Surinam; apparently restricted to dense *Guadua* bamboo stands in SE Peru; dense forest edges and *restinga* in Brazil. To 1500 m, mostly lower.
Food and Feeding. Small insects; occasionally small fruits and berries. Almost always forages in pairs or in family groups of 3-4 individuals, rarely joins mixed-species flocks. Very active, restlessly moving about through thick vegetation, often difficult to see. Food obtained mostly by perch-gleaning; occasionally by sallying short distances (less than 1 m) to hover-glean prey from leaf surfaces, rarely in aerial sallies.
Breeding. Apparently in virtually all months in Costa Rica, and perhaps also in Panama (nest found in Sept); Apr-May in Colombia and Jul probably through Dec in E Peru; fledgling in Nov in Brazil. Nest (Costa Rica) a substantial open cup of light-coloured plant fibres, grass blades, bark shreds or moss, with moss or selaginella attached to outer wall, placed 3-6 m up in fork or crevice of low tree or tall, dense shrub. Clutch 2 eggs; incubation and fledging periods not documented.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to common. Occurs in many national parks and other protected areas throughout its extensive range, e.g. Río Negro Jaguar Reserve and Tarcol Lodge, in Costa Rica, Río Claro Reserve and Tinigua National Park, in Colombia, Machalilla National Park and Río Palenque Science Centre, in Ecuador, Pacaya-Samiria National Reserve, in Peru, Caaguazú, San Rafael and Ybycuí National Parks, all in Paraguay, and Iguaçu, Itatiaia, Serra da Canastra and Tapajós National Parks, all in Brazil. Given its tolerance of converted habitats and secondary habitats, this species is not considered likely to become threatened in near future.

(1955b), Zimmer, K.J. & Whittaker (2000).



Genus *CULICIVORA* Swainson, 1827

68. Sharp-tailed Tyrant

Culicivora caudacuta

French: Tyranneau à queue aiguë **German**: Spitzschwanz-Grastyrann **Spanish**: Tachurí Coludo
Other common names: Sharp-tailed Grass-tyrant

Taxonomy. *Muscicapa caudacuta* Vieillot, 1818, Paraguay.
Affinities uncertain, and genus often treated as *incertae sedis*, because of unusual plumage and tail feathers, presence of only ten rectrices, and non-exaspidean tarsi. Probably related to *Polystictus* on basis of similarities in plumage, bill morphology, behaviour and habitat. Monotypic.
Distribution. Locally in E Bolivia (Beni, La Paz, Santa Cruz), C & S Brazil (Mato Grosso, Mato Grosso do Sul, C Goiás, and S Bahia S to São Paulo and W Paraná), E Paraguay and N Argentina (S to Santa Fe, Entre Ríos and Corrientes).
Descriptive notes. 10·5 cm. Distinctively plumaged tyrannid with unique long, graduated tail. Male has blackish crown, slightly bushy, bordered below by broad white supercilium, narrow black eyeline,

rest of face warm buffy brown; upperparts buffy brown, broadly streaked blackish; wings buffy brown, feathers edged and streaked with black and pale buff; tail buffy brown, central rectrices stiffened, webs of most rectrices decomposed and stiffened (resembling *Synallaxis* spinetail) on distal end; chin white, underparts pale yellowish-white, flanks deeply suffused warm cinnamon buff; iris dark brown; bill black; legs black. Female is slightly smaller and shorter tailed than male, crown browner. Juvenile is more buffy overall. Voice. Song a series of weak, short, ascending burry whistles, "tweee tweee tweee", presumably by male, as sometimes initiates duet in which another individual (female?) up to 15 m away gives 4-5 rapid "chip" notes, rising and then falling, immediately after each whistle (reminiscent of *Todirostrum* duets); call a series of unmusical "tick" notes, sometimes in rapid series by juveniles after song of adult.

Habitat. *Campo* and dry grassland, wetter and taller portions of native grassland, especially where bordering shrubby marshes or streams, rarely in disturbed vegetation; mostly lowlands, to 1400 m.

Food and Feeding. Insects; possibly also seeds. Forages in pairs or in small, tight groups of up to five (sometimes to ten) individuals; occasionally joins mixed flocks of other grassland birds. Perches on vertical stems and shrubs, favours areas of taller exposed weeds and taller grass clumps; sallies to adjacent stems and leaves to pick, strike or hover-glean insects, makes occasional aerial sallies. Occasionally feeds by perching below mature seedheads, even hanging upside-down, and picking at them like a *Carduelis* finch or a tit (Paridae).

Breeding. Oct-Mar. Nest an elaborate open cup, external diameter 5 cm, internal diameter 3 cm, cup depth 4 cm, made of grasses, other plant fibres, thistle down and spiderwebs, placed low down in isolated shrub near ground; nests in N Argentina (Formosa) mostly in clumps of ironweed (*Vernonia chamaedrys*). Clutch 3 eggs; incubation and fledging periods not documented.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Mostly rare and very localized; locally fairly common; possibly most abundant and widespread in E Bolivia. Habitat loss probably the main factor behind its current rarity. By 1993, two-thirds of *cerrado* region in C Brazil had been heavily or moderately altered; most habitat conversion for eucalypt (*Eucalyptus*) and pine (*Pinus*) plantations, livestock farming, and large-scale cultivation of soybeans, rice and other exportable crops has occurred since 1950, encouraged by government land reform. Outside protected areas, few remaining undisturbed areas may soon be degraded by spreading fires and overgrazing, or may completely disappear through agricultural conversion. Moreover, breeding pairs apparently confined to dry grassland; abundance thus highest in protected areas, e.g. in Noel Kempff Mercado National Park and Beni Biosphere Reserve, in Bolivia, Mbaracayú Forest Nature Reserve, in Paraguay, and Brasília, Emas and Serra da Canastra National Parks, all in Brazil. If habitat conversion is not halted, the species' conservation status will probably have to be upgraded to that of Vulnerable. In Paraguay, for example, it appears locally extinct in Orient, where no records since 1932. On other hand, recent range expansions recorded in Bolivia (La Paz) and Argentina (Entre Ríos) and recently rediscovered in E Paraguay.

Bibliography. Bates & Parker (1998), Bates *et al.* (1998), Canevari *et al.* (1991), Capper *et al.* (2000), Cavalcanti (1988), Chebez (1994), Chesser (1997), Collar & Andrew (1988), Collar *et al.* (1994), Cory & Hellmayr (1927), Di Giacomo (1996, 2004), Dubs (1992), Fitzpatrick (1980c), Hayes (1995), Lowen *et al.* (1996), Madroño & Esquivel (1995), Narosky & Salvador (1998), Parker & Willis (1997), Parker, Castillo *et al.* (1991), Parker, Stotz & Fitzpatrick (1996), Pearman & Abadie (1995), de la Peña (1988), Ridgely & Tudor (1994), Short (1975), Sick (1993, 1997), Silveira (1998), Souza (1999), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993), Traylor (1977), Traylor & Fitzpatrick (1982), Willis & Oniki (1988c).

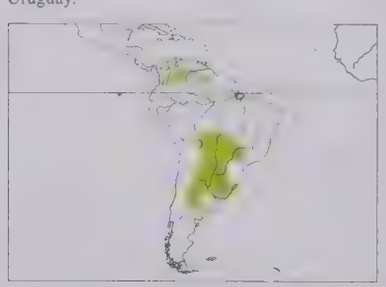
Genus *POLYSTICTUS* Reichenbach, 1850

69. Bearded Tachuri

Polystictus pectoralis

French: Tyranneau barbu **German**: Streifenkinn-Grastyrann **Spanish**: Tachurí Barbado

Taxonomy. *Sylvia pectoralis* Vieillot, 1817, Paraguay.



Was for long treated in a separate genus, *Habrura*; relationship with *P. superciliaris* needs confirmation. Race *bogotensis* (possibly extinct) probably merits rank of full species. Three subspecies recognized.

Subspecies and Distribution.

P. p. bogotensis (Chapman, 1915) - very local in temperate zone in Cundinimarca (savannas of Bogotá) and Valle (upper Dagua Valley), in Colombia.

P. p. brevipennis (Berlepsch & Hartert, 1902) - E Colombia, S Venezuela, Guyana, Surinam and N Brazil (Roraima, Amapá, W Pará).

P. p. pectoralis (Vieillot, 1817) - E Bolivia (Santa Cruz), S Brazil (locally from Mato Grosso S to Rio Grande do Sul), Paraguay, N Argentina (S to Mendoza, La Pampa and Buenos Aires) and Uruguay.

Descriptive notes. 8-10 cm; 6-8 g (*brevipennis*). Male nominate race has dusky grey to blackish crown, elongated feathers forming flattened bushy crest with semi-concealed white coronal patch; short white supercilium, narrow blackish eyeline; upperparts buffy brown, rump tawny to rufous; wings dusky, feathers edged cinnamon-buff, two bright cinnamon-buff wingbars; tail dusky; head side and chin ("beard") finely striped black and white, underparts pale yellowish-white, washed with cinnamon on breast and flanks; iris fuscous brown; bill black; legs black. Female is slightly smaller than male, duller, crown and face mostly brown, throat whitish, lacks "beard". Juvenile has reddish edges of primaries, buffy wingbars, deeper yellowish underparts. Race *brevipennis* is very similar to nominate but significantly smaller (male wing chord 40-43 mm, compared with 46-50 mm in nominate), crown feathers less elongated, male with less black on face and throat; *bogotensis* is distinctive, with much narrower, more elongated crown feathers, less white in crown, back more tawny, wingbars and edges of remiges deeper tawny, supercilium bright buff, side of head ochraceous tawny, flanks much deeper, richer tawny, only few black feathers on throat. Voice. Song a plaintive "wheee-whidididirrr" or "tee-tee-tee-teet", sometimes ending in low, guttural trill and followed by wing-buzz; weak rising "feee" or "pewee", with upward tail-flicking, as contact call.

Habitat. *Campo*, drier portions of native grassland, savanna with scattered shrubs, tall grass in *cerrado*; also low heath-like shrubs and tall grass in SE Venezuela (Gran Sabana); very rarely in disturbed vegetation. Mostly lowlands, to 1300 m; *bogotensis* at 2600-2700 m.

Food and Feeding. Insects. Inconspicuous; forages singly or in pairs, occasionally joins mixed flocks of other grassland birds. Perches on vertical stems; sallies to adjacent stems to glean prey, rarely flying far.

Breeding. Jun-Jul in E Colombia and Sept-Jan in Argentina and Brazil. Possibly polygynous; speculation that only female cares for young needs confirmation. Flight display for 20-100 m, angling upwards to 10 m above ground, while uttering weak song ending in orthopteran-like wing-buzzing; in near-dark before dawn, male flies in circles over grass while giving song and wing-buzz every 3 seconds. Nest an elaborate open cup, external diameter 5 cm, internal diameter 4 cm, cup depth 3 cm, made of grasses, other plant fibres, thistle down and spiderwebs, placed less than 1 m above ground in shrub or thistles, sometimes sewn to two or more stalks. Clutch 3 eggs; incubation and fledging periods not documented.

Movements. Apparently an austral migrant; records from Bolivia and adjacent Brazil only during winter months.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Usually rare to uncommon, but perhaps often overlooked; very local, but fairly common in a few localities. Fairly common in part of Meta (Colombia), in Roraima (N Brazil), and in one area in Córdoba (Argentina). Believed to be declining in Venezuela, and endangered in Paraguay; no recent records from Bolivia. Race *bogotensis* possibly extinct. Occurs in Canaíma National Park, in Venezuela, Sipaliwini Savanna Nature Reserve, in Surinam, Tatí Jupí Reserve, Mbaracayú Forest Nature Reserve, Sombrero Private Reserve and San Rafael National Park, all in Paraguay, and Otamendi Reserve, San Juan de Poriahú Private Reserve (in Iberá Provincial Reserve) and Mburucuyá National Park, all in Argentina; in Brazil, up to six individuals observed per day in Itirapina State Ecological Station, and found also in Das Emas and Chapada dos Guimarães National Parks. Current rarity probably a result mainly of habitat loss. By 1993, two-thirds of *cerrado* in C Brazil had been heavily or moderately altered; most habitat conversion for eucalypt (*Eucalyptus*) and pine (*Pinus*) plantations, livestock farming, and large-scale cultivation of soybeans, rice and other exportable crops has occurred since 1950, encouraged by government land-reform schemes; outside protected areas few undisturbed areas remain, and these may soon be degraded by spreading fires and overgrazing, or could completely disappear through agricultural conversion. Grasslands in Paraguay, Argentina and elsewhere face similar threats.

Bibliography. Babarskas *et al.* (2003), Brooks *et al.* (1993), Canevari *et al.* (1991), Capper *et al.* (2000), Chebez (1994), Chesser (1997), Collar & Andrew (1988), Collar & Wege (1995), Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), Di Giacomo (2004), Fjeldså & Krabbe (1990), Haverschmidt & Mees (1994), Hayes (1995), Hilty (1985, 2003), Hilty & Brown (1986), King (1978/79), Klimaitis & Moschione (1987), Lowen *et al.* (1996), Maceda *et al.* (1997), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Parker & Willis (1997), de la Peña (1988), Ridgely & Tudor (1994), Short (1975), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Traylor (1977), Willis & Oniki (1988c), Zimmer (1955b).

70. Grey-backed Tachuri

Polystictus superciliaris

French: Tyranneau bridé **German**: Graunacken-Grastyrann **Spanish**: Tachurí Gris

Taxonomy. *E[uscarthmus] superciliaris* Wied, 1831, Vale Fundo, southern Bahia, Brazil.

Affinities uncertain; relationship with *P. pectoralis* requires confirmation. Monotypic.

Distribution. Mountain ridges of interior SE Brazil from C Bahia S to N São Paulo.

Descriptive notes. 9·5 cm; 6 g. Has short white supercilium, white eyering; crown grey, feathers elongated and partially concealing white coronal patch; upperparts brownish-grey; wings dark dusky brown, tips of wing-coverts and edges of remiges faintly paler brown; tail dusky; chin whitish, throat and underparts medium pinkish-buff, fading to whitish on lower belly; iris dark brown; bill black; legs black. Sexes alike, female slightly smaller than male. Juvenile has cream-coloured belly. Voice. Rapid and repeated "pilrup-pilrup-pilrup" and "fruirilrilrilrilril"; weak, fast, musical trill beginning with stuttering notes, rising slightly, then trailing off; also "tee-kpuj" and quiet contact call, "purp".

Habitat. Rocky grassland with scattered shrubs (*campo rupestre*), abandoned brushy pastures, high-altitude grassland, and brushy edges of cloudforest; 900-2300 m, mostly below 1700 m.

Food and Feeding. Insects. Forages mainly alone, also in pairs or trios. Clings to vertical stems, or perches on low shrubs, rarely dropping to ground; mainly sally-gleaning and perch-gleaning, often returning to same perch; weak flier.

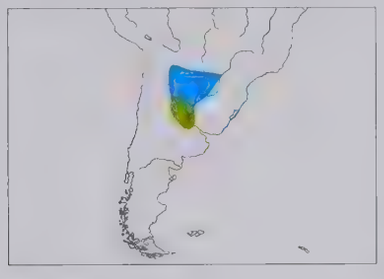
Breeding. Jul-Sept. Nest a small cup of rootlets and moss, placed in fork of small shrub. Clutch 1-2 eggs; no information on incubation and fledging periods.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Central Brazilian Hills and Tablelands EBA and Atlantic Forest Mountain EBA. Generally uncommon and very local; perhaps commonest in Serra do Espinhaço. In Caraça National Park, the species is common in *campo rupestre* and abandoned pastures and, especially, in natural grassland; it occurs also in Serra da Canastra and Serra do Cipó National Parks. Montane habitats within its range have suffered less destruction than have adjacent lowland areas; increasing habitat conversion for timber and charcoal extraction, cattle-ranching and associated fires are principal current threats, although the species persists in partially degraded habitats such as abandoned mines.

Bibliography. Canevari *et al.* (1991), Collar & Andrew (1988), Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), Ferreira de Vasconcelos (1999), Ferreira de Vasconcelos & Lombardi (1996), Ferreira de Vasconcelos & Melo-Júnior (2001), Ferreira de Vasconcelos, Maldonado-Coelho & Buzzetti (2003), Ferreira de Vasconcelos, Maldonado-Coelho & Durães (1999), Hellmayr (1906a, 1906b), Meyer de Schauensee (1982), Parker *et al.* (1996),

de la Peña & Rumboll (1998), Ridgely & Tudor (1994), Sick (1993, 1997), da Silva (1995), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993), Traylor (1977), Willis & Oniki (1991), Zimmer (1955b).



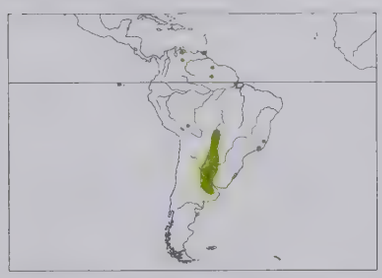
Genus *PSEUDOCOLOPTERYX* Lillo, 1905

71. Dinelli's Doradito

Pseudocolopteryx dinelliana

French: Doradite de Dinelli **German**: Dinellisumpftyrann **Spanish**: Doradito Tucumano
Other common names: Rufous-edged Pygmy-tyrant

Taxonomy. *Pseudocolopteryx dinellianus* Lillo, 1905, Tucumán, Argentina.
Possibly forms a superspecies with *P. acutipennis*. Monotypic.
Distribution. Very locally in N Argentina (NE Córdoba, Santiago del Estero, Tucumán); S Bolivia, Paraguay and SW Brazil (Mato Grosso do Sul) in non-breeding season.



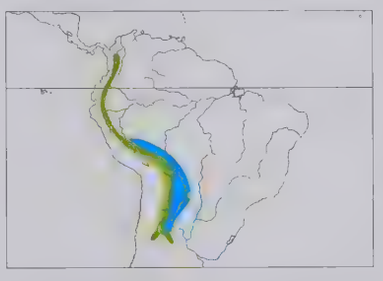
Descriptive notes. 11 cm. Plumage is yellowish-olive above, head with rufescent tinge on crown, lores and cheeks; wings more grey, wing-coverts and remiges narrowly edged with buff, modified primaries P6 and P7 narrow and lanceolate; entirely bright yellow below; iris dark brown; bill slender, parulid-like, black; legs blackish-grey. Differs from very similar *P. flaviventris* mainly in less brown upperparts, more rufescent lores and cheeks. Female is slightly duller than male. Juvenile undescribed. VOICE. Soft but twangy "redek-redek-redidek", or "zeik-zeik".
Habitat. Reedbeds, grassy marsh vegetation, and adjacent shrubs; to 500 m.
Food and Feeding. Little known. Forages deep inside marsh vegetation, perch-gleaning insects and spiders.
Breeding. Sept-Apr. Presumably has aerial display (suggested by presence of modified primaries), but not yet documented. Nest a deep cup constructed of vegetable fibres and spider oothecae, lined with feathers, attached to marsh vegetation or in fork of low shrub within marsh. Clutch 3 eggs; incubation and fledging periods not recorded.
Movements. Migratory; moves to extreme S Bolivia and W Paraguay during austral winter (Apr-Aug).
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Not well known; apparently rare to locally common. More or less common in its major stronghold in Bañados del Río Dulce and Laguna de Mar Chiquita Natural Park; occurs also in the unprotected Bañados de Figueroa (Santiago del Estero) and Bañado La Estrella (Formosa). No recent records from Tucumán. Canalization and other modifications may adversely affect its wetland habitats, and savanna-type habitat probably under pressure from agricultural expansion. Nevertheless, extensive areas of suitable habitat remain in both its breeding and its non-breeding ranges (e.g. Estancia San Antonio Private Nature Reserve and Tacuara National Park, both in Paraguay), and population seems relatively stable.
Bibliography. Bornschein (2000), Brooks *et al.* (1993), Canevari *et al.* (1991), Chesser (1997), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1927), David & Gosselin (2002b), Di Giacomo (2004), Dinelli (1933), Hayes (1995), Joseph (1996), Laubman (1934), Lowen *et al.* (1996), Meyer de Schauensee (1982), Molli (1985), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores & Yzurieta (1980, 1991), Nores *et al.* (1983), Olrog (1979a), de la Peña (1988, 1997), de la Peña & Rumboll (1998), Ridgely & Tudor (1994), Short (1975), Stattersfield & Capper (2000), Stotz *et al.* (1996), Traylor (1977), Wege & Long (1995).

72. Crested Doradito

Pseudocolopteryx sclateri

French: Doradite de Sclater **German**: Schopfsumpftyrann **Spanish**: Doradito Copetón

Taxonomy. *Anaeretes sclateri* Oustalet, 1892, Chile; error = Buenos Aires, Argentina.
Isolated N populations described as race *striaticeps* on basis of pale lower mandible, but this evidently a trait of immature. Monotypic.
Distribution. Isolated populations in Venezuela, Trinidad and Guyana; also N Bolivia, S & SE Brazil, Paraguay and E Argentina.



Descriptive notes. 11 cm; 7-8 g. Pronounced shaggy crest unique within genus. Male has entire upperparts, including crown, pale olive, elongated crown feathers blackish with yellowish-white edges, semi-concealed yellow crownstripe, subtle dusky streaks on back; cheeks dusky; wings pale olive, two wingbars and edges of tertials dull whitish, modified primaries P6 and P7 with incised and attenuated vanes; chin and entire underparts bright yellow; iris dark brown; bill thin, narrow, parulid-like, black; legs black, hallux nail unusualy long and sharp. Female is duller yellow, black crest more broadly edged pale yellow (less contrast with crown), rest of head paler, slight supercilium very pale yellow, primaries normal, lower mandible pinkish-orange. Juvenile resembles female, but shorter crest has more ochre, less black, underparts very pale. VOICE. Song of S populations composed of sharp introductory bill-snaps ("tsik") followed by 3 gentle, high-pitched, squeaky notes with a bill-snap interspersed, "tsik, tsik, tsik, tsee-tsik-tsee-lee"; in N, song reported as "tsik-tsik-tsee-lee", the "tsik" most likely also bill-snaps; call note a high, thin, soft "sik".
Habitat. Reeds, marshes, and tall thin grass near water; to c. 500 m.
Food and Feeding. Insects and spiders. Often seen in pairs or in small family groups of up to four individuals. Moves among vegetation by clinging to sides of sedge or reed stems; occasionally emerges briefly and perches high over reeds to view surroundings more broadly. Feeds by perch-gleaning in marshy vegetation, sedges (Cyperaceae), low growth at borders of lagoons, and tall weeds, especially *Polygonum* and water hyacinth (*Eichhornia*).
Breeding. Sept-Jan in S; adults with begging juveniles in Jun in N. Nest in S a deep cup made of grass, little lining but profusely filled with coccoons and spider oothecae, attached to vertical stems over water, in SE Brazil (Rio Grande do Sul) 35 cm over water; in Trinidad similar nest but without oothecae; a pair observed during final stages of building in Paraguay, only female seen to collect and weave material, followed closely by male throughout process, nest a thin hemispherical cup, final dimensions 7·5-9 cm high (lowest on entrance side), 3·5-5·5 cm deep, outside diameter 6·1 cm, inside diameter 2·4 cm, made of fine wiry brown rootlets of dried aquatic plant (c. 80% of mass), coarse, dry sedge stems and grass panicles up to 80 mm long and 1·5 mm across, dry weight 2·25 g, outer surface and especially rim covered profusely with sulphur-yellow and whitish spider oothecae and ochraceous lepidopteran coccoons, no well-differentiated lining except for few macerated grass blades and flattened oothecae, rim woven tightly around vertical stems in clump of sedge along wall of taller reedbed, concealed from one side, suspended over water. Male produces loud wing "whirr", most likely with incised primaries. Clutch 2 eggs in S; incubation and fledging periods not documented.
Movements. Resident. In past, was thought to be an austral migrant.
Status and Conservation. Not globally threatened. Not well known; apparently very local, but sometimes quite common. Found to be fairly common in Aug at PVR estancia near Beni Biosphere Reserve, in Bolivia; in Argentina, a fairly common breeder in San Juan de Poriahú Private Reserve (in Iberá Provincial Reserve), in Corrientes, and two areas near Laguna de Mar Chiquita, in NE Córdoba.
Bibliography. Babarskas *et al.* (2003), Bostwick & Zyskowski (2001), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Di Giacomo (1992, 2004), Dubs (1992), ffrench (1991), Hayes (1995), Herklots (1961), Hilty (1999, 2003), Klimaitis & Moschione (1987), Lowen *et al.* (1996), Meyer de Schauensee (1982), Narosky & Di Giacomo (1993), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (1983), de la Peña (1987, 1988, 1997), de la Peña & Rumboll (1998), Ridgely & Tudor (1994), do Rosário (1996), Short (1975), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Temple (2002), Traylor (1977), Wetmore (1926).

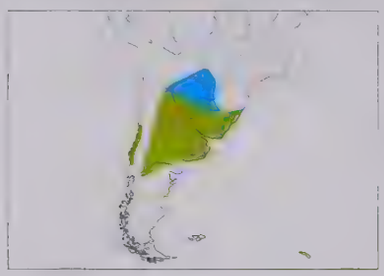
73. Subtropical Doradito

Pseudocolopteryx acutipennis

French: Doradite à ailes pointues **Spanish**: Doradito Oliváceo
German: Olivgrüner Sumpftyrann

Taxonomy. *Hapalocercus acutipennis* P. L. Sclater and Salvin, 1873, "Peruvia alta", Bogotá trade skin, Colombia.
Possibly forms a superspecies with *P. dinelliana*. Individuals from S part of range appear to be larger than those in N; further study needed. Monotypic.
Distribution. Very locally in Andes from Colombia (C & E cordilleras) S to NW Argentina; also lowlands in W Paraguay, and scattered records from lowlands of SE Peru and NE & E Bolivia.

Descriptive notes. 11 cm; 7-8 g. Male is uniformly bright olive-green above, with elongated crown feathers forming short, shaggy crest; wings olive-brown, feathers lightly edged with grey, in some specimens median and greater wing-coverts tipped dull cinnamon (two wingbars), modified primaries P6 and P7 incised and attenuated; tail bright olive-green; bright golden-yellow below; iris dark brown; bill slender, parulid-like, black; legs dark grey. Distinguished from *P. flaviventris* by brighter olive upperparts, brighter yellow underparts, no rufescent tone on crown. Female lacks incised outer primaries. Immature has pale base of lower mandible, more prominent buffy wingbars. VOICE. A series of buzzy, irregularly produced introductory notes followed by short nasal snort, "tzit-tzit-tzit t-konk"; call note while foraging "tzit".
Habitat. Reedbeds, marshes, moist sedge (Cyperaceae) pastures, and brush near water on hills and mountains in subtropical zones of Andes; less frequently in fields and tall grassy areas. In breeding season, at 2200-3550 m; not recorded above 700 m outside breeding season.
Food and Feeding. Insects. Forages singly or in family groups, usually remaining low and quiet under cover, occasionally perching atop grassy vegetation. Perch-gleans and hover-gleans from tips of grass.
Breeding. Dec-Apr in Bolivian highlands. Wing "whirr" during brief flight display, most likely produced by incised primaries. Deep cup-nest made of grass or other vegetable fibre, lined with feathers, placed among marsh vegetation. Clutch 3 eggs; incubation and fledging periods not recorded.
Movements. Many populations appear to be migratory. Birds from Argentina and Bolivia move N along Andes and to adjoining Amazonian lowlands and Paraguayan Chaco; strictly a non-breeding visitor (May-Aug) in Bolivian and Peruvian lowlands.
Status and Conservation. Not globally threatened. Rare in N part of range, red-listed in Colombia ("vulnerable") and Ecuador ("near-threatened"); fairly common farther S, e.g. in Argentina (Salta and Tucumán). Rarity in N most likely due to drainage and intensive grazing. Occurs in Tambopata-Candamo Reserved Zone, in Peru; has been recorded once in La Florida Park, near Bogotá, in Colombia.
Bibliography. Allen (1995), Bostwick & Zyskowski (2001), Cadena (2002a), Canevari *et al.* (1991), Chapman (1921), Chesser (1997), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Flores & Capriles (1998), Greenfield (2002), Hayes (1995), Hilty & Brown (1986), Lanyon (1988b), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Navas (2002), Nores *et al.* (1983), Parker (1982), de la Peña (1988), de la Peña & Rumboll (1998), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Short (1975), Stotz *et al.* (1996), Zimmer (1930, 1940b).



74. Warbling Doradito

Pseudocolopteryx flaviventris

French: Doradite babillarde **German**: Braunrücken-Sumpftyrann **Spanish**: Doradito Común

Taxonomy. *A[lecturus] flaviventris* d'Orbigny and Lafresnaye, 1837, Corrientes, Argentina.
Chilean birds may be slightly larger in size than those elsewhere in range; further study needed. Monotypic.

Distribution. Breeds C Chile (Santiago S to Valdivia), N & E Argentina (S to Chubut and Buenos Aires), Uruguay and SE Brazil (Rio Grande do Sul); in non-breeding season N to Paraguay.

Descriptive notes. 11 cm; 8 g. Male is dull olive-brown above, crown rufescent, lores and cheeks dusky; wings like back, wing-coverts and flight-feathers narrowly tipped and edged buffy; tail dusky olive-brown; entirely bright yellow below, brightest on throat; iris medium brown; bill very slender, black; legs dark grey. Female is like male, but base of lower mandible pale flesh-coloured. Juvenile is duller throughout, edges of wing feathers buffy, underparts bright buffy, somewhat greyer on throat and creamy yellow on belly. VOICE. A series of gentle and somewhat disjointed-sounding, high-pitched, staccato and squeaky notes, mechanical introduction followed by set of 4-8 more musical notes, "chek, chek, chek, chek-chick-chick-chiquetik" or "tk tk tk tk tk quít tuk péét tk-tuk, tk-quít", head snapping sharply upwards with each double note; "tek" call while foraging.

Habitat. Reedbeds, freshwater marshes, sawgrass (*Cortaderia*) marshes, and surrounding riparian vegetation; also cornfields and weed patches during migration. Sea-level to 500 m.

Food and Feeding. Insects. Forages alone or in pairs or family groups, mostly deep inside marsh vegetation; shy and inconspicuous. Mainly perch-gleans, occasionally makes short sallies into open air.

Breeding. Sept-Jan. Nest a loosely woven cup of fine straw or rush fibres attached to vertical marsh vegetation. Clutch 2-4 eggs; no information on incubation and fledging periods.

Movements. Populations breeding in extreme S migrate into N part of range in austral winter; Chilean birds apparently cross Andes to spend non-breeding season in Argentina. Vagrants recorded in Paraguay and Bolivia.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common; generally commoner in Argentina than in Chile.

Bibliography. Aguirre (1997), Araya & Chester (1993), Babarskas *et al.* (2003), Belton (1985), Bostwick & Zyskowski (2001), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Di Giacomo (2004), Fjeldså & Krabbe (1990), García & Vilina (1994), Gore & Gepp (1978), Harris (1998), Hayes (1995), Jaramillo (2003), Johnson (1967), Joseph (1996), Klimaitis & Moschione (1987), López (1997), Lowen *et al.* (1996), Meyer de Schauensee (1982), Narosky & Di Giacomo (1993), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Navas & Bó (2001), Nores *et al.* (1983), de la Peña (1987, 1988), de la Peña & Rumboll (1998), Ridgely & Tudor (1994), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Udvardy (1963), Weske (1972), Wetmore (1926).

Genus *PSEUDOTRICCUS*

Taczanowski & Berlepsch, 1885

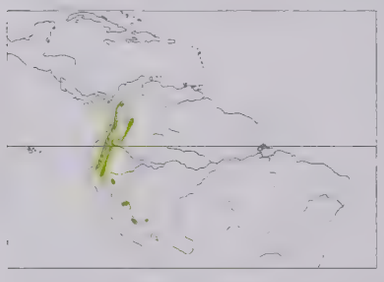
75. **Bronze-olive Pygmy-tyrant**

Pseudotriccus pelzelni

French: Tyranneau bronzé **German**: Bronzeolivtyrann **Spanish**: Tiranuelo Bronceado

Taxonomy. *Pseudotriccus pelzelni* Taczanowski and Berlepsch, 1885, Machay and Hacienda Mapoto, Tungurahua, Ecuador.

Forms a superspecies with *P. simplex*, and possibly conspecific. Races *berlepschi* and *annectens* intergrade on WC Colombian slopes. Four subspecies recognized.



Subspecies and Distribution.

P. p. berlepschi Nelson, 1913 - E Panama and NW Colombia (E to W Caldas).

P. p. annectens (Salvadori & Festa, 1899) - SW Colombia and NW Ecuador.

P. p. pelzelni Taczanowski & Berlepsch, 1885 - E Andes of Colombia and E Ecuador.

P. p. peruvianus Bond, 1947 - locally in E Andes of Peru (San Martín S to Cuzco).

Descriptive notes. 11-11·5 cm; 9-11 g. Tiny, dark pygmy-tyrant of subtropical forest undergrowth. Nominate race is entirely dark brownish-olive above, crown slightly darker than back, longer and broader crown feathers forming bushy crest (rarely raised); wings as back, wing-coverts and inner remiges diffusely edged warmer brown; tail as back; chin and throat creamy whitish, breast and flanks olive, belly and undertail-coverts creamy yellow; iris dark red to reddish-brown; bill black; legs grey. Sexes alike. Juvenile undescribed. Race *berlepschi* is darker and more brown above, crown blacker, wing-coverts more conspicuously edged rufous-brown, underparts paler yellow, bill larger; *annectens* is like previous, but back more bronze than dark brownish, crown greener, auriculars and neck brownish with bronzy cast, brighter yellow underparts, yellower cast to olive flanks; *peruvianus* resembles nominate but more green, less brownish, wing-coverts lack brownish edges. VOICE. Not very vocal; makes 4-6 short, wheezy "piff" notes c. 1 second apart, song a thin high-pitched trill; snaps bill repeatedly when alarmed.

Habitat. Humid montane forest, cloudforest; 300-2500 m.

Food and Feeding. Insects. Forages alone or in pairs, just above ground in dense forest undergrowth, perching on both vertical and horizontal twigs; flies with short bursts from perch to perch (audible whirring wing noise with each flight). Prey captured with short upward strikes; bill snapped audibly as bird strikes leaf and prey.

Breeding. Birds with enlarged gonads in May in Colombia. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common to common; often overlooked unless mist-netted. Fairly common on Cerro Pirre and Cerro Tacarcuna (both in Darién), in Panama; occurs also in Tambito Nature Reserve, in Colombia, and Manta Real (designated for protected status), near Guayaquil, in Ecuador. Probably locally extinct in areas where deforestation has been intense, e.g. in Colombian Andes.

Bibliography. Angehr *et al.* (2004), Anon. (1998a), Chapman (1917c), Cory & Hellmayr (1927), Cracraft (1985), Delgado (1985), Eisenmann (1955), Freile & Chaves (2004), Hilty (1997), Hilty & Brown (1986), Lanyon (1988a, 1988b), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Salaman (1994), Stotz *et al.* (1996), Strewe (2000b), Terborgh (1971), Traylor (1977), Traylor & Fitzpatrick (1982), Williams & Tobias (1994).

76. **Hazel-fronted Pygmy-tyrant**

Pseudotriccus simplex

French: Tyranneau à front brun **German**: Roststirntyrann **Spanish**: Tiranuelo Simple

Taxonomy. *Caenotriccus simplex* Berlepsch, 1901, Sandillani, La Paz, Bolivia.

Forms a superspecies with *P. pelzelni*, and possibly conspecific. Monotypic.

Distribution. SE Peru (Madre de Dios, Puno) and NW Bolivia (La Paz, Cochabamba).

Descriptive notes. 11-11·5 cm; 9-11 g. Tiny, dark pygmy-tyrant with bronzy forecrown, of subtropical forest undergrowth. Has forecrown, lores, eyering and side of head strongly tinged dull rufous; otherwise entirely dark brownish-olive above, crown slightly darker than back, longer and broader crown feathers forming bushy crest (rarely raised); wings as back, wing-coverts and inner remiges diffusely edged warmer brown to rufous; tail as back; chin and throat creamy whitish, breast and flanks olive, belly and undertail-coverts creamy yellow; iris dark red to reddish-brown; bill black; legs grey. Sexes alike. Juvenile has less rufous on forecrown, is brighter yellow below. VOICE. Not very vocal; makes several wheezy "piff" notes c. 1 second apart, song a thin high-pitched trill; snaps bill repeatedly when alarmed.

Habitat. Humid montane forest, dense cloudforest; 1100-2100 m.

Food and Feeding. Arthopods. In stomach contents from SE Peru 29 prey items identified, including homopteran bugs (planthoppers, 29%), coleopterans (21%), hymenopterans (wasps 14%, ants 17%), arthropod eggs (10%), other arthropods (9%). Forages alone or in pairs, just above ground in dense forest undergrowth, perching on both vertical and horizontal twigs; flies with short bursts from perch to perch (audible whirring wing noise with each flight). Prey captured with short upward strikes; bill snapped audibly as bird strikes leaf and prey.

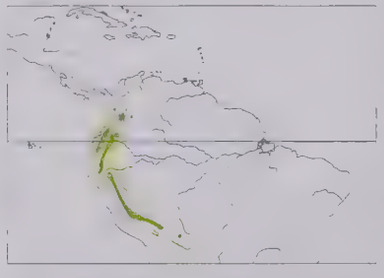
Breeding. Birds with gonads enlarged in Aug-Sept in Peru. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species; present in Bolivian and Peruvian Lower Yungas EBA. Uncommon; not well known. Occurs in Madidi National Park, in Bolivia. Forests in lower Yungas of Peru and Bolivia have been extensively converted for agriculture, especially cultivation of cash crops such as coca and coffee; several large protected areas have, however, been established, including Tambopata-Candamo Reserved Zone, in Peru.

Bibliography. Begazo (1995), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Hennessey & Gómez (2003), Hennessey, Herzog & Sagot (2003), Lanyon (1988a, 1988b), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1977), Zimmer (1940a).

77. **Rufous-headed Pygmy-tyrant**



Pseudotriccus ruficeps

French: Tyranneau à tête rousse **German**: Rotkopftyrann **Spanish**: Tiranuelo Cabecirrojo

Taxonomy. *Musicapa* [*sic*] *ruficeps* Lafresnaye, 1843, "Bogota", Colombia.

Formerly placed in a monotypic genus, *Caenotriccus*. Monotypic.

Distribution. Colombia (locally in C & E Andes, also W slope in N & S) S to Ecuador (S to Cotopaxi) on W slope and to Bolivia (La Paz, Cochabamba) on E slope.

Descriptive notes. 11 cm; 7-9 g. Distinctive chestnut-headed pygmy-tyrant. Has entire head and throat bright orange-rufous; upperparts dark olive; wings dark dusky, all feathers broadly edged dull chestnut, giving fully chestnut-winged appearance (browner C Peru); tail dull chestnut; breast and flanks greyish-olive, centre of belly and undertail-coverts creamy yellow; iris dark brown; upper mandible black, lower mandible mostly yellowish; legs grey. Sexes alike. Juvenile is mostly dark olive, wings rufous-brown, chin whitish, head brownish-olive; head acquires rufous feathers of adult gradually, beginning with forehead. VOICE. Loud, explosive buzzy trill lasting several seconds, "tzzzzzzzzzzzzeuw", sometimes ending with a snap; song a bright, more protracted, higher-pitched version, first descending and then ascending; often snaps bill repeatedly.

Habitat. Humid montane forest, dense cloudforest, vine thickets, and forest borders; mainly 1850-3350 m, down to 400 m in SW Colombia (Nariño).

Food and Feeding. Insects. Forages alone or in groups of 2-4 individuals, usually near ground in dense forest undergrowth, perching on both vertical and horizontal twigs, sometimes landing briefly on ground; flies with short bursts from perch to perch. Prey captured with short, explosive upward strikes; bill snapped audibly as bird strikes leaf and prey.

Breeding. Fledglings in Jun in Colombia and Jul-Mar in E Peru. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to common; rare in Bolivia. Fairly common in Serranías Cofán (Sucumbíos), in Ecuador; occurs also in Tambito Nature Reserve, in Colombia, Podocarpus National Park and Guandera Biological Reserve, in Ecuador, and Machu Picchu Historical Sanctuary, in Peru. Probably locally extinct in areas where deforestation has been intense, e.g. in SW Ecuador.

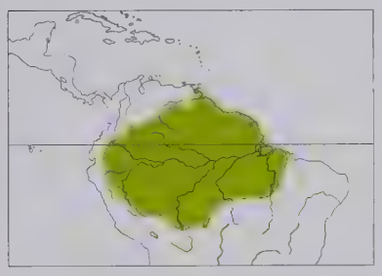
Bibliography. Allen (1998), Baez *et al.* (1997), Chapman (1917c, 1921), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Hennessey, Herzog & Sagot (2003), Hilty & Brown (1986), Lanyon (1988a, 1988b), Meyer de Schauensee (1982), Remsen (1985), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996), Terborgh (1971), Traylor (1977), Traylor & Fitzpatrick (1982), Walker (2001), Williams & Tobias (1994), Zimmer (1940a).

PLATE 21 ➤

PLATE 21

inches 2

cm 5



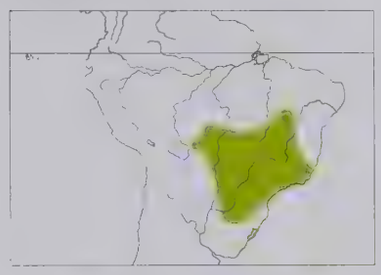
Genus *CORYTHOPIS* Sundevall, 1836

78. **Ringed Antpipit**

Corythopis torquatus

French: Corythopis à collier **Spanish**: Mosquero Terrestre Norteño
German: Nördlicher Brustbandtyrann

Taxonomy. *Corythopis torquata* Tschudi, 1844, Chanchamayo Valley, Junín, Peru.
Genus was for long placed in the family Formicariidae or together with the gnateaters (*Conopophaga*) in the Conopophagidae; numerous anatomical, behavioural and genetic characters, however, indicate affinities within present family, probably closest to *Pseudotriccus*. This species forms a superspecies with *C. delalandi*; the two are possibly conspecific, but differ vocally, also slightly in plumage, and ranges apparently overlap in C Brazil (upper R Xingu drainage). Races intergrade broadly, and individual variation pronounced; proposed race *subtorquatus* described from two specimens (one of each sex) from Amazon region of N Bolivia, but indistinguishable from nominate in scrutiny of larger series of specimens from same region and adjacent SE Peru. Three subspecies recognized.
Subspecies and Distribution.
C. t. sarayacuensis Chubb, 1918 - Amazon Basin in SE Colombia, E Ecuador and NE Peru.
C. t. anthoides (Pucheran, 1855) - Amazon and S Orinoco Basins in S Venezuela, the Guianas and Brazil (E to N Maranhão, S to N Goiás, N Mato Grosso and Rondônia).
C. t. torquatus Tschudi, 1844 - Amazon Basin in EC & SE Peru, W Brazil and N Bolivia.



Descriptive notes. 13·5-14 cm; 15-18 g. Distinctive, ground-walking tyrannid of the forest floor. Nominate race has rather dull greyish-brown crown, faint whitish loral and postocular spots; upperparts, including wings and tail, dark brownish-olive; face pale greyish-olive, chin and throat white; underparts white, flanks suffused greyish-olive, bold broad black streaks beginning in almost solid necklace on upper breast and extending most heavily down flanks, unmarked on belly and undertail-coverts; wing-linings dark greyish; iris medium brown, grey-brown or grey; upper mandible blackish, lower mandible pale flesh-coloured with yellow to pinkish-orange near base; legs very long, pale grey to pinkish-grey. Sexes similar, female smaller than male. Juvenile has fewer, paler and more brownish breast streaks. Races *sarayacuensis* is on average smaller than nominate, crown colour same as back; *anthoides* is also smaller, crown slate-grey. Voice. Most commonly a deliberately delivered, descending, clear 2-note whistle, "peeew prayeur", second note rising and then falling below pitch of first, sometimes in series of more than two; often snaps bill during foraging, and especially when startled.
Habitat. Humid tropical evergreen forest, both *terra firme* and seasonally flooded forest or swamp-forest, less commonly in mid-successional river-margin forest. Sea-level to 1400 m, mostly below 500 m. Less often in second growth than *C. delalandi*.
Food and Feeding. Arthropods; occasionally lizards and frogs. Of 61 prey items found in analysis of stomach contents from SE Peru, beetles (Coleoptera) formed 40%, hymenopterans 27% (ants 20%, wasps 7%), homopteran bugs 8%, lepidopteran larvae 8%, arachnids 5%, frogs 3%, other 9%. Forages alone. Walks with steady gait, one foot ahead of other, along dark forest floor, peering mainly upwards, occasionally springing up to strike at prey on leaf undersides 10-20 cm overhead, with loud bill-snap at each attempt.
Breeding. Birds in breeding condition in Apr-May in S Venezuela, Nov-Dec in E Amazonian Brazil and Aug-Dec in SE Peru. Nest a large, moss-covered, oven-shaped dome 12 cm high, 13 cm long, side entrance 5·5 cm across, nest-chamber made with fine plant fibres and rhizomorphs, 9·5 cm deep, built atop base of leaf detritus on forest floor. Clutch 2 eggs; incubation period not documented; nestling period 13 days; one member of pair often calling nearby while other enters nest.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Occurs in many national parks and other protected areas throughout its reasonably large range. Much of this species' habitat remains in relatively pristine condition, and it is not considered likely to become threatened in near future.
Bibliography. Allen (1995), Ames (1971), Ames *et al.* (1968), Bates & Parker (1998), Begazo (1995), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Fitzpatrick (1980c, 1981, 1985b), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Kirwan & Sharpe (1999), Meyer de Schauensee (1982), Oniki & Willis (1980, 1983b), Oren & Parker (1997), Peres & Whittaker (1991), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977), Traylor & Fitzpatrick (1982), Willard *et al.* (1991).

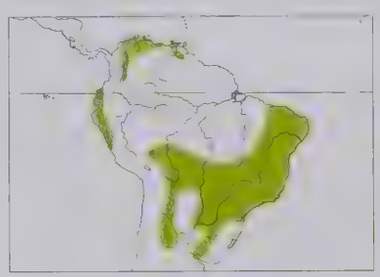
79. **Southern Antpipit**

Corythopis delalandi

French: Corythopis de Delalande **Spanish**: Mosquero Terrestre Sureño
German: Südlicher Brustbandtyrann
Other common names: Delalande's Antpipit

Taxonomy. *Muscicapa delalandi* Lesson, 1830, Rio de Janeiro, Brazil.
Genus was for long placed in the family Formicariidae or together with the gnateaters (*Conopophaga*) in the Conopophagidae; numerous anatomical, behavioural and genetic characters, however, indicate affinities within present family, probably closest to *Pseudotriccus*. This species forms a superspecies with *C. torquatus*; the two are possibly conspecific, but differ vocally, also slightly in plumage, and ranges apparently overlap in C Brazil (upper R Xingu drainage). Monotypic.
Distribution. E Bolivia (E Santa Cruz), S Brazil (S Mato Grosso, S Goiás, S Maranhão, Minas Gerais and Espírito Santo S to NW Rio Grande do Sul), E Paraguay and NE Argentina (Misiones, NE Corrientes).

Descriptive notes. 13·5-14 cm, 14-18 g. Distinctive, ground-walking tyrannid of the forest floor. Has olive upperparts, crown slightly greyer, faint whitish loral and postocular spots; wings and tail same colour as back; face pale greyish-olive, chin and throat creamy white; underparts white, flanks suffused greyish-olive, bold broad black streaks beginning in almost solid necklace on upper breast and extending most heavily down flanks, unmarked on belly and undertail-coverts; wing-linings white; iris medium to dark brown; upper mandible blackish, lower mandible pale flesh-coloured with yellow to pinkish-orange near base, mouth-lining yellow-orange; legs very long, pale greyish-flesh. Differs from *C. torquatus* in being paler and less olive above, chin and throat more creamy, wing-linings white (not dark greyish). Sexes alike. Juvenile resembles adult. Voice. Most commonly a deliberately delivered, descending, clear 6-note whistle, "peee prayeur, pi-pi-peepit?"; often snaps bill during random foraging, and especially when startled.
Habitat. Humid tropical lowland forest and secondary woodland; sea-level to 1000 m, mainly below 800 m. Found more frequently in second growth and small forest patches than *C. torquatus*.
Food and Feeding. Arthropods; occasionally lizards and frogs. One stomach contained six beetles (of family Tenebrionidae). Forages alone; does not accompany mixed-species flocks. Walks with steady gait, one foot ahead of other, along dark forest floor, peering mainly upwards, occasionally springing up to strike at prey on leaf undersides 10-20 cm overhead, with loud bill-snap at each attempt.
Breeding. Birds in breeding condition in Nov in Bolivia and Oct-Dec in Argentina. Nest a well-camouflaged oven-shaped dome, 8·4 cm high, 15·6 cm long, entrance hole 3·7 × 3·2 cm, on forest floor; three distinct layers, with base an unorganized heap of dried leaf detritus 0·5-2 cm deep, interior chamber 7·6 cm high woven of fine plant fibres (especially from small palm *Euterpes edulis*) 1-2·5 cm thick, and irregular outer covering 0·5- 1·5 cm thick mainly of live green moss with added leaves and dried material. Clutch 2-3 eggs, laid every other day; incubation period not recorded; chicks fed by both adults, fledge after 14 days, remain with parents for at least a further 18 days.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common. Occurs in several protected areas, including Caaguazú, San Rafael, San Luis and Ybycuí National Parks, all in Paraguay, and Brasília, Iguaçu and Serra da Canastra National Parks and Mata dos Godoy State Park (Paraná), all in Brazil. Rather tolerant of disturbed habitats, and found even in small and seriously degraded forest fragments.
Bibliography. Ames (1971), Ames *et al.* (1968), Belton (1985), Brooks *et al.* (1993), Canevari *et al.* (1991), Cory & Hellmayr (1927), Darrieu (1987), Hayes (1995), Lanyon (1988b), Lowen *et al.* (1996), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Olrog (1979a), de la Peña (1988), Ridgely & Tudor (1994), do Rosário (1996), Saibene *et al.* (1996), Sick (1993, 1997), Simon & Pacheco (1996), Stotz *et al.* (1996), Traylor (1977).



Genus *EUSCARTHMUS* Wied, 1831

80. **Tawny-crowned Pygmy-tyrant**

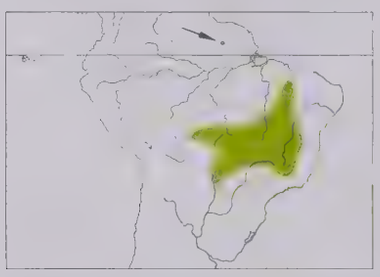
Euscarthmus meloryphus

French: Tyranneau à huppe fauve **Spanish**: Tiranuelo Copetón
German: Graubrust-Zwergtyrann

Taxonomy. *E[uscarthmus] meloryphus* Wied, 1831, Vale Fundo, southern Bahia, Brazil.
Genus once placed in the family Formicariidae because of odd tarsal scutellation; affinities within present family uncertain. Three subspecies recognized.
Subspecies and Distribution.
E. m. paulus (Bangs, 1899) - NE Colombia and N Venezuela (E to Sucre, S to NE Bolívar).
E. m. fulviceps P. L. Sclater, 1871 - W & SE Ecuador (S from Manabí, including coastal islands, also S Zamora-Chinchipe) and W & N Peru (Tumbes S to Lima, also arid Marañón Valley in Cajamarca, Amazonas and La Libertad).
E. m. meloryphus Wied, 1831 - E Brazil (Maranhão and Ceará S to Mato Grosso and Rio Grande do Sul), E Peru (E Puno), E Bolivia (S from Pando), N & E Paraguay, NW & NE Argentina (S to Tucumán and, in E, to Córdoba and N Buenos Aires) and Uruguay.

Descriptive notes. 10-10·5 cm; 7 g. Tiny, peculiar pygmy-tyrant with bushy bright rufous crown. Nominate race has lores and indistinct eyering dull buffy to whitish; drab brownish above, crown feathers slightly elongated around a large rufous coronal patch (semi-concealed); wings plain dusky brown, wing-coverts tipped rufous, edges of remiges indistinctly rufous; tail dusky; face buffy brown, throat and breast greyish-white, side of breast and flanks tinged brownish, rest of underparts creamy yellow; iris medium brown to chestnut; upper mandible black, lower mandible greyish or flesh-coloured; legs dark grey. Female is slight-

On following pages: 81. Rufous-sided Pygmy-tyrant (*Euscarthmus rufomarginatus*); 82. Grey-and-white Tyrannulet (*Pseudelaenia leucospodia*); 83. Lesser Wagtail-tyrant (*Stigmatura napensis*); 84. Greater Wagtail-tyrant (*Stigmatura budytoides*); 85. Paltry Tyrannulet (*Zimmerius vilissimus*); 86. Venezuelan Tyrannulet (*Zimmerius improbus*); 87. Bolivian Tyrannulet (*Zimmerius bolivianus*); 88. Red-billed Tyrannulet (*Zimmerius cinereicapilla*); 89. Mishana Tyrannulet (*Zimmerius villarejoi*); 90. Slender-footed Tyrannulet (*Zimmerius gracilipes*); 91. Golden-faced Tyrannulet (*Zimmerius chrysops*); 92. Peruvian Tyrannulet (*Zimmerius viridiflavus*).



ly smaller than male. Juvenile resembles adult. Race *paulus* has head side tinged fulvous to buffy, tail on average shorter; *fulviceps* has conspicuous bright buffy face and forecrown tinged rufescent, crown patch smaller, two prominent buffy wingbars. Voice. Distinctively noisy; dry, unmusical "plee-plit-irick" endlessly repeated, sometimes with several introductory "plee" notes before the staccato portion; often sings through heat of day from deep inside dense shrubs, reminiscent of cicada (Cicadidae) or locust (Locustidae).
Habitat. Arid lowland and montane scrub, overgrazed pastures with scattered dense bushes, dry weedy fields and waste areas, shrubby thickets, and dry forest edge. Sea-level to 2100 m where habitat permits, mostly below 1500 m; colonizes tropical zones following deforestation.
Food and Feeding. Insects. Forages alone, very near ground in densest shrubs; often extremely difficult to see. Moves actively from perch to perch, making short upward strikes and hover-gleans.
Breeding. Feb-May (after rainy season) in W Ecuador and Oct-Dec in Argentina. Weak open cup-nest of dead grass and plant stems, outside diameter 5·5 cm, height 4 cm, cup depth 3 cm, slung between thin twigs and plant stems in thick shrub, so thin that contents visible from outside. Clutch 2 eggs, laid with interval of 1day; incubation period 14-15 days; nestling period 11-12 days; adults frequently call from near or in nest.
Movements. Mainly resident; populations in extreme S appear to be present only during breeding season, suggesting some migration to N.
Status and Conservation. Not globally threatened. Fairly common to common. Occurs in many protected areas, including at least a dozen national parks and similar reserves, throughout its large range. Thrives in secondary and converted habitats; benefits from forest clearance, successfully colonizes resultant scrub habitat.
Bibliography. Babarskas *et al.* (2003), Belton (1985), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Darrieu (1987), Di Giacomo (2004), Dubs (1992), Euler (1900), Hayes (1995), Hilty (2003), Hilty & Brown (1986), Hudson (1920), Lanyon (1988b), Lowen *et al.* (1996), Marchant (1960), Narosky & Salvador (1998), de la Peña (1987, 1988, 1996), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgway (1907), do Rosário (1996), Short (1975), Sick (1993, 1997), Stotz *et al.* (1996), Wetmore (1926), Williams & Tobias (1994), Zimmer (1940b, 1955b).

81. **Rufous-sided Pygmy-tyrant**

Euscarthmus rufomarginatus

French: Tyranneau à flancs roux **Spanish**: Tiranuelo Flanquirrufo
German: Weißkehl-Zwergtyrann
Other common names: Rufous-edged Pygmy-tyrant

Taxonomy. *Hapalocercus rufomarginatus* Pelzeln, 1868, Calção de Couro and Rio das Pedras, São Paulo, Brazil.
Genus once placed in the family Formicariidae because of odd tarsal scutellation; affinities within present family uncertain. Proposed race *savannophilus* (Surinam) considered inseparable from other populations. Monotypic.
Distribution. Very locally in S Surinam (Sipaliwini), E & C Brazil (Amapá, and from E Maranhão and S Piauí S to S Mato Grosso, Mato Grosso do Sul, N São Paulo and Minas Gerais, and E to C Bahia), extreme NE Bolivia (Serranía de Huanchaca) and extreme NE Paraguay (Zanja Morotí, in Concepción).

Descriptive notes. 11 cm; 6 g. Has short whitish supercilium, thin eyering; uniform brown above, semi-concealed crown patch cinnamon-rufous; wings darker brown, wing-coverts tipped ochraceous (two distinct wingbars), inner remiges narrowly edged ochraceous; tail long, dusky, edged ochraceous; face light brown, throat white, underparts pale yellow, side of breast and flanks deeply warm ochraceous buff; iris dark brown; upper mandible black, lower mandible flesh-coloured; legs dark grey. Sexes alike. Juvenile undescribed. Voice. Distinctive, unmusical "tic" notes followed by a buzz, "tic, tic, tic, tiker-trrrrrk", also a longer series of buzzes ending with emphatic note, "trrrrrika", in response to playback; sings from tops of low shrubs and small trees, both members of pair may sing in antiphonal duet. Buzzy trills also as alarm.
Habitat. Restricted to pristine *campo* and *campo-cerrado*, and tall shrubby grassland; possibly also in bamboo-dominated scrub as a refuge after fire. Up to 1000 m.
Food and Feeding. Arthropods; also regularly small fruits. Forages in pairs, within a few centimetres of ground in grass and low shrubs, occasionally down to ground, but usually perching on grass stalks and low shrubs; often jerks tail upwards like a wren (Troglodytidae). Makes short sallies to glean arthropods.
Breeding. Not documented.
Movements. Resident.
Status and Conservation. VULNERABLE. Rare and local; more common at a couple of localities. Species was probably once widespread within its large range of c. 2,000,000 km², but now irregularly recorded at a few scattered areas. Isolated N population in the 1000-km² Sipaliwini Savanna Nature Reserve, in S Surinam, where fairly common, and one recent record from EMBRAPA Experimental Station, in N Brazil (Amapá). In N Bolivia substantial population remains in Serranía de Huanchaca, within Noel Kempff Mercado National Park, where extensive areas (c. 3000-5000 km²) of *campo* and *cerrado* are probably largest tracts of pristine habitat remaining, and 4 pairs/0·3 km² suggest that this population may number thousands; also common E of Riberalta, in Beni, but in only one of several grassland patches, and was fairly common along the Riberalta-Guayamirim road, in Santa Cruz. In C Brazil, recent records from sites in Mato Grosso, Mato Grosso do Sul, Bahia, Distrito Federal and Minas Gerais. Habitat loss probably the principal reason for its current rarity. By 1993, two-thirds of *cerrado* region in C Brazil had been heavily or moderately altered, with most conversion for eucalypt (*Eucalyptus*) and pine (*Pinus*) plantations, livestock farming, and large-scale cultivation of soybeans, rice and other exportable crops having occurred since 1950, encouraged by government land-reform measures; was presumed extinct in São Paulo (no records since 1821) until rediscovered in 1993 in Itirapina State Ecological Station. Away from protected areas there are few undisturbed areas left, and these could soon be degraded by spreading fires and overgrazing, or be lost entirely through agricultural conversion. Recent surveys in Brazil have revealed very few additional populations, e.g. in Brasília, Chapada Diamantina, Chapada dos Veadeiros and Chapada dos Guimarães National Parks, Mangabeiras Park (one record in 1989, none more recently), Serra das Araras Ecological Station, Chapada do Catuni (Minas Gerais), and at a site 170 km W of Correntina (Bahia); the species is, however, often absent in apparently suitable habitat, e.g. in Das Emas and Serra da Canastra National Parks, suggesting that there are other, as yet unknown reasons for its rarity.
Bibliography. Bates & Parker (1998), Bates, Parker *et al.* (1992), Bates, Stotz & Schulenberg (1998), Cavalcanti (1999), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1927), Cracraft (1985), Dubs (1992), Haffer (1974), Haverschmidt & Mees (1994), Hayes (1995), Mees (1968), Meyer de Schauensee (1982), Neto & Ramos (2001), Parker & Willis (1997), Ridgely & Tudor (1994), Sick (1993, 1997), da Silva *et al.* (1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Teixeira *et al.* (1991), Wege & Long (1995), Willis & Oniki (1988c, 1990).

Genus *PSEUDELAENIA* W. E. Lanyon, 1988

82. **Grey-and-white Tyrannulet**

Pseudelaenia leucospodia

French: Tyranneau gris et blanc **German**: Weißkronentyrann **Spanish**: Mosquerito Blanquigrís
Other common names: Ash-coloured Tyrannulet

Taxonomy. *Elaenia leucospodia* Taczanowski, 1877, Tumbes, Peru.
Genus hypothesized to be very close to *Stigmatura* on basis of numerous cranial and syringeal characters. Species was previously placed variously in *Elaenia*, *Myiopagis* and *Phaeomyias*. Birds from SW Ecuador sometimes separated as race *cinereifrons*, but considered probably indistinguishable from others. Monotypic.
Distribution. Arid Pacific slope and coast of W Ecuador (I de la Plata, off Manabí, also Puna I and W Guayas, S Loja) and NW Peru (S to La Libertad).

Descriptive notes. 12·5 cm; 10-11 g. Has white supraloral line; uniform pale greyish-brown above, large white coronal patch (semi-concealed), surrounding crown feathers slightly elongated and often parted into bifurcated crest; wings dusky, wing-coverts and flight-feathers narrowly edged whitish; tail grey; face greyish-white, entire underparts whitish, tinged grey on flanks and creamy on belly; iris dark brown; bill brownish-black, lower mandible broadly flesh-coloured at base, mouth-lining pink; legs grey. Sexes similar. Juvenile has less white in crown. Voice. Simple, short "chevit" or "chevit-chit".
Habitat. Arid scrub, brushy riparian thickets, dry arroyos and streambeds; sea-level to 800 m, mostly below 500 m.
Food and Feeding. Insects. Forages singly or in pairs, near tops of shrubs. Actively moves about with horizontal posture, tail often cocked above horizontal; perch-gleans and hover-gleans from vegetation; occasionally wags tail slowly.
Breeding. Feb-Apr, after rainy season; often two broods. Nest a beautifully neat, deep, barrel-shaped cup felted all over with soft plant down, no additional lining, supporting twigs sometimes exposed at base of cup, placed 2-7 m above ground on smooth branch (or where smaller twig inserts into large one) near centre of thick shrubby tree; nest sometimes reused for second brood, same nest tree used over several years. Clutch usually 3 eggs, occasionally 2; incubation period 16 days; nestling period 15-17 days.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tumbesian Region EBA. Uncommon to locally fairly common or common. In Ecuador, abundant on I de la Plata (off Manabí) and fairly common on Santa Elena Peninsula (Guayas). Occurs in Northwest Peru Biosphere Reserve, in Peru. Arid habitats within Tumbesian region are adversely affected by cattle grazing and agriculture in valley bottoms, but in general remain in reasonable condition.

Genus *STIGMATURA* P. L. Sclater & Salvin, 1866

83. **Lesser Wagtail-tyrant**

Stigmatura napensis

French: Calandrite du Napo **Spanish**: Rabicano Menor
German: Nördlicher Stelzentachurityrann

Taxonomy. *Stigmatura budytoides napensis* Chapman, 1926, junction of rivers Curaray and Napo, Peru.
Genus was formerly placed in the family Formicariidae because of its general resemblance to *Formicivora*. Forms a superspecies with *S. budytoides*. Two subspecies recognized.
Subspecies and Distribution.
S. n. napensis Chapman, 1926 - along larger rivers of C Amazonian and SW Orinoco drainages in extreme SE Colombia (near Leticia), SW Venezuela (along R Orinoco), E Ecuador, NE Peru and NC Brazil (E to R Tapajós).
S. n. bahiae Chapman, 1926 - NE Brazil (Pernambuco, NC Bahia).
Descriptive notes. 13 cm; 9·1-10·5 g. Distinctive tyrannid of Amazonian river islands. Nominate race has narrow pale yellow supercilium from bill to behind eye, indistinct pale yellow eyering, blackish eyeline; greyish-olive above, wings dusky, median and greater wing-coverts broadly white (forming broad longitudinal wing patch), edges of innermost remiges broadly white; tail long, dusky, slightly graduated, outermost three feather pairs with broad white oval shape at tips, outer rectrices with white outer web and broad yellowish-white basal band, latter usually extending to tail base; face pale yellowish, throat and entire underparts medium yellow, slight olive to greyish-

olive tinge across breast; iris dark brown; bill long, black; legs black. Distinguished from extremely similar *S. budytoides* mainly by slightly smaller size, usually white on tail base, no dark postocular patch. Sexes similar, female slightly smaller than male. Juvenile not described. Race *bahiae* has brownish upperparts, somewhat buffy underparts. VOICE. Soft, whistled "wheeert?" or "weeeéé" and harsh, descending rattle; partners often engage in animated, syncopated duet, one member singing "pfew skew" as other sings a more rattling "du' u'u", both flipping wings and tail upwards and forwards with each call.

Habitat. Early-successional vegetation, especially newly forming beaches with thick *Tessaria* and tall grasses, on islands along large rivers; also arid scrub in NE Brazil. To 300 m, occasionally to 500 m.

Food and Feeding. Insects. Forages in pairs or family groups. Moves actively, with short pauses; tail usually held cocked above horizontal, constantly fanned (exposing broad white tips and yellowish base) and pumped up over back, while wings slightly drooped. Perch-gleans and makes sallies to hover-glean from leaves, twigs and bark in shrubs.

Breeding. Not documented.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common. In Ecuador, apparently common on R Napo upstream to La Selva Lodge and on lower R Aguarico (below Lagartacocha).

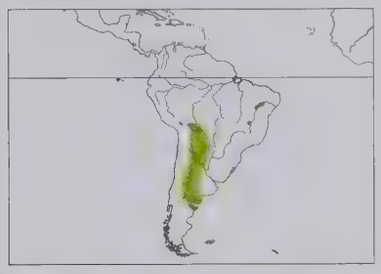
Bibliography. Cory & Hellmayr (1927), Hilty (1999, 2003), Hilty & Brown (1986), Lanyon (1988b), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgway (1907), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Zimmer (1940b).

84. **Greater Wagtail-tyrant**

Stigmatura budytoides

French: Calandrite bergeronnette **Spanish**: Rabicano Mayor
German: Südlicher Stelzentachurityrann

Taxonomy. *C[ulicivora] budytoides* d'Orbigny and Lafresnaye, 1837, Valle Grande, Santa Cruz, Bolivia. Genus was formerly placed in the family Formicariidae because of its general resemblance to *Formicivora*. Forms a superspecies with *S. napensis*. Four subspecies recognized.



Subspecies and Distribution.

S. b. budytoides (d'Orbigny & Lafresnaye, 1837) - NC Bolivia (Cochabamba, W Santa Cruz, N Chuquisaca).

S. b. inzonata Wetmore & J. L. Peters, 1923 - SE Bolivia, W Paraguay and NW Argentina (Jujuy E to Chaco, S to Córdoba and San Luis).

S. b. flavocinerea (Burmeister, 1861) - C Argentina (Mendoza, Córdoba and Buenos Aires S to Chubut).

S. b. gracilis J. T. Zimmer, 1955 - E Brazil (Pernambuco, N Bahia, possibly S Piauí; recently recorded in Minas Gerais).

Descriptive notes. 14·5-16 cm; 8·5-13·2 g (highland populations significantly larger). Distinctive tyrannid with long, graduated tail broadly tipped white. Nominate race has broad bright yellow supercilium from bill to well behind eye, blackish eyeline; greyish-olive above, wings dusky, median and greater wing-coverts broadly white (forming broad longitudinal wing patch), edges of innermost remiges broadly white, outer three primaries slightly narrowed; tail very long, dusky, slightly graduated, outer 3-4 pairs of rectrices with broad white oval at tips, outer web and broad basal band of outer rectrices white, base of tail blackish; face yellowish, auriculars dusky, throat and entire underparts bright yellow, slight buffy tinge across breast; iris dark brown; bill long, black; legs black. Sexes similar, female slightly smaller than male. Juvenile undescribed. Races vary in size (nominate largest) and in coloration and pattern: *inzonata* is paler yellow below with barely discernible buffy wash on breast, basal white band on rectrices smaller (but highly variable); *flavocinerea* has even paler yellow underparts, is more greyish (less olive) above, wing edgings greyer and less conspicuous, supercilium more whitish, rectrices with smaller apical spots and no white basal tailband; *gracilis* is significantly smaller than all other races, plumage resembles nominate. VOICE. Abrupt "churt", sometimes in series, varied occasionally into more complex chatter; partners often engage in distinctive, syncopated, animated duet, singing "whidididiteh" or "tri-ti-treeowhit" over and over, flipping wings and tail upwards and forwards with each call, and swivelling body.

Habitat. Arid scrub, deciduous woodland, Chaco woodland, and dry gallery forest; mainly sea-level to 1000 m, but to 2700 m in arid regions of Bolivian Andes.

Food and Feeding. Insects. Forages in pairs or family groups, from near ground to tops and outer foliage of tall shrubs, in open to dense vegetation, occasionally to ground or atop logs. Moves actively, with short pauses; tail usually held cocked above horizontal, constantly fanned (exposing broad white tips) and pumped up over back, while wings slightly drooped. Perch-gleans and makes sallies to hover-glean from leaves, twigs and bark. Gives audible wing-whir display while foraging in pairs.

Breeding. Oct-Dec in Argentina. Nest an open cup made of plant fibres and rootlets, bonded with spiderwebs, placed 1-2 m above ground on horizontal branch within dense shrub or small tree; favours thorny shrubs such as acacia (*Acacia*) and chañar (*Geoffroea*) where available. Clutch 2 eggs, laid with interval of 1 day; incubation 14-15 days; fledging 12 days.

Movements. S populations in Argentina believed to migrate to N portion of range during austral winter, but extent and geographical pattern of movements not clear.

Status and Conservation. Not globally threatened. Fairly common to common. Recent range extension S in E Brazil; race *gracilis* recorded in Minas Gerais (left bank of R São Francisco), where apparently rather common. No current risks identified.

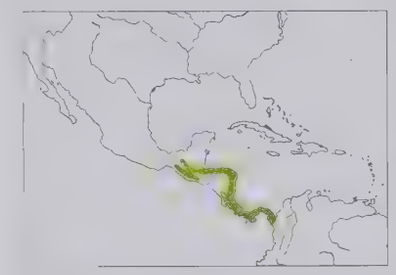
Bibliography. Canevari *et al.* (1991), Cory & Hellmayr (1927), Fjeldså & Krabbe (1990), Flores & Capriles (1998), Hayes (1995), Kirwan *et al.* (2004), Lanyon (1988b), Meyer de Schauensee (1982), Mezquida (2002), Miserendino (1998), Narosky & Di Giacomo (1993), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Navas & Bó (2001), Nores *et al.* (1983), Ordano (1998b), de la Peña (1987, 1988, 1997), Ridgely & Tudor (1994), Ridgway (1907), Schmitt *et al.* (1997), Schönwetter & Meise (1968), Short (1975), Sick (1993, 1997), Smith (1971), Stotz *et al.* (1996), Traylor (1977), Traylor & Fitzpatrick (1982), Wetmore (1926), Zimmer (1955b).

Genus *ZIMMERIUS* Traylor, 1977

85. **Paltry Tyrannulet**

Zimmerius vilissimus

French: Tyranneau gobemoucheron **Spanish**: Mosquerito Centroamericano
German: Weißstreif-Kleintyrann
Other common names: Mistletoe Tyrannulet



Taxonomy. *Elainia vilissima* P. L. Sclater and Salvin, 1859, Cobán, Guatemala.

Despite superficial resemblance to *Phyllomyias*, genus appears to be more closely related to *Phylloscartes*. Previously considered conspecific with *Z. improbus*, but differs in plumage, voice and habitat. Race *parvus* possibly a separate species; further study required. Two subspecies recognized.

Subspecies and Distribution.

Z. v. vilissimus (P. L. Sclater & Salvin, 1859) - S Mexico (Chiapas), S Guatemala and W El Salvador; also numerous sight records from Belize.

Z. v. parvus (Lawrence, 1862) - Honduras and E Nicaragua S to Panama and extreme NW Colombia (NW Chocó).

Descriptive notes. 10 cm. Small, short-tailed tyrannulet. Nominate race has broad white supercilia meeting above bill; crown dark brownish-grey, upperparts bright olive; wings dusky, wing-coverts, inner remiges and proximal parts of outer remiges edged bright yellow ("wedge" of dark remiges separating inner secondaries and primaries); tail dusky olive; throat and lower face whitish, auriculars olive; breast pearly grey, flammulated with darker grey or brownish, flanks and undertail-coverts yellow-green, heavily flammulated with olive, belly white; iris dull yellow to pale sandy brown; bill small and rounded, black; legs black. Sexes similar, female significantly smaller than male. Juvenile has dark brown eyes, less contrast between crown and back. Race *parvus* is significantly smaller than nominate, but remarkably variable in size (smaller in lowland Honduras and Nicaragua than in highlands of Costa Rica and Panama), has paler, greyish crown, narrower white supercilia, yellower edgings on wing feathers, only faint flammulations on breast and flanks. VOICE. Persistent series of whistled "pee-areet" or "pyeu" notes uttered at intervals of several to many seconds.

Habitat. Humid montane forest, forest borders, tall second growth with clearings, and shrubby pastures with scattered trees. Recorded from near sea-level to 2600 m; nominate race mainly 500-2600 m but descends from higher elevations in winter; *parvus* mainly below 500 m in Honduras and Nicaragua, to 2600 m in Costa Rica and Panama.

Food and Feeding. Insects; mistletoe (Loranthaceae) and other small berries regularly eaten. Forages singly or in pairs, often following mixed-species flocks in forest mid-storey and canopy. Actively hops and flits about in outer foliage, perching with horizontal posture, tail often cocked slightly above horizontal; perch-gleans and sally-gleans.

Breeding. Feb-May. Nest a globular mass of rootlets and moss, set in mossy tangle or epiphyte. Clutch 2 eggs; incubation and fledging periods not documented.

Movements. Resident; many descend to lower elevations in winter.

Status and Conservation. Not globally threatened. Fairly common to common. Especially common in W Chiriquí highlands, in Panama. Occurs in Columbia River Forest Reserve, in Belize, and in Rancho Naturalista, Río Negro Jaguar Reserve, Tapantí National Park and Tarcol Lodge, all in Costa Rica. Considered to be one of the most important dispersers of seeds for a number of plant species of humid forest.

Bibliography. Anon. (1998a), Beavers *et al.* (1991), Blake (1958), Cory & Hellmayr (1927), Davidar (1987), Dickey & van Rossem (1938), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Howell & Webb (1995a), Land (1970), Lanyon (1988b), Lee Jones (2004), Lee Jones *et al.* (2000), Meyer de Schauensee (1982), Moermond (1985), Monroe (1968), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Skutch (1960, 1985), Slud (1960, 1964), Smithe (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Thurber *et al.* (1987), Traylor (1977, 1982), Wetmore (1941, 1972), Willis (1980), Willis & Eisenmann (1979), Wood *et al.* (1986), Zimmer (1941b).

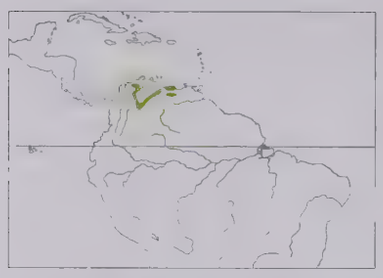
86. **Venezuelan Tyrannulet**

Zimmerius improbus

French: Tyranneau trompeur **Spanish**: Mosquerito Venezolano
German: Küstenkordilleren-Kleintyrann

Taxonomy. *Tyranniscus improbus* P. L. Sclater and Salvin, 1871, Mérida, Venezuela.

Despite superficial resemblance to *Phyllomyias*, genus appears to be more closely related to *Phylloscartes*. This species was formerly placed in a separate genus, *Tyranniscus*, but exhibits plumage and morphological features (wing pattern, proportionally long tail and bill, and derived characters of both syrinx and palate) typical of present genus. Previously considered conspecific with *Z. vilissimus*, but differs in plumage, voice and habitat. Three subspecies recognized.



Subspecies and Distribution.

Z. i. improbus (P. L. Sclater & Salvin, 1871) - N Colombia (Norte de Santander) and NW Venezuela (Táchira, Mérida, Barinas).

Z. i. tamae (Phelps, Sr & Phelps, Jr, 1954) - N Colombia (Santa Marta Mts) and W Venezuela (Sierra de Perijá and Paramo de Tamá, in Táchira).

Z. i. petersi (Berlepsch, 1907) - N Venezuela from S Lara E to Miranda.

Descriptive notes. 11·5 cm; 10-11 g. Nominate race has sharply defined, curved white supercilium contrasting with brown immediately anterior to eye, white partial lower eyering; crown dark brown, upperparts olive; wings dusky, wing-coverts, inner remiges and proximal parts of outer remiges nar-

rowly edged yellow-green ("wedge" of dark feathers between coverts and remiges); tail dusky olive; auricular patch dark brown, contrasting sharply with white throat; breast flammulated olive-grey, flanks olive to olive-grey, belly medium to bright yellow; iris dark brown; bill small and rounded, black; legs black. Sexes similar, female slightly smaller and shorter tailed than male. Juvenile undescribed. Race *tamae* differs only slightly from nominate, being slightly paler yellow below; *petersi* is distinctive, with grey or greyish-brown crown, dark grey auricular patch, pure grey breast, white belly. Voice. Distinctive, loud series of 3-4 sad-sounding, slightly descending whistled notes, each slightly lower-pitched than preceding one, "wheeyr-wheeyr-wheeyr-wheeyr", given only sporadically, separated by long silences; also a duet, one bird giving single whistle, second answering with whistled series; call note a short, high-pitched buzz.

Habitat. Humid montane forest, forest borders, and tall second growth with clearings; mainly 1200-2400 m, but down to 400 m in coast range of N Venezuela, and up to 3000 m in Andes and Sierra de Perijá.

Food and Feeding. Insects, also regularly mistletoe (Loranthaceae) and other small berries. Forages singly or in pairs, often following mixed-species flocks in forest mid-storey and canopy. Actively hops and flits about in outer foliage, perching with horizontal posture, tail often cocked slightly above horizontal; perch-gleans and sally-gleans.

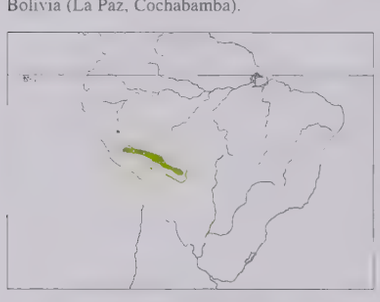
Breeding. Birds in breeding condition in Mar-Nov in Venezuela (Sierra de Perijá). No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to common. Although extensive forest cover survives in parts of its limited range, deforestation has been severe around residential areas, e.g. Caracas (Venezuela), as well as in many other areas.

Bibliography. Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Meyer de Schauensee (1966), Ridgely & Tudor (1994), Stotz *et al.* (1996), Strewe & Navarro (2003), Traylor (1977), Zimmer (1941b).

87. Bolivian Tyrannulet



Zimmerius bolivianus

French: Tyranneau de Bolivie **German**: Olivkleintyrann **Spanish**: Mosquerito Boliviano

Taxonomy. *Muscicapara boliviana* d'Orbigny, 1840, Yungas, Bolivia.

Despite superficial resemblance to *Phyllomyias*, genus appears to be more closely related to *Phylloscartes*. Birds from C & S Peru named as race *viridissimus*, on average perhaps slightly yellower below than those in Bolivia, but individual and age-related variation in this character appears greater than any detectable geographical difference. Monotypic.

Distribution. E Andes from C Peru (Huanuco, N Ayacucho, Cuzco, Madre de Dios, Puno) S to N Bolivia (La Paz, Cochabamba).

Descriptive notes. 12 cm; 10-11·6 g. Exceedingly drab tyrannulet with no facial markings. Has crown, upperparts and face dark olive; wings dark dusky, wing-coverts, inner remiges and proximal parts of outer remiges narrowly edged bright yellow-green ("wedge" of dark remiges separating inner secondaries and primaries); tail dusky olive; throat whitish, breast greyish-olive to yellowish-olive, grading to pale yellow on belly and undertail-coverts; iris creamy white; bill small and rounded, black, lower mandible sometimes deep reddish, purple or grey; legs black. Sexes similar, female slightly smaller than male. Juvenile has reddish to brownish-red iris. Voice. A series of high, thin whistled notes, ascending and at end suddenly falling, "wheee, wheee, wheee, wheee-o", or simply 1-2 of the ascending notes without terminal syllable.

Habitat. Humid montane forest, including mossy cloudforest, also adjacent second growth and clearings; 1000-2830 m.

Food and Feeding. Insects; also small fruits, especially of mistletoe (Loranthaceae). Forages singly or in pairs in forest canopy; sometimes joins mixed-species flocks. Moves about actively, perch-gleaning and sally-gleaning.

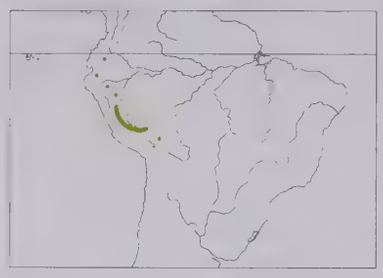
Breeding. Not documented.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Peruvian and East Andean Foothills EBA and Bolivian and Peruvian Lower Yungas EBA. Fairly common to common. Is easily found along the Shintuya-Paucartambo road in Cuzco (Peru) and in the Yungas of Bolivia; occurs also in Machu Picchu Historical Sanctuary, in Peru, and in all protected areas in the Yungas of La Paz and Cochabamba, in Bolivia.

Bibliography. Álvarez & Whitney (2001), Chapman (1921), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Hennessey & Gómez (2003), Hennessey, Herzog & Sagot (2003), Lanyon (1988b), Meyer de Schauensee (1982), Remsen *et al.* (1982), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1977), Walker (2001), Zimmer (1941b).

88. Red-billed Tyrannulet



Zimmerius cinereicapilla

French: Tyranneau à bec rouge **Spanish**: Mosquerito Piquirrojo
German: Purpurschnabel-Kleintyrann

Taxonomy. *Phyllomyias cinereicapilla* Cabanis, 1873, Monterico, Ayacucho, Peru.

Despite superficial resemblance to *Phyllomyias*, genus appears to be more closely related to *Phylloscartes*. This species was formerly placed in a separate genus, *Tyranniscus*, but exhibits plumage and morphological features (wing pattern, proportionally long tail and bill, and derived characters of both syrinx and palate) typical of present genus. Monotypic.

Distribution. Locally in E Andean foothills in NC & SE Ecuador (W Napo, Zamora-Chinchipe), NC, C & SE Peru (Amazonas, San Martín, Junín and Ayacucho S to Cuzco and Madre de Dios) and N Bolivia (La Paz).

Descriptive notes. 11·5-12 cm; 11-13 g. Has short whitish supercilium, grey forehead, crown and lores, and dull olive upperparts; wings dusky, wing-coverts and proximal parts of flight-feathers narrowly edged yellow ("wedge" of dark remiges separating inner secondaries and primaries); tail dusky olive; face olive, throat narrowly whitish, upper breast olive-yellow, remaining underparts bright yellow; iris yellow; bill distinctive, rather large, upper mandible brownish, lower mandible purplish-red; legs grey. Sexes alike, female slightly smaller than male. Juvenile undescribed. Voice. Ascending series beginning and ending with more emphatic notes, including "wheet-wheet?" at end; also single soft "cheet".

Habitat. Humid montane and foothill forest, favouring edges and openings; 750-1350 m.

Food and Feeding. Insects; also small fruits, including those of mistletoes (Loranthaceae). Forages alone or in pairs, occasionally but not habitually following mixed-species flocks. Moves actively through dense outer vegetation in forest canopy, tail often held at or above horizontal, wings flicked occasionally; perch-gleans and hover-gleans.

Breeding. Not documented.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Ecuador-Peru East Andes EBA and Peruvian and East Andean Foothills EBA. Rare to locally fairly common; often overlooked. Apparently rare, with disjunct range, in Ecuador; only one specimen, from W Napo, but observed a few times along road to Loreto N of Archidona and the Archidona Natural Reserve, and one reliable record from SE (lower Loja-Zamora road). More numerous in Peru. Sound recordings obtained from N Bolivia (Serranía de Establón, in La Paz). Many forests within the species' range are threatened by logging, mining, agriculture and road-building, but some large protected areas exist, including Podocarpus and Sangay National Parks, both in Ecuador; in Peru, Manu National Park and Biosphere Reserve and the Apurímac Reserved Zone also protect some of these forests.

Bibliography. Álvarez & Whitney (2001), Barnes *et al.* (1997), Cory & Hellmayr (1927), Cracraft (1985), Davies *et al.* (1994), Hennessey, Herzog & Sagot (2003), Lanyon (1988b), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Stotz *et al.* (1996), Traylor (1977), Zimmer (1941b).

89. Mishana Tyrannulet

Zimmerius villarejoi

French: Tyranneau de Villarejo **Spanish**: Mosquerito de Villarejo
German: Mishima-Kleintyrann
Other common names: Mishima Tyrannulet

Taxonomy. *Zimmerius villarejoi* Álvarez and Whitney, 2001, Allpahuayo-Mishana Reserve, south bank of River Nanay, 25 km WSW of Iquitos, Loreto, Peru.

Despite superficial resemblance to *Phyllomyias*, genus appears to be more closely related to *Phylloscartes*. This recently described species is apparently closest to *Z. cinereicapilla*. Monotypic.

Distribution. N Peru (near Iquitos, in N Loreto).

Descriptive notes. 10·5 cm; 6-7 g. Plumage is entirely greenish-olive above, paler green face, throat and upper breast contrasting only weakly with upperparts; wings dusky, wing-coverts edged and tipped yellow (two thin wingbars), inner remiges narrowly edged yellow; tail dusky, edged yellowish-olive; breast olive-yellow, remaining underparts bright yellow; iris creamy white; bill conical, upper mandible medium brownish, lower mandible dull pink, gape yellow; legs bluish-black, soles of feet yellowish. Sexes alike, female slightly smaller than male. Juvenile undescribed. Voice. Most commonly a closely spaced pair of thin, rising, whistled notes each 0·3 seconds in duration, sometimes given as single note or as triplet; also a more complex, multisyllabic, descending series; dawn song a simple series of 2-4 evenly spaced whistled notes, each progressively shorter than the preceding one.

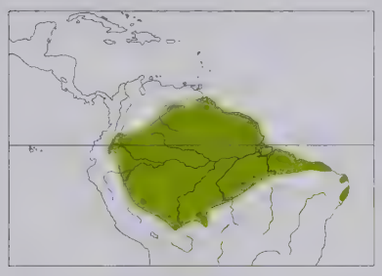
Habitat. White-sand forest consisting of stunted, scrub-like trees and shrubs with canopy 12-18 m (*varillal*); indicator tree species include *Dicymbe uaiparuensis* (Facaceae) and several species of *Caraipa* (Clusiaceae). Lowlands.

Food and Feeding. Insects and, especially, small fruits; favours berries of mistletoe (Loranthaceae), seeds of which it regularly regurgitates and wipes on branches. Stomach contents revealed seeds of legumes and of the melastome *Miconia*. Forages singly or in pairs; rarely joins mixed-species flocks. Moves in canopy and subcanopy with short hops and flights; wings often flicked outwards, tail held downwards but occasionally flicked up towards horizontal. Food items obtained by sally-gleaning.

Breeding. No information.

Movements. Resident; highly sedentary within, and faithful to, small territories.

Status and Conservation. Not globally threatened. Described as recently as 2001; uncommon, has hitherto been found only at type locality of Allpahuayo-Mishana Reserved Zone, 25 km WSW of Iquitos (Loreto), where 1-3 individuals encountered per day; exact provenance of a single specimen labelled "Moybamba, Peru" is uncertain. Appears to be dependent on white-sand forest (*varillal*) in Amazonian Peru; Allpahuayo-Mishana encompasses 57,667 ha of this rare, endangered and fragile habitat. The species' tiny global range, coupled with continuing extraction of trees for building purposes, may threaten its survival. Moreover, a recent illegal invasion by a group of land speculators further threatens the integrity of the reserve, which has insufficient staff and finances to deal with the problem; several thousand hectares have already been destroyed. The few appropriate forests outside the reserve are unprotected and heavily exploited for timber, but future ecotourism and international funding for research and public-awareness campaigns may help with the protection of the reserve. Conservation status of this species needs to be assessed by official conservation bodies.



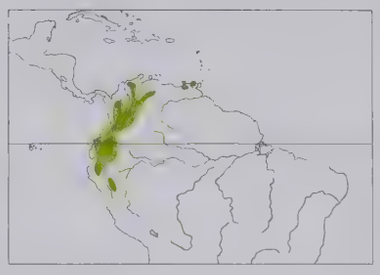
Bibliography. Álvarez & Whitney (2001), Anon. (2001f), Green (2002b), Lowen (2002b), Traylor (1977), Whitney & Álvarez (1998).

90. Slender-footed Tyrannulet

Zimmerius gracilipes

French: Tyranneau à petits pieds **Spanish**: Mosquerito Patifino
German: Schlankfuß-Kleintyrann

Taxonomy. *Tyranniscus gracilipes* P. L. Sclater and Salvin, 1868, Pebas, Peru.
Despite superficial resemblance to *Phyllomyias*, genus appears to be more closely related to *Phylloscartes*. This species was formerly placed in a separate genus, *Tyranniscus*, but exhibits plumage and morphological features (wing pattern, proportionally long tail and bill, and derived characters of both syrinx and palate) typical of present genus. Differences among named populations extremely subtle, apparently clinal, and recognizable only as population averages; on the other hand, apparent vocal differences across range imply that more than one taxon may be involved; further study required. Three subspecies recognized.
Subspecies and Distribution.
Z. g. gracilipes (P. L. Sclater & Salvin, 1868) - SE Venezuela (S Bolívar, Amazonas), extreme E Colombia (Vichada S to Amazonas), NW Brazil (Amazonas), E Ecuador and NE Peru (Loreto).
Z. g. acer (Salvin & Godman, 1883) - the Guianas and NE Brazil (E Amazonas E to Maranhão, Ceará and Alagoas).
Z. g. gilvus (J. T. Zimmer, 1941) - W & S Amazonian Brazil (Amazonas S to Rondônia and N Mato Grosso), C & SE Peru and N Bolivia (S to Cochabamba and N Santa Cruz).



Descriptive notes. 10·5 cm; 6·5-9 g. Nominate race has narrow whitish supraloral stripe and short supercilium, dark eyestripe, grey forehead and crown, dull olive upperparts; wings dusky, wing-coverts and proximal parts of flight feathers narrowly edged yellow ("wedge" of dark remiges separating inner secondaries and primaries); tail dusky olive; throat and lower face yellowish-white, grading to dull olive-yellow on breast and yellow on belly; iris greyish; bill small and rounded, black; legs dark greyish. Sexes alike, female slightly smaller than male. Juvenile undescribed. Race *acer* has almost pure white face and lower throat, paler yellow underparts; *gilvus* has brighter yellow underparts. Voice. Most often heard is a single soft "chwit" or "what?" given from high in canopy, sometimes throughout day; also an ascending series of 4-5 short, slurred notes, "chu, chu-chu-ree" with abrupt rise at end; dawn song an often repeated "tu, de-de", first note descending, second and third notes much higher.
Habitat. Humid lowland evergreen forest and forest edge, and adjacent clearings; mostly below 500 m, but recorded to 850 m in SE Peru, occasionally higher (to 1200 m).
Food and Feeding. Insects; also small fruits, especially of mistletoe (Loranthaceae). Forages extremely high in forest canopy, thus difficult to observe; sometimes joins mixed-species flocks. Moves about actively, obtaining food items by perch-gleaning and sally-gleaning.
Breeding. Birds in breeding condition in Jun in S Colombia and Aug-Dec in SE Peru. Nest a rounded dome with a side entrance. Clutch 2 eggs; incubation and fledging periods not recorded.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to common; often overlooked, encountered mainly by voice. Occurs in many national parks and other protected areas throughout its reasonably large range, including Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela; Tinigua National Park, in Colombia; La Selva and Sacha Lodges, in Ecuador; Manu National Park and Biosphere Reserve, and Tambopata-Candamo Reserved Zone, in Peru; Madidi and Noel Kempff Mercado National Parks and Pilón Lajas Biosphere Reserve, in Bolivia; and some ten or more protected areas in Brazil. Much of this species' habitat remains in relatively pristine condition.
Bibliography. Allen (1995), Álvarez & Whitney (2001), Bangs & Penard (1918), Bates & Parker (1998), Beebe *et al.* (1917), Blake (1950), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Friedmann (1948), Gilliard (1941), Haffer (1997b), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Marchant (1960), Meyer de Schauensee (1982), Munn (1985), Oren & Parker (1997), Pacheco & Whitney (1995), Peres & Whittaker (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Roda & Carlos (2003), Schulenberg *et al.* (2001), Sick (1993, 1997), Silveira *et al.* (2003), Snethlage (1935), Snyder (1966), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992), Traylor (1977), Zimmer (1941b).

91. Golden-faced Tyrannulet

Zimmerius chrysops

French: Tyranneau à face d'or **Spanish**: Mosquerito Caridorado
German: Goldgesicht-Kleintyrann
Other common names: Loja Tyrannulet (*flavidifrons*)

Taxonomy. *Tyrannulus chrysops* P. L. Sclater, 1859, Zamora, Zamora-Chinchipe, Ecuador.
Despite superficial resemblance to *Phyllomyias*, genus appears to be more closely related to *Phylloscartes*. This species was formerly placed in a separate genus, *Tyranniscus*, but exhibits plumage and morphological features (wing pattern, proportionally long tail and bill, and derived characters of both syrinx and palate) typical of present genus. Often treated as conspecific with *Z. viridiflavus*, but separated on basis of plumage and voice. Races *albigularis* and *flavidifrons* possibly represent a separate species. Proposed race *molestus* (described from Cauca, in W Andes of Colombia) merged with nominate. Five subspecies recognized.
Subspecies and Distribution.
Z. c. minimus (Chapman, 1912) - N Colombia (Santa Marta Mts, N Magdalena).
Z. c. cumanensis (J. T. Zimmer, 1941) - NE Venezuela (Anzoátegui, Sucre, Monagas).
Z. c. chrysops (P. L. Sclater, 1859) - Sierra de Perijá and Andes of NW Venezuela, Colombia (except Nariño), E Ecuador and N Peru (S to San Martín).
Z. c. albigularis (Chapman, 1924) - SW Colombia (Nariño) and W Ecuador (S to Guayas).
Z. c. flavidifrons (P. L. Sclater, 1860) - SW Ecuador (SE Guayas S to W Loja).

Descriptive notes. 10·5-11·5 cm; 10·5 g. Brightly coloured tyrannulet with distinctively golden-yellow face and dark eyes. Nominate race has bright yellow forehead, supercilium and orbital region, bright olive upperparts; wings dusky, wing-coverts and flight-feathers edged bright yellow ("wedge" of dark remiges separating inner secondaries and primaries); tail dusky; throat and lower face yellowish-white, grading to dull whitish on breast, flanks and belly; iris brown; bill small and rounded, blackish; legs grey. Sexes alike, female slightly smaller than male. Juvenile undescribed. Races *albigularis* similar but slightly smaller and less yellow than nominate, with whitish throat; *flavidifrons* also has whitish throat, less extensive yellow on lores and forehead, generally darker and duller; *cumanensis* has underparts distinctly washed with pale greenish-yellow; *minimus* is considerably smaller than all others. Voice. Highly vocal, repeatedly uttering ringing whistled "pleeeeur" or "hueeer"; also ringing "teer-tif", especially at dawn, also plaintive "chu-dee-de-e-e", and slow "cheee cheee cheee" repeated 4-5 times; birds in SW Ecuador (*flavidifrons*) said to have dramatically different voice, a drawn-out "truuu-eeet".
Habitat. Humid montane forest, forest borders, older second-growth forest, and coffee plantations, also gardens; mainly 500-2000 m, and recorded to 2700 m. Usually replaced at higher elevations by *Z. improbus*.
Food and Feeding. Insects; regularly eats mistletoe (Loranthaceae) and other small berries. Forages singly or in pairs, often following mixed-species flocks in forest canopy. Actively hops and flits about in outer foliage, perching with horizontal posture, tail often cocked slightly above horizontal. Food items obtained by perch-gleaning and sally-gleaning.
Breeding. Prolonged nesting season, Apr-Nov in Colombia. Dome-shaped nest with side entrance, tucked into hanging moss 8-12 m above ground. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common. Occurs in several protected areas, including e.g. Tambito Nature Reserve, in Colombia, Yacambú National Park, in Venezuela, Machalilla and Podocarpus National Parks, Loma Alta Ecological Reserve and Río Palenque Science Centre, all in Ecuador, and Northwest Peru Biosphere Reserve, in Peru.
Bibliography. Blake (1962), Chapman (1917c), Cory & Hellmayr (1927), Cracraft (1985), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Haffer (1975), Hilty (1997, 2003), Hilty & Brown (1986), Lanyon (1988b), Meyer de Schauensee (1966), Miller (1963), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996), Strewe (2000b), Strewe & Navarro (2003), Traylor (1977), Williams & Tobias (1994), Zimmer (1941b).

92. Peruvian Tyrannulet

Zimmerius viridiflavus

French: Tyranneau à face jaune **German**: Gelbstreif-Kleintyrann **Spanish**: Mosquerito Peruano
Other common names: Tschudi's Tyrannulet

Taxonomy. *E[laenia] viridiflava* Tschudi, 1844, Tulumayo, Junín, Peru.
Despite superficial resemblance to *Phyllomyias*, genus appears to be more closely related to *Phylloscartes*. This species was formerly placed in a separate genus, *Tyranniscus*, but exhibits plumage and morphological features (wing pattern, proportionally long tail and bill, and derived characters of both syrinx and palate) typical of present genus. Often treated as conspecific with *Z. chrysops*, but separated on basis of plumage and voice. Monotypic.
Distribution. E Andes of C Peru (Huanuco, Junín, Ayacucho).

Descriptive notes. 12 cm; 9-10 g. Has pale yellow loral bands meeting narrowly over bill, pale yellow broken eyering, bright olive auricular patch washed with buff; bright olive above, crown darker olive to greyish-olive; wings dark dusky, wing-coverts, inner remiges and proximal parts of outer remiges conspicuously edged bright yellow-green ("wedge" of dark remiges separating inner secondaries and primaries); tail dusky olive; throat pale yellow, breast and flanks olive-yellow, flammulated with olive, belly bright yellow; iris grey to medium brown centrally, rimmed with tan; bill small and rounded, upper mandible grey to blackish, lower mandible medium grey; legs dark grey to black. Sexes alike. Juvenile undescribed. Voice. Rapid whistled phrase, "pee-diddle-wééo", delivered many times in succession.
Habitat. Humid montane forest and forest edge, occasionally in second growth; 1000-2500 m.
Food and Feeding. Insects; probably also mistletoe (Loranthaceae) and other small berries. Forages singly or in pairs, often following mixed-species flocks in forest canopy. Actively hops and flits about in outer foliage, perching with horizontal posture, tail often cocked slightly above horizontal. Food obtained by perch-gleaning and sally-gleaning.
Breeding. Not documented.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Northeast Peruvian Cordilleras EBA. Uncommon to fairly common. Fairly common in Cerros del Sira and Yanachaga-Chemillén National Park and along the Huánuco-Tingo María road in Carpish Mts, in Huánuco. Cordilleras in which this species occurs have suffered widespread deforestation resulting from agricultural expansion, especially in Marañón drainage; although cloudforests are still in relatively pristine condition, recent coca cultivation poses a threat.

Cabanis & Heine, 1859

93. **Mottle-cheeked Tyrannulet**

Phylloscartes ventralis

French: Tyranneau ventru **German**: Olivgelb-Laubtyrann **Spanish**: Orejerito Oliváceo

Taxonomy. *Muscicapa ventralis* Temminck, 1824, Ipanema, São Paulo, Brazil.
Forms a superspecies with *P. flavovirens* and *P. virescens*, all formerly treated as conspecific; *P. kronei* and *P. beckeri* (both recently described) apparently belong with this group. Geographical differences minimal, and the maintaining of races perhaps unwarranted. Three subspecies recognized.
Subspecies and Distribution.
P. v. angustirostris (d'Orbigny & Lafresnaye, 1837) - E Andes from N Peru (San Martín) S to N Bolivia (La Paz, Cochabamba).
P. v. tucumanus J. T. Zimmer, 1940 - NW Argentina (Jujuy S to Tucumán and Catamarca).
P. v. ventralis (Temminck, 1824) - SE Brazil (Minas Gerais and Rio de Janeiro S to S Mato Grosso do Sul and Rio Grande do Sul), E Paraguay, NE Argentina (Misiones, Entre Ríos) and Uruguay.

Descriptive notes. 12 cm; 9 g. Nominate race is dark olive above, narrow short supercilium and eyering whitish (sometimes indistinctly so), dusky eyeline from lores through auriculars, sometimes extending to form shallow crescent at rear, dusky moustachial stripe; wings dusky, two pale yellow to yellow wingbars, yellow edges of flight-feathers, innermost remiges broadly tipped pale yellow on outer webs; tail dusky olive; throat whitish, lower face grizzled whitish; underparts medium yellow, faintly flammulated with olive on breast, belly medium yellow; iris dark brown; bill long and pointed, black, basal half of lower mandible flesh-coloured; legs grey. Sexes alike. Juvenile is duller than adult. Races vary in colour intensity: *angustirostris* is slightly darker green above and richer yellow below than nominate; *tucumanus* is slightly paler olive above, paler yellow below. Voice. Various short, rapid chatters of weak, reedy notes on same pitch, "chidit-it-it-it-it"; also slightly more deliberate "pst-pst-pst".
Habitat. Primarily montane evergreen forest from 1000 m to 2200 m in Andes, rarely above 1500 m in S Brazil; occasionally up to mossy, ridgetop cloudforest, or down to borders of upper tropical forest, treefall gaps and older second growth, rarely to scattered trees in forest clearings. In S part of range, also found in humid tropical forest, gallery forest, and temperate *Araucaria* and *Podocarpus* forests.
Food and Feeding. Arthropods. Stomach contents of specimens from SE Peru contained 52 identified items, of which beetles (Coleoptera) 64%, homopteran bugs 12%, arachnids (spiders) 6%, hemipterans 6%, hymenopterans 7% (ants 4%, wasps 3%), other arthropods 5%. Often forages alone or in pairs, and juveniles forage with parents for many months; also joins mixed-species flocks, but less regularly than do most other members of genus, and moves in and out of flocks. Forages very actively for insects in dense vegetation, mainly at middle and upper levels of humid forest, sometimes in forest understorey where sufficiently dense or low in stature; perches horizontally, carries tail nearly horizontal or slightly cocked, and holds or flicks wings slightly out from body; restless, rarely pauses for longer than 1-2 seconds. Makes short sallies to leaf surfaces to snatch or hover-glean prey, often at outer or terminal twigs and leaves. Changes of perch and sallies within vegetation often accompanied by audible wing-whirring.
Breeding. Oct-Dec in Argentina; juveniles in Nov in SE Peru. Nest in Argentina (race *tucumanus*) a closed ball, circular side entrance protected by short protruding canopy, all made of fibres and vine tendrils, dead leaves, lichens and moss, with mass of fibres protruding under opening, total dimensions 24 × 11 × 9·5 cm, attached below horizontal branch amid jumble of twigs; nest of race *angustirostris* had circular side entrance leading to vertical chamber 6 cm deep near top of bulky, hanging tangle made entirely of the epiphyte *Tillandsia usneoides* ("old man's beard"). Clutch 3 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common. Occurs in a number of protected areas in most parts of range, including e.g. Machu Picchu Historical Sanctuary, in Peru, San Rafael and Ybycuí National Parks, in Paraguay, Itatiaia and Serra da Canastra National Parks and Serra Paranapiacaba International Biosphere Reserve, in Brazil, and Calilegua National Park, in Argentina.
Bibliography. Aspiroz (2001), Begazo (1995), Belton (1985), Brooks *et al.* (1993), Canevari *et al.* (1991), Chapman (1921), Clay, Tobias *et al.* (1998), Cory & Hellmayr (1927), Cracraft (1985), Dabbene (1919), Dubs (1992), Ferreira de Vasconcelos (2001), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Gonzaga & Pacheco (1995), Hayes (1995), Klimaitis (1984), Klimaitis & Moschione (1987), Lowen *et al.* (1996), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988), Raposo *et al.* (2002), Remsen & Traylor (1989), Ridgely & Tudor (1994), Saibene *et al.* (1996), Schulenberg *et al.* (2001), Sick (1993, 1997), Smyth (1928), Stotz *et al.* (1996), Traylor (1977), Weske (1972), Willis & Oniki (1992), Zimmer (1930, 1940b).

94. **Restinga Tyrannulet**

Phylloscartes kronei

French: Tyranneau de Krone **German**: Uferlaubtyrann **Spanish**: Orejerito de Restinga

Taxonomy. *Phylloscartes kronei* Willis and Oniki, 1992, Jardim Europa, Ilha Comprida, São Paulo, Brazil.
Recently described species, apparently belonging to a superspecies that also contains *P. ventralis*, *P. beckeri*, *P. flavovirens* and *P. virescens*; extremely similar to first of those, and possibly only a well-marked race of it, but the two have quite dissimilar voices and different habitats, and occur in close proximity to one another in SE Brazil. Monotypic.
Distribution. Coastal lowlands of SE Brazil from SE São Paulo (including lower banks of R Ribeira) S to Santa Catarina (Joinville).

Descriptive notes. 12 cm; 8-9 g. Plumage is greenish-olive above, slightly browner on crown, narrow supercilium and eyering yellow, dusky eyeline from lores and above auriculars extending at rear to form distinct dusky auricular crescent; face mottled dusky and yellowish; wings dusky, two wingbars and edges of flight-feathers pale yellow to yellow, innermost remiges broadly tipped pale yellow on outer web; tail dusky olive; lower face and throat pale yellow; underparts medium yellow, faintly flammulated with olive on breast, belly medium yellow; iris brown; bill thin and pointed, black, basal two-thirds of lower mandible whitish; legs grey. Sexes alike. Juvenile is duller than adult. Voice. Frequently repeated "feesee" or "plea", and twittering rapid song decribed as "sit-it-it-it-it-it it-sitit-sitit".
Habitat. Coastal sand-ridge and beach woodland (*restinga*); also found in second-growth habitats on same soil formations, and adjacent riverine forest, but only near sea-level.
Food and Feeding. Arthropods. Forages singly or in pairs; often joins mixed-species flocks containing parulids, tanagers (Thraupidae) and other tyrannids. Forages actively in outer foliage of small trees and bushes; tail carried nearly horizontal (not so highly cocked as in *P. ventralis*). Sallies short distances to leaf surfaces to snatch or hover-glean prey.
Breeding. Nest with two nestlings in Oct and family groups and dependent young observed in Dec suggest breeding season Sept-Dec. Nest oven-shaped, covered with lichen and moss, c. 13 cm wide and 16 cm high, placed 1·3 m off ground in small bush in swampy *restinga* vegetation.
Movements. Resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in Atlantic Forest Lowlands EBA. Fairly common, but has relatively small range of c. 5500 km². Global population c. 2500-10,000 individuals. Pairs appear to maintain territories spaced only 100-200 m apart, suggesting density of 1 pair/ha. Threatened by ongoing coastal development, notably on Comprida I. for beachfront dwellings, with consequent extensive habitat loss leading to fragmentation and rapid decrease of its already small population; protection of habitat on Comprida, recently connected to mainland by a bridge, is urgently required if this species is to persist. Ribeira Valley is also rapidly losing its riverine forests and even second growth. Fires also a constant threat to suitable habitat. Occurs in Cananéia-Iguape-Peruíbe Environmental Protection Area, Ilha do Cardoso State Park (with little suitable habitat), Ilha do Superagüi National Park and Patrimônio Natural de Volta Velha Special Reserve.
Bibliography. Bencke *et al.* (2000), Clay, Tobias *et al.* (1998), Collar *et al.* (1994), Forrester (1993), Pacheco & Laps (2001), Remold & Ramos Neto (1995), Ridgely & Tudor (1994), do Rosário (1996), Stattersfield & Capper (2000), Stotz *et al.* (1996), Willis & Oniki (1992).

95. **Bahia Tyrannulet**

Phylloscartes beckeri

French: Tyranneau de Becker **German**: Bahialaubtyrann **Spanish**: Orejerito de Bahía

Taxonomy. *Phylloscartes beckeri* Gonzaga and Pacheco, 1995, Boa Nova, Bahia, Brazil.
Recently described species, apparently belonging to a superspecies that also contains *P. ventralis*, *P. kronei*, *P. flavovirens* and *P. virescens*; seems to be closest to first two of those. Monotypic.
Distribution. S Bahia, in E Brazil.

Descriptive notes. 12 cm; 7·5-9 g. Plumage is bright olive-green above, crown feathers greyish at centre; narrow supraloral stripe and eyering buffy, becoming creamy whitish behind eye; dusky eyeline from lores back to border of yellowish auriculars, extending to form indistinct auricular crescent; wings dusky olive, two wingbars and edges of flight-feathers pale yellow, innermost remiges edged and broadly tipped pale yellow on outer webs; tail dusky olive; throat and breast dirty whitish, flecked with pale yellow, rest of underparts medium yellow, faintly flammulated with olive on side of breast; iris dark brown; bill long and pointed, brown, lower mandible pearly whitish on basal two-thirds; legs pale grey. Sexes alike. Juvenile undescribed. Voice. Short, very soft "tik" contact calls between members of pair, and variable but equally soft, twittery song containing short trills.
Habitat. Primary forest and old secondary evergreen forest in highlands, at 750-1200 m.
Food and Feeding. Stomach contents of four specimens contained only insects. Forages actively in canopy and upper edges of tallest trees, almost always in company of mixed-species flocks. Scans leaf surfaces, often cocks tail to or above horizontal, including rapid flicking nearly to vertical; sallies to snatch or hover-glean insects from leaf surfaces.
Breeding. Not documented. Season probably Sept-Feb.
Movements. Resident.

On following pages: 96. Yellow-green Tyrannulet (*Phylloscartes flavovirens*); 97. Olive-green Tyrannulet (*Phylloscartes virescens*); 98. Ecuadorian Tyrannulet (*Phylloscartes gualaquizae*); 99. Black-fronted Tyrannulet (*Phylloscartes nigrifrons*); 100. Alagoas Tyrannulet (*Phylloscartes ceciliae*); 101. Rufous-browed Tyrannulet (*Phylloscartes superciliaris*); 102. Rufous-lored Tyrannulet (*Phylloscartes flaviventris*); 103. Cinnamon-faced Tyrannulet (*Phylloscartes parkeri*); 104. Minas Gerais Tyrannulet (*Phylloscartes roquettei*); 105. Bay-ringed Tyrannulet (*Phylloscartes sylviolus*); 106. Sao Paulo Tyrannulet (*Phylloscartes paulista*); 107. Oustalet's Tyrannulet (*Phylloscartes oustaleti*); 108. Serra do Mar Tyrannulet (*Phylloscartes difficilis*); 109. Variegated Bristle-tyrant (*Pogonotriccus poecilotis*); 110. Chapman's Bristle-tyrant (*Pogonotriccus chapmani*); 111. Marble-faced Bristle-tyrant (*Pogonotriccus ophthalmicus*); 112. Southern Bristle-tyrant (*Pogonotriccus eximius*); 113. Spectacled Bristle-tyrant (*Pogonotriccus orbitalis*); 114. Venezuelan Bristle-tyrant (*Pogonotriccus venezuelanus*); 115. Antioquia Bristle-tyrant (*Pogonotriccus lanyoni*).

Status and Conservation. ENDANGERED. Restricted-range species: present in Atlantic Forest Mountains EBA. Known from only three localities: small forest remnants in Serra do Ouricana (near Boa Nova), Itatingui and the Chapada Diamantina National Park. Global range no more than c. 1500 km². Threatened by rapid clearance of forests through expansion of pastureland and cultivation. The few privately owned and mostly highly disturbed forest remnants in Serra da Ouricana held c. 10 pairs, but are under severe pressure from clearance and the spreading of fires from cultivated areas; by 1999, largest remaining patch, of c. 3 km², had been largely destroyed, and long-term survival of this species in the area is highly questionable. Bulk of its population is found within the relatively large Chapada Diamantina National Park, in which it has been recorded in three different places; the park's forests are largely in pristine condition, but threatened by illegal charcoal-burning, random settlement and clearance (logging trucks are a fairly common sight). This tyrannid's global population of a few thousand individuals is likely to decline rapidly in the near future, unless effective protection of Chapada Diamantina and surrounding forests is achieved, or new populations are found between there and Boa Nova.

Bibliography. Anon. (1995b, 2000b, 2003f), Clay, Tobias *et al.* (1998), Gonzaga & Pacheco (1995), Gonzaga *et al.* (1995), Parrini *et al.* (1999), Raposo *et al.* (2002), Stattersfield & Capper (2000), Stotz *et al.* (1996).

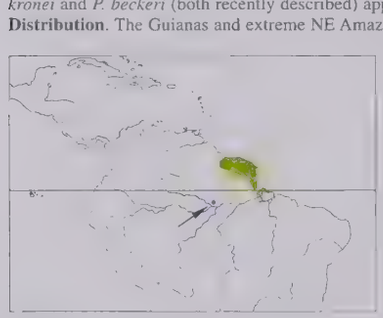
96. Yellow-green Tyrannulet

Phylloscartes flavovirens

French: Tyranneau jaune-vert **German**: Panamalaubtyrann **Spanish**: Orejerito Verdiamarillo

Taxonomy. *Leptopogon flavovirens* Lawrence, 1862, Panama Railroad, Panama.
Forms a superspecies with *P. ventralis* and *P. virescens*, all formerly treated as conspecific; *P. kronei* and *P. beckeri* (both recently described) apparently belong with this group. Monotypic.
Distribution. E Panama, from Canal Zone E to Darién.

Descriptive notes. 12 cm; 8 g. Plumage is olive above, crown same colour as back; supraloral region faintly grizzled whitish and connecting with prominent white eyering; lores and narrow line behind eye dusky, face otherwise yellowish-green; wings dusky, two yellow wingbars, margins of remiges narrowly edged yellow; tail olive; entire underparts bright yellow; iris brown; bill long, pointed, black; legs grey. Sexes alike. Juvenile not described. VOICE. Short, high "pweet!" or "ptwit!", sometimes followed by short chatter of high, thin notes.
Habitat. Montane evergreen forest, from 900 m to 2000 m, occasionally to borders of upper tropical forest, treefall gaps, and older second growth, rarely to scattered trees in forest clearings.
Food and Feeding. Arthropods. Forages very actively in humid forest canopy, usually in mixed-species flocks. Perches horizontally, tail carried nearly horizontal or slightly cocked, wings held or flicked slightly out from body, sometimes one wing quickly raised over back and then lowered. Restless; makes short sallies to leaf surfaces to snatch or hover-glean prey.
Breeding. No published information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Not well known. Regularly observed on Chiva Chiva road and at Madden Lake; possibly occurs also across Panama border, in N Colombia.



Bibliography. Anon. (1998a), Cory & Hellmayr (1927), Eisenmann (1955), Fitzpatrick & Stotz (1997), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Stotz *et al.* (1996), Traylor (1977), Wetmore (1972).

97. Olive-green Tyrannulet

Phylloscartes virescens

French: Tyranneau verdâtre **German**: Guayanalaubtyrann **Spanish**: Orejerito Verdoso

Taxonomy. *Phylloscartes virescens* Todd, 1925, Pied Saut, French Guiana.
Forms a superspecies with *P. ventralis* and *P. flavovirens*, all formerly treated as conspecific; *P. kronei* and *P. beckeri* (both recently described) apparently belong with this group. Monotypic.
Distribution. The Guianas and extreme NE Amazonian Brazil (Amapá); also near Manaus.

Descriptive notes. 12 cm; 8 g. Plumage is olive above, crown same colour as back; supraloral region faintly yellowish-white, connecting with prominent yellowish eyering; face yellowish-green; wings dusky, two medium-yellow wingbars, margins of remiges narrowly edged yellow; tail olive; entire underparts medium yellow; iris brown; bill long, pointed, black; legs grey. Sexes alike. Juvenile not described. VOICE. Song, by both members of foraging pair, a series of high, reedy notes preceded by louder, exclamatory note, "Queet!-peet-peet-peet-peet"; loud introductory note also frequently given singly, sometimes followed by disorganized chatter.
Habitat. Canopy and borders of humid evergreen forest, usually high in primary forest but occasionally in tall second growth and along treefall gaps; at c. 500 m.
Food and Feeding. Arthropods. Usually joins mixed-species flocks containing greenlets (*Hylophilus*), tanagers (Thraupidae), antbirds (Thamnophilidae), and other tyranids. Forages very actively in uppermost foliage of tall trees, tail carried nearly horizontal or slightly cocked, wings held slightly out from body; sometimes raises one wing. Sallies short distances to leaf surfaces to snatch or hover-glean prey.
Breeding. No data. Season probably Dec-Mar.
Movements. Resident.
Status and Conservation. Not globally threatened. Rare; perhaps often overlooked. Occurs in Brownsberg Nature Park, in Surinam; numerous recent sight records from near Manaus, in Brazil. Poorly known; range possibly extends into E Venezuela. Published record from W of R Negro (Manacapuru) involved a misidentified individual. Thought not to be at any risk, as much of its habitat remains undisturbed.

Bibliography. Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Cracraft (1985), Fitzpatrick & Stotz (1997), Forrester (1993), Haverschmidt (1968), Haverschmidt & Mees (1994), Naka (2004), Parker *et al.* (1993), Ridgely & Tudor (1994), Snyder (1966), Stotz (1990b), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977).

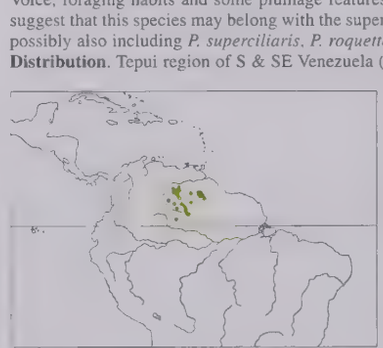
98. Ecuadorian Tyrannulet

Phylloscartes gualaquizae

French: Tyranneau d'Équateur **Spanish**: Orejerito Ecuatoriano
German: Graukronen-Laubtyrann
Other common names: Ecuadorian Bristle-tyrant

Taxonomy. *Pogonotriccus gualaquizae* P. L. Sclater, 1887, Gualaquiza, Morona-Santiago, Ecuador.
Originally included in genus *Pogonotriccus*, but behaviour typical of present genus, with which former was for a time merged. Monotypic.
Distribution. Forested E Andes of Ecuador (S from N Sucumbíos and W Napo) and N Peru (San Martín).

Descriptive notes. 11·5 cm; 8 g. Has grey crown, indistinct whitish supercilium and eyering; face and auriculars pale yellow to whitish, indistinct blackish auricular crescent; upperparts olive, wings dusky, two pale yellow wingbars, margins of remiges edged and tipped pale yellow; tail olive; throat whitish, underparts bright yellow, lightly suffused with olive on breast; iris brown; bill long, pointed, black; legs grey. Sexes alike. Juvenile undescribed. VOICE. High and thin, including single thin "feeee", and thin wheezy trill that descends, ascends, then descends again.
Habitat. Humid montane and upper tropical forest in Andean foothills, mainly below mossy cloud-forest zone; 700-1400 m.
Food and Feeding. Little known. Diet probably arthropods. Forages singly or in pairs, almost always with mixed-species flocks, very high in canopy of tall forest, only rarely descending at forest edges. Restless and active forager, perches horizontally, carries tail nearly horizontal or slightly cocked, frequently holds or flicks wings slightly out from body; sometimes flicks one wing high over back.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Ecuador-Peru East Andes EBA. Uncommon to locally fairly common; often overlooked. Range possibly extends N into S Colombia. In Ecuador, fairly common in Serranías Cofán (Sucumbíos) and occurs in Podocarpus National Park; fairly common in R Afluente region, in Peru. Many forests within the species' range are threatened by logging, mining, agriculture and road-building, but some large protected areas exist (e.g. Podocarpus and Sangay National Parks, both in Ecuador).



Bibliography. Cory & Hellmayr (1927), Graves (1988a), Hornbuckle (1999), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robbins *et al.* (1987), Stotz *et al.* (1996), Traylor (1977).

99. Black-fronted Tyrannulet

Phylloscartes nigrifrons

French: Tyranneau à front noir **Spanish**: Orejerito Frentinegro
German: Schwarzstirn-Laubtyrann

Taxonomy. *Leptopogon nigrifrons* Salvin and Godman, 1884, Roraima, 5000 feet [c. 1520 m], "British Guiana" = Venezuela.
Voice, foraging habits and some plumage features (dark lores and forehead, white nasal plumes) suggest that this species may belong with the superspecies formed by *P. flaviventris* and *P. parkeri*, possibly also including *P. superciliaris*, *P. roquettei* and *P. sylviolus*. Monotypic.
Distribution. Tepui region of S & SE Venezuela (Amazonas, S Bolívar) and adjacent Guyana.

Descriptive notes. 12·5 cm; 10-11 g. Has dark grey crown, black forehead and narrow loral line, white nasal plumes and narrow supercilium; face and auriculars grizzled white and blackish, bordered above and behind by black auricular crescent; upperparts dark olive, wings blackish, two wide, pale yellow wingbars, margins of remiges faintly edged light olive-yellow; tail olive; throat mottled grey and white, breast pale grey, belly pale yellowish-white; iris brown; bill long, pointed, black; legs grey. Sexes alike. Juvenile undescribed. VOICE. High, sharp notes; also high, thin trill with 2 introductory notes and descending near end, "tsuk-cheez-tr-r-r-r-r-r-r-r-r-r-r-r", also shorter version, also ending in brief trill, "chek-chek-ch'leet!".
Habitat. Humid montane forest and dense, taller second growth, mainly below the wettest, mossy cloudforest; 800-1800 m.
Food and Feeding. Insects; possibly also small fruits such as *Miconia*, as sometimes found in dense melastome (Melastomataceae) thickets. Almost always in pairs, or with additional juveniles, in mixed-species flocks. Forages very actively, in upper and outer canopy. Perches horizontally, tail carried horizontal or slightly cocked, occasionally flicked downwards while foraging; wings frequently held or flicked slightly out from body, sometimes one wing flicked high over back. Restless, rarely pauses for more than 1-2 seconds; makes short sallies to leaf surfaces to snatch or hover-glean prey, often at outer or terminal twigs and leaves.
Breeding. No data.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Uncommon to fairly common; fairly common on Sierra de Lema, in E Bolívar. Occurs in Canaíma National Park, in Venezuela. Range believed to extend into adjacent parts of N Brazil. Tepuis within its range are rather unaffected by human disturbance owing to their inaccessibility, and much suitable habitat remains. Vegetation on tepuis, however, is especially sensitive to fire and

other disturbances; in addition, gold-prospectors and uncontrolled tourism have recently had severe local impacts.
Bibliography. Chapman (1931), Cory & Hellmayr (1927), Cracraft (1985), Hilty (2003), Mayr & Phelps (1967), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Stotz *et al.* (1996), Willard *et al.* (1991).

100. Alagoas Tyrannulet

Phylloscartes ceciliae

French: Tyranneau de Cecilia **German**: Alagoaslaubtyrann **Spanish**: Orejerito de Alagoas
Other common names: Long-tailed Tyrannulet

Taxonomy. *Phylloscartes ceciliae* Teixeira, 1987, Serra Branca, Murici County, Alagoas, Brazil.
Apparently close to the superspecies formed by *P. flaviventris* and *P. parkeri*, possibly also including *P. nigrifrons*, *P. superciliaris*, *P. roquettei* and *P. sylviolus*. Monotypic.
Distribution. Alagoas, in NE Brazil.

Descriptive notes. 11-12 cm; 7-8 g. Plumage is dark olive-green above; whitish supercilium, spot below eye and auriculars, auriculars and eye spot bordered by ashy black "bridle" connecting with broad blackish eyeline; wings blackish-olive, edged yellowish green, wing-coverts broadly tipped greenish-yellow (two wingbars), outer margins of inner remiges broadly edged and tipped yellowish-green; tail blackish, edged yellowish-green; throat and breast whitish, breast side washed with dark green, remaining underparts white, faintly washed pale yellow on belly and undertail-coverts; iris chestnut-brown; bill pointed, black; legs dark bluish-grey. Sexes alike. Juvenile undescribed. Voice. Peeping sequence of "dju" notes, sometimes sharper and faster, "ururut, ururut..."; soft "thup" call note.
Habitat. Remnant highland evergreen forest, also mature second growth, in Atlantic Forest region; 400-550 m.
Food and Feeding. Insects. Often joins mixed-species flocks containing other tyrannids, furnariids, dendrocolaptids and antbirds (Thamnophilidae). Forages actively in middle and upper canopy of tall trees, tail carried cocked at or above horizontal; sallies to leaf surfaces to snatch or hover-glean prey.
Breeding. Not documented; moult cycle of the few specimens suggests breeding between Sept and Feb.
Movements. Resident.
Status and Conservation. CRITICAL. Restricted-range species: present in Atlantic Slope of Alagoas and Pernambuco EBA. Locally fairly common. Known from only three localities, two of which on SE escarpment of Borborema Plateau; first discovered in 1983, on slopes of Pedra Branca, near Murici, where considered to be rather common at type locality. Forests around Murici reduced from 70 km² in 1970s to a mere 30 km² in 1999; only c. 2% of original forests remain in Alagoas and Pernambuco, and these highly disturbed and severely fragmented, and still threatened by small-scale cultivation, firewood-gathering, and spreading of fires from adjacent plantations; further logging, with associated new roads, was evident in 1999, eradicating forest even on steep slopes. Some forest protected in the Murici Ecological Reserve (30 km²), but most of surrounding land privately owned, and a number of conservation initiatives have so far failed to halt further forest loss; best areas now lie almost exclusively within the privately managed 1200-ha Fazenda Bananeira. In late 1980s, the species was also found at Pedra Talhada State Park (45 km²), where significant areas are being reforested with native trees; protection at this reserve is enforced by guards and apparently welcomed by local communities, but during 15 days of observations between 1996 and 1999 the species was found on only three occasions. In 2003, it was also recorded at the 630-ha Patrimônio Natural Frei Caneca Private Reserve, in Pernambuco, thus extending its range and improving its chances of survival. Further searches may locate additional sites in Pernambuco and Alagoas, e.g. at Usina Serra Grande.
Bibliography. Clay, Tobias *et al.* (1998), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Goerck (2001), Kirwan *et al.* (2001), Lowen (2001), Raposo *et al.* (2002), Ridgely & Tudor (1994), Roda *et al.* (2003), Sick (1993, 1997), Silveira *et al.* (2003), Stattersfield & Capper (2000), Stotz *et al.* (1996), Stuart (2003), Teixeira (1987), Vuilleumier *et al.* (1992), Wege & Long (1995).

101. Rufous-browed Tyrannulet

Phylloscartes superciliaris

French: Tyranneau à sourcils roux **Spanish**: Orejerito Cejirrufo
German: Weißwangen-Laubtyrann

Taxonomy. *Leptotriccus superciliaris* P. L. Sclater and Salvin, 1868, Chitrá, Veraguas, Panama.
Was once included in genus *Mecocerculus*. Vocal similarities and plumage (rufous above lores) suggest that it is possibly a member of the superspecies formed by *P. flaviventris* and *P. parkeri*, perhaps also including *P. nigrifrons*, *P. roquettei* and *P. sylviolus*. Geographical variation minor; validity of races impossible to assess, as so few specimens available. Three subspecies tentatively recognized.
Subspecies and Distribution.
P. s. superciliaris (P. L. Sclater & Salvin, 1868) - forested mountains of Costa Rica and W Panama.
P. s. palloris (Griscom, 1935) - E Panama (Darién).
P. s. griseocapillus Phelps, Sr & Phelps, Jr, 1952 - very locally in NW Venezuela (Sierra de Perijá), Colombia (E Andes, possibly also Chocó region) and E slopes in SE Ecuador (Cordillera de Cutucú, Cordillera del Condor).
Descriptive notes. 12 cm; 7-8 g. Nominate race has pearly grey crown, bright chestnut frontal band and narrow supercilium, pure white spot at base of bill, white auricular patch conspicuously encircled with black and, posteriorly, with chestnut; upperparts bright olive; wings dusky olive, edged yellow-green, tail dusky olive; lower face grizzled whitish, throat greyish-white, underparts white, tinged yellow-green on flanks and faintly yellowish on belly and undertail-coverts; iris dark brown; bill black; legs dark grey. Sexes alike. Juvenile undescribed. Races differ only slightly: *palloris* has crown darker than nominate and slightly suffused with brownish, duller olive back, paler grey breast, almost pure white belly; *griseocapillus* has darker grey crown, darker chestnut lores, brighter green back, pale yellow undertail-coverts. Voice. Calls and sings frequently, with lively series of sharp, high pitched notes, "swee-swee-swee"; single, sharp "swik" delivered at irregular intervals.

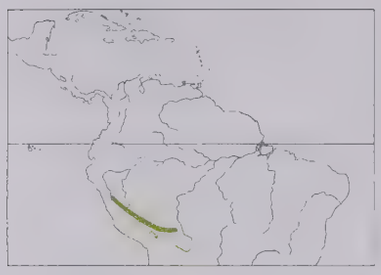
Habitat. Humid montane forest, occasionally venturing to forest edges and treefall openings; at 600-1200 m in Costa Rica and Panama, 1600-2000 m in Colombia, Venezuela and Ecuador.
Food and Feeding. Insects; small fruits (*Miconia*, *Trema*) sometimes taken. Almost always forages in pairs or small family parties, in mixed-species flocks. Forages very actively, very high in upper and outer canopy, lower at edges and openings; seemingly favours trees with small leaves, where forages at outer perimeters; perches horizontally, tail carried nearly horizontal or slightly cocked, wings frequently held or flicked slightly out from body, sometimes one wing flicked high over back. Restless, rarely pauses for more than 1-2 seconds; makes short sallies to leaf surfaces to snatch or hover-glean prey, often at outer or terminal twigs and leaves.
Breeding. No confirmed data; believed to breed in Mar-Jun in Costa Rica.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common, and very local. A poorly known species. Occurs in Rancho Naturalista and Río Negro Jaguar Reserve, both in Costa Rica. Range possibly extends S into N Peru.
Bibliography. Anon. (1998a), Cory & Hellmayr (1927), Cracraft (1985), Eisenmann (1955), Fitzpatrick & Stotz (1997), Gonzaga & Pacheco (1995), Hilty (2003), Hilty & Brown (1986), Kirwan *et al.* (2001), Meyer de Schauensee (1982), Negret (2001), Raposo *et al.* (2002), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Traylor (1977), Wetmore (1972).

102. Rufous-lored Tyrannulet

Phylloscartes flaviventris

French: Tyranneau masqué **German**: Rostzügel-Laubtyrann **Spanish**: Orejerito Amarillo
Other common names: Yellow-bellied Bristle-tyrant

Taxonomy. *Leptotriccus flaviventris* Hartert, 1897, Mérida, Venezuela.
Forms a superspecies with *P. parkeri*, possibly also including *P. nigrifrons*, *P. superciliaris*, *P. roquettei* and *P. sylviolus*. Monotypic.
Distribution. N Venezuela: Yaracuy and coastal mountains from W Carabobo E to Distrito Federal, also interior Miranda (Cerro Negro). Also reported in past from Mérida, but probably erroneously.



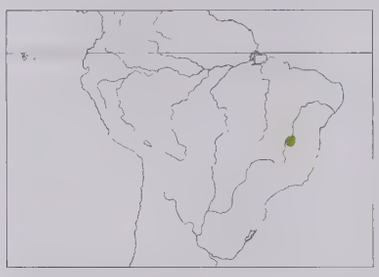
Descriptive notes. 12 cm; 8 g. Plumage is dark olive above, crown slightly darker than back; prominent rufous forehead and supraloral stripe, becoming yellow stripe behind eye, bordered below by blackish lores and moustachial region; rufous broken eyering; yellowish auriculars bordered above and behind by black crescent; wings blackish, two bright yellow wingbars, margins of remiges broadly edged and tipped bright yellow; tail olive; entire underparts bright yellow; iris brown; bill long, pointed, black; legs grey. Sexes alike. Juvenile undescribed. Voice. A short, rapid series of high, thin notes, "tseep-tseep-tseep", sometimes ending with more emphatic "seet".
Habitat. Montane evergreen forest, often venturing to forest edges and montane roadcuts bordered by tall trees; usually in tall upper tropical forest, only rarely up slopes to mossy ridgetop cloudforest. From 300 m to 1200 m.
Food and Feeding. Insects recorded in diet. Almost always forages in pairs or small family parties, in mixed-species flocks. Forages very actively, in middle and upper canopy of humid forest; perches horizontally, with tail carried nearly horizontal or slightly cocked, and wings frequently held or flicked slightly outwards from body. Restless, rarely pauses for more than 1-2 seconds; makes short sallies to leaf surfaces to snatch or hover-glean prey, often at outer or terminal twigs and leaves.
Breeding. No confirmed data; family groups observed in Feb.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Occurs in Guatopo and Henri Pittier National Parks (especially numerous around Rancho Grande and Maracay-Choroní road). Although extensive forest cover still exists in parts of its limited range, deforestation has been severe around residential areas, e.g. Caracas, as well as in many other areas.
Bibliography. Cory & Hellmayr (1927), Fitzpatrick & Stotz (1997), Gonzaga & Pacheco (1995), Hilty (2003), Kirwan *et al.* (2001), Meyer de Schauensee (1982), Raposo *et al.* (2002), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1977), Visbal *et al.* (1996).

103. Cinnamon-faced Tyrannulet

Phylloscartes parkeri

French: Tyranneau de Parker **German**: Zimtgesicht-Laubtyrann **Spanish**: Orejerito de Parker

Taxonomy. *Phylloscartes parkeri* Fitzpatrick and Stotz, 1997, Hacienda Amazonía, Madre de Dios, Peru.
Recently described, although long known from a single specimen collected in 1899. Forms a superspecies with *P. flaviventris*, possibly also including *P. nigrifrons*, *P. superciliaris*, *P. roquettei* and *P. sylviolus*. Monotypic.
Distribution. Forested E Andes from C Peru (Huánuco and Pasco) S to extreme N Bolivia (S Beni).
Descriptive notes. 12 cm; 8 g. Has medium-grey crown, prominent cinnamon-rufous forehead and supraloral stripe becoming yellow to yellowish-white stripe behind eye; white nasal plumes, rufous broken eyering; pale cinnamon face and auricular patch, bordered above and behind by black auricular crescent; upperparts olive, wings blackish, two bright yellow wingbars, margins of remiges broadly edged and tipped bright yellow, tail olive; entire underparts bright yellow; iris brown; bill long, pointed, black; legs grey. Sexes alike. Juvenile resembles adult. Voice. Calls and sings fre-



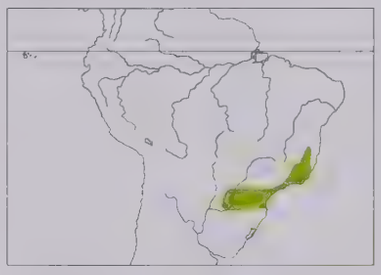
quently, with high, emphatic "tsit!" notes, occasionally delivered in rapid series followed by sharp ascending and then descending trill, "tsit-tsit-tsr-r-r-e-e-e-r-r-r-r".
Habitat. Montane evergreen forest, rarely venturing to forest edges; remains in highest portions of canopy in tall upper tropical forest, occasionally up slopes to mossy ridgetop cloudforest. From 700 m to 1200 m.
Food and Feeding. Arthropods. Stomach contents from SE Peru included 63 identified items, of which beetles (Coleoptera) 38%, homopteran bugs 18%, hymenopterans 32% (ants 16%, wasps 16%), hemipterans 5%, flies (Diptera) 3%, spiders (Araneae) 3%, lepidopterans 1%. Almost always forages in pairs or small family groups, in mixed-species flocks. Forages very actively, very high in upper and outer canopy, seemingly favouring trees with small leaves and foraging at their outer perimeters. Perches horizontally, with tail carried nearly horizontal or slightly cocked, wings frequently held or flicked slightly out from body; rapidly alternates orientation on perch by facing one way, and then flipping 180 degrees to face opposite direction. Restless, rarely pauses for more than 1-2 seconds; makes short sallies to leaf surfaces to snatch or hover-glean prey, often at outer or terminal twigs and leaves.
Breeding. Birds with enlarged gonads, and presence of juveniles, in Nov in SE Peru, suggesting breeding Sept-Dec. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Occurs along R Urubamba (below Machu Picchu) and in Manu National Park and Biosphere Reserve, in Peru, and Pilón Lajas Biosphere Reserve and Madidi National Park, in Bolivia. Appears to be confined to primary evergreen forest with intact tall canopy and within narrow elevational range; is therefore sensitive to selective logging and other types of habitat degradation.
Bibliography. Fitzpatrick & Stotz (1997), Green (1998), Hennessey, Herzog & Sagot (2003), Kirwan *et al.* (2001), Raposo *et al.* (2002), Sangster (1998), Schulenberg & Servat (2001), Stotz *et al.* (1996).

104. Minas Gerais Tyrannulet

Phylloscartes roquettei

French: Tyranneau de Minas Gerais **Spanish**: Orejerito de Minas Gerais
German: Gelbbürzel-Laubtyrann

Taxonomy. *Phylloscartes roquettei* E. Snethlage, 1928, Brejo Januária, São Francisco River, Minas Gerais, Brazil.
Affinities uncertain; possibly related distantly to the superspecies formed by *P. flaviventris* and *P. parkeri*, perhaps also including *P. nigrifrons*, *P. superciliaris* and *P. sylviolus*. Monotypic.
Distribution. N Minas Gerais, in E Brazil.



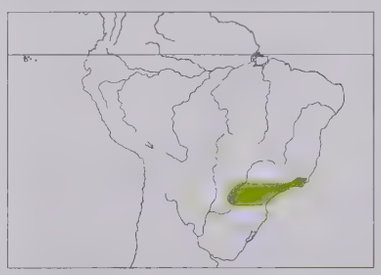
Descriptive notes. 12 cm; c. 8 g. Plumage is olive above, crown same colour as back; prominent rufous to ochraceous forehead and supraloral region, thin buffy broken eyering, blackish lores, yellowish auriculars bordered blackish above and behind; wings dusky, two yellow wingbars, margins of remiges edged and tipped bright yellow; tail olive; entire underparts medium yellow; iris probably brown; bill long, pointed, black, base of lower mandible ashy; legs greyish-brown. Sexes alike. Juvenile resembles adult. Voice. Song a fast series of high, harmonic notes, introductory note slightly louder and higher; calls are individual notes similar to those in song.
Habitat. Tropical dry forest, gallery forest, and tall deciduous scrub, especially those closely associated with river courses; prefers tall emergent trees (remnants of earlier primary forest) within degraded dry or gallery forest.
Food and Feeding. Arthropods. Forages in pairs or family groups, only rarely in mixed-species flocks (unlike many of its congeners), mainly in mid-canopy and upper canopy of taller trees, occasionally descending to lower branches within 2-3 m of ground to forage in denser foliage when in leafless deciduous trees. Active and restless, holding body horizontally or at 45-degree angle, tail slightly above horizontal and bobbing slightly, wings held out or drooped; occasionally raises one wing above back, sometimes followed by other wing (never both together). Makes short sallies to snatch insects from branches and leaves, rarely from air; occasionally reaches to pick prey from leaf surfaces. Movements between perches rarely exceed 1 m, often involving rapid diagonal flight downwards and then looping back to perch on lower branch; "loop" flight sufficiently distinctive to identify the species at a distance in the field.
Breeding. One nest found in Oct; family with fledged young in Feb. Nest roughly globular in shape, approximate dimensions 10 cm tall and 6-7 cm across (when still under construction), short side entrance tube, constructed from fine rootlets, dead twigs, lichens, grassy material and small number of dead leaves, attached almost at extreme tip of small branch c. 10 m above ground in streamside tree and within 1 m of termitarium suspended close to main trunk; both pair-members actively collected material, usually very close to or directly from ground. No further information.
Movements. Apparently resident.
Status and Conservation. CRITICAL. Restricted-range species: present in Deciduous Forests of Minas Gerais and Goiás EBA. Found at only 3-4 localities in mesophytic, semi-deciduous dry forest and gallery forest, probably the most threatened habitat in C & E Brazil owing to its valuable aroeira (*Astronium urundeuva*) timber and relatively fertile soils. First discovered in Jul 1926 and not seen again for 50 years; relocated in 1977 near type locality, but searches there in 1985, 1986 and 1987 were unsuccessful; in 1986, charcoal-burners were fully active, and forests were extensively cut down for timber, limestone quarrying, pasture and cultivation. In 1993 the species was discovered c. 250 km S of type locality, at Várzea da Palma (SE of Pirapora), where it was very rare in 1998, 1999 and 2002, and in 1995 it was found at Francisco Dumont; in this region, a major irrigation project is underway which has already led to the deforestation of large areas. In 2004 it was found 40 km NNE of type locality, in Cavernas do Peruaçu National Park (where possibly recorded earlier, in 1997); this is the only protected area in the species' known range. Unless additional populations are found, or the known and extremely small occupied sites are effectively protected, this tyrannid, which probably numbers no more than a few hundred individuals, is likely to become extinct in the very near future.
Bibliography. Cavalcanti (1988), Clay, Tobias *et al.* (1998), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cracraft (1985), Fitzpatrick & Stotz (1997), Kirwan, Mazar Barnett, Ferreira *et al.* (2004), Kirwan, Mazar Barnett & Minns (2001), Meyer de Schauensee (1982), Raposo *et al.* (2002), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Wege & Long (1995), Willis & Oniki (1991).

105. Bay-ringed Tyrannulet

Phylloscartes sylviolus

French: Tyranneau sylvain **German**: Rostring-Laubtyrann **Spanish**: Orejerito Ojirrojo

Taxonomy. *L[eptotriccus] sylviolus* Cabanis and Heine, 1859, Rio de Janeiro, Brazil.
Was for long treated in a monotypic genus, *Leptotriccus*, but seems typical member of present genus. May belong with the superspecies formed by *P. flaviventris* and *P. parkeri*, possibly also including *P. nigrifrons*, *P. superciliaris* and *P. roquettei*. Monotypic.
Distribution. Extreme E Paraguay, SE Brazil (S Minas Gerais and Espírito Santo S to Santa Catarina) and NE Argentina (Misiones).



Descriptive notes. 12 cm; c. 8 g. Upperparts and crown bright yellowish olive; prominent loral patch and eyering rufous-chestnut, auriculars yellow-green and lacking any contrasting dark patch, but bordered below by pale yellow; wings like back, wing-coverts and remiges edged slightly brighter yellow but wingbars lacking; tail dusky olive; chin buffy-yellow, rest of underparts whitish, tinged light green on upper flanks and pale yellow on undertail-coverts; iris whitish; bill long, pointed, black, base of mandible ashy; legs and feet grey. Sexes alike. Juvenile probably resembles adult. Voice. Song is a fast, complex series of high notes, "swit-swi-swi-swi-swi-deedeedeedee-swi-swi."
Habitat. Humid lowland and foothill evergreen forest and forest edge, to 600 m.
Food and Feeding. Arthropods. Forages alone or in pairs, occasionally in family groups of 3-5 birds, mainly in forest canopy, often in company of mixed species flocks; active and restless while foraging, holding body horizontally with long tail cocked above horizontal and wings often held out or drooped. Makes short sallies to snatch or hover-glean insects from branches and leaves, rarely from air; occasionally reaches to pick insects from leaf surfaces.
Breeding. Aug-Oct in Argentina; adults with fledged young in Feb, in Brazil. Hanging nest with lateral entrance hole, composed mainly of moss and suspended below a horizontal branch 10-16 m above ground. Clutch size and eggs undescribed. No further information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Uncommon to scarce. Occurs in several protected areas, in Brazil including e.g. Iguaçu National Park and Mata dos Godoy State Park (both in Paraná), and Intervales State Park (São Paulo), where rarely observed around Saibadela Research Station but more abundant at upper elevations within the park; in Argentina, regular in forests near Iguazú Falls in Iguazú National Park; and in Paraguay, uncommon at Estancia Itabó Private Nature Reserve, Mbaracayú Forest Nature Reserve, and Caaguazú and San Rafael National Parks. Atlantic Forest continuously threatened by agricultural conversion, mining, urbanization, industrialization, and associated road-building.
Bibliography. Aleixo & Galetti (1997), Brooks *et al.* (1993), Canevari *et al.* (1991), Clay, Tobias *et al.* (1998), Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1927), Fitzpatrick & Stotz (1997), Hayes (1995), Kirwan *et al.* (2001), Lowen *et al.* (1996), Meyer de Schauensee (1982), Madroño & Esquivel (1997), Naka *et al.* (2001), Narosky & Salvador (1998), Narosky & Yzurieta (1993), de la Peña (1988), Pinto (1944), Raposo *et al.* (2002), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993).

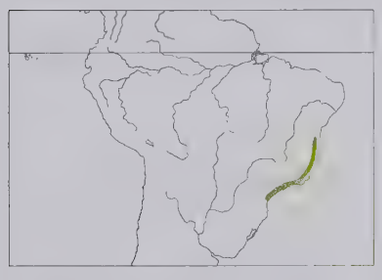
106. Sao Paulo Tyrannulet

Phylloscartes paulista

French: Tyranneau de Sao Paulo **German**: Zwerglaubtyrann **Spanish**: Orejerito de Sao Paulo

Taxonomy. [*Phylloscartes*] *paulista* H. von Ihering and R. von Ihering, 1907, Fazenda Cayoá, Sao Paulo, Brazil.
Monotypic.
Distribution. SE Brazil (SE Mato Grosso do Sul E to Espírito Santo, S to Santa Catarina), E Paraguay and NE Argentina (Misiones).

Descriptive notes. 10·5 cm; 7-8 g. Olive above, crown same colour as back; narrow yellow supercilium extends well behind eye, then down to wrap around broad black auricular crescent; face yellowish; wings dusky olive, two indistinct wingbars and narrow margins of remiges yellowish-olive; tail olive; entire underparts dull yellow, heavily suffused with olive on breast; iris brown; bill long, pointed, black; legs grey. Sexes alike. Juvenile undescribed. Voice. Softly whistled "swee-eet".
Habitat. Humid tropical and upper tropical forest and forest borders, mainly below 500 m, occasionally to 1000 m. Replaced by *P. oustaleti* at upper elevations.
Food and Feeding. Arthropods. Forages singly or in pairs, almost always with mixed-species flocks (which often also contain *Pogonotriccus eximius*), in understorey and mid-storey. Active. Posture nearly upright, less horizontal than that of most congeners, but foraging behaviour equally frenetic, with wings often held slightly out from body, and frequently jerking back and forth 180 degrees on perch. Sallies to snatch or hover-glean insects from leaves and vines, sometimes clambering under leaf clusters.
Breeding. Testes enlarged in Oct and not enlarged in Jan or Apr, season presumably Sept-Dec. No other information.



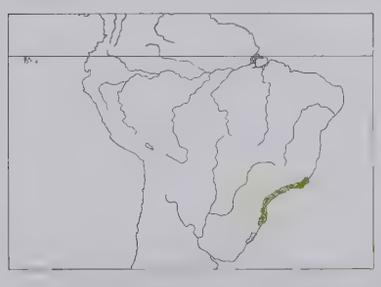
Movements. Resident.
Status and Conservation. VULNERABLE. Rare to uncommon. Found at relatively few sites. Global population probably fewer than 10,000 individuals. Destruction and fragmentation of lowland Atlantic Forest has had devastating effect on this species' habitat; following agricultural conversion and deforestation for coffee, banana and rubber plantations, less than 20% of original forest cover remains intact. In Paraguay alone, 38% of forests disappeared between 1984 and 1991. Remaining forests, even within protected areas, suffer from agricultural expansion, mining, urbanization, industrialization, and associated road-building. In Brazil, the species is fairly common in Intervales State Park (at Saibadela Research Station), in Iguaçu National Park (a few thousand individuals) and in Ilha do Cardoso State Park, and occurs also in at least ten other nominally protected areas; probably locally extinct in Espírito Santo, where no records since 1942. Present also in Caaguazú, San Rafael and Ybycuí National Parks, in Paraguay, and Iguazú National Park, in Argentina, as well as in several other protected areas in both countries.
Bibliography. Aleixo & Galetti (1997), Brooks *et al.* (1993), Buzzetti (2000), Canevari *et al.* (1991), Chebez (1994), Chebez *et al.* (1999), Clay, Tobias *et al.* (1998), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1927), Cracraft (1985), Hayes (1995), Lowen *et al.* (1996), Madroño & Esquivel (1995), Narosky & Yzurieta (1993), de la Peña (1988), Ridgely & Tudor (1994), do Rosário (1996), Scott & Brooke (1985), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993), Wege & Long (1995).

107. **Oustalet's Tyrannulet**

Phylloscartes oustaleti

French: Tyranneau d'Oustalet **German**: Gelbohr-Laubtyrann **Spanish**: Orejerito de Oustalet

Taxonomy. *Leptopogon oustaleti* P. L. Sclater, 1887, "Bogota"; error = probably Corcovado, Rio de Janeiro, Brazil.
Monotypic.
Distribution. Coastal forests of E Brazil from S Bahia S to E Santa Catarina.



Descriptive notes. 12 cm; 8 g. Plumage is olive above, crown same colour as back; lores yellowish, connecting with prominent, wide yellow eyering; face bright yellow near eye, broad auricular crescent blackish, bordered posteriorly with bright yellow; wings dusky olive, wing-coverts tipped yellowish, margins of remiges narrowly edged yellowish-olive; tail olive; entire underparts bright yellow, heavily suffused with olive on breast; iris brown; bill long, pointed, black; legs grey. Sexes alike. Juvenile undescribed. VOICE. Soft 2-note or 3-note call, "ku-dut" or "ku-dut-dut".
Habitat. Humid tropical and upper tropical forest, mainly in interior, only occasionally along dense forest borders; mostly at 500-900 m. Seems to replace *P. paulista* at higher elevations.
Food and Feeding. Arthropods. Usually forages in pairs or family groups, and almost always with mixed-species flocks (which often also contain *Pogonotriccus eximius*), generally in forest canopy and subcanopy. Posture horizontal, wings held slightly drooped or out from body, tail cocked well above the horizontal, sometimes to nearly vertically over back, and almost constantly quivering. Forages actively; sallies to snatch or hover-glean insects from leaves.
Breeding. No data. Season probably Sept-Dec.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Atlantic Forest Lowlands EBA. Locally uncommon to fairly common. Occurs in several protected areas, e.g. Augusto Ruschi Biological Reserve (Espírito Santo), Intervales State Park (São Paulo) and Mata dos Godoy State Park (Paraná); at Intervales, rarely observed around the Saibadela Research Station but more abundant at upper elevations within the park. Forests within this species' range are continuously threatened by agricultural conversion, mining, urbanization, industrialization, and associated road-building.
Bibliography. Aleixo & Galetti (1997), Clay, Tobias *et al.* (1998), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1927), Cracraft (1985), Machado & Rodrigues (2000), Meyer de Schauensee (1982), Pacheco & Whitney (1995), Parker *et al.* (1996), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993), Venturini *et al.* (2001).

108. **Serra do Mar Tyrannulet**

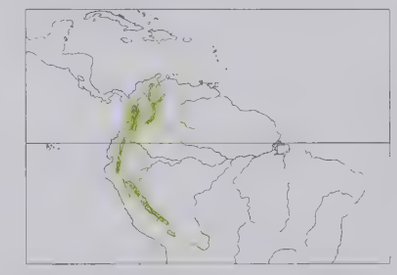
Phylloscartes difficilis

French: Tyranneau d'Ihering **Spanish**: Orejerito de Serra do Mar
German: Olivgrau-Laubtyrann
Other common names: Ihering's Tyrannulet

Taxonomy. *Guracava difficilis* H. von Ihering and R. von Ihering, 1907, Campos do Itatiaia, Rio de Janeiro, Brazil.
Monotypic.
Distribution. SE Brazil, from Minas Gerais and Espírito Santo S to Rio Grande do Sul.

Descriptive notes. 11-11·5 cm; c. 7-8 g. Plumage is bright olive above, with prominent white eyering and supraloral stripe, bordered below by blackish lores and area below eye; face grey, blackish auricular crescent; wings olive, same colour as back, faintly paler along margins of remiges; tail olive; entire underparts medium grey, slightly paler on throat and undertail-coverts; iris brown; bill short, pointed, black, paler at base of lower mandible; legs greyish-pink. Sexes alike. Juvenile undescribed. VOICE. Rapid chatter of thin, rather harsh notes.
Habitat. Humid montane forest and its shrubby borders, from 950 m to 2150 m.
Food and Feeding. Arthropods. Forages singly or in pairs, only rarely with mixed-species flocks, in understorey and dense growth of humid vegetation. Somewhat less active than most congeners, but shares with them the horizontal posture, tail often held slightly above horizontal, wings drooped or held out from body; sallies to hover-glean insects from dense foliage.
Breeding. No data. Season presumably Sept-Jan.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Atlantic Forest Mountains EBA. Uncommon. Observed regularly in Itatiaia National Park. Montane forests within this species' range have suffered less destruction than have adjacent lowland areas, but isolated patches in N have virtually disappeared owing to expansion of pasture and cultivation.
Bibliography. Belton (1985), Buzzetti (2000), Clay, Tobias *et al.* (1998), Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), Gonzaga (2002), Meyer de Schauensee (1982), Parker *et al.* (1996), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993), Traylor (1977).

Genus *POGONOTRICCUS*



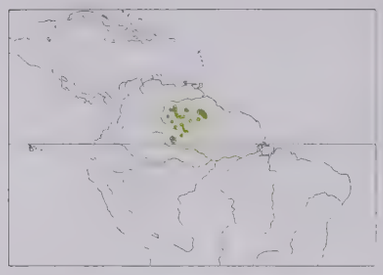
Cabanis & Heine, 1859

109. **Variegated Bristle-tyrant**

Pogonotriccus poecilotis

French: Tyranneau varié **German**: Zimtbinden-Laubtyrann **Spanish**: Orejerito Variegado

Taxonomy. *Leptopogon poecilotis* P. L. Sclater, 1862, "Bogota", Colombia.
Genus previously merged with *Phylloscartes*, and that treatment retained by many authors; despite superficial similarities, however, the two groups differ significantly in foraging behaviour and postures, possibly also in details of nest (little known), and perhaps are not even closely related to one another. Birds from extreme NW Venezuela (Sierra de Perijá) described as race *pifanoi*, supposedly with somewhat more blackish crown, but this difference virtually imperceptible and may represent individual variation. Monotypic.
Distribution. NW Venezuela (Sierra de Perijá, Mérida) and Andes of Colombia, E Ecuador and Peru (Cajamarca and San Martín S, locally, to Puno).



Descriptive notes. 11 cm; 8 g. Has slate-grey crown contrasting with bright yellow-olive upperparts; lores and supercilium grizzled white, supercilium extending back to wrap around black auricular crescent; face yellowish; wings dusky, two broad wingbars bright chestnut-buff, remiges broadly but indistinctly edged buffy; tail dusky olive; throat whitish, underparts bright yellow, washed with olive on breast; iris brown; bill black above, lower mandible orange to yellowish-orange nearly to tip; legs grey. Sexes alike. Juvenile undescribed. VOICE. High, thin "wheee-seet"; also a short, emphatic series of "tsit" notes ending in more emphatic "tsweeet".
Habitat. Humid montane forest, especially wet mossy cloudforest; 1500-2300 m.
Food and Feeding. Arthropods. Forages singly or in pairs, typically in mixed-species flocks (often also containing related *P. ophthalmicus*). Perches in mid-storey and upper branches of mossy forest; posture upright, tail held vertically downwards, frequently lifts or flicks one wing high, then repeats with opposite wing. Feeds with short, outward or upward, looping sallies to snatch or hover-glean insects from undersides of leaves, then rapid flight to new perch.
Breeding. No data.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally common to locally fairly common. Occurs in Tambito Nature Reserve and Ucumarí Regional Park, in Colombia, and in all protected areas along E Andean slope of Ecuador. A single reported record from W Ecuador is considered uncertain.
Bibliography. Aveledo & Pons (1952), Chapman (1917c, 1926), Cory & Hellmayr (1927), Cracraft (1985), Davies *et al.* (1994), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Miller (1963), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1977).

110. **Chapman's Bristle-tyrant**

Pogonotriccus chapmani

French: Tyranneau de Chapman **Spanish**: Orejerito de Chapman
German: Olivkappen-Laubtyrann
Other common names: Chapman's Tyrannulet

Taxonomy. *Phylloscartes chapmani* Gilliard, 1940, Cerro Roraima, 4200 feet [c. 1280 m], Venezuela.
Genus previously merged with *Phylloscartes*, and that treatment retained by many authors; despite superficial similarities, however, the two groups differ significantly in foraging behaviour and postures, possibly also in details of nest (little known), and perhaps are not even closely related to one another. Two subspecies recognized.
Subspecies and Distribution.
P. c. chapmani (Gilliard, 1940) - tepui region of S Venezuela (S Bolívar and N Amazonas) and adjacent Guyana and Brazil.
P. c. duidae (Phelps, Sr & Phelps, Jr, 1951) - Cerros Duida and Neblina in S Venezuela (S Amazonas) and adjoining Brazil.
Descriptive notes. 12 cm; 8 g. Plumage is dull olive above, crown slightly darker olive; ill-defined supraloral stripe whitish, white eyering; black eyeline meeting sharp black auricular crescent behind cheeks; wings dusky, two buffy wingbars, edges of flight-feathers pale buffy yellow to buffy white, innermost secondaries broadly tipped pale buff (forming spots); tail dusky olive; lower face grizzled whitish and grey, throat and breast olive-yellow, rest of underparts pale yellow; iris brown; bill short, pointed, black, paler yellow at base of lower mandible; legs grey. Sexes alike. Juvenile

undescribed. Race *duidae* is paler, more yellow-green, above than nominate, with tips of innermost secondaries darker buff, edges of remiges more yellowish, less buff. Voice. Unknown.

Habitat. Humid montane evergreen forest, especially wet and mossy forest on slopes of tepuis, between 1000 m and 2000 m.

Food and Feeding. Diet unknown; probably insects. Forages in pairs or in (presumably) family groups, typically in mixed-species flocks. Perches in mid-storey of forest; posture upright, tail held vertically downwards; frequently lifts or flicks one wing high. Sallies are usually upwards to hover-glean from undersides of leaves.

Breeding. No data.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Poorly known. Apparently locally common. In Venezuela, rare and local on Sierra de Lema and at top of the Escalera (in E Bolívar), but more numerous on Aprada, Chimantá, Parú, Ptari and Sipapo tepuis; occurs in Canaíma National Park. Tepuis within its range are rather unaffected by human disturbance owing to their inaccessibility, but vegetation is especially sensitive to fire and other disturbances; gold-prospectors and uncontrolled tourism have recently had severe local impacts.

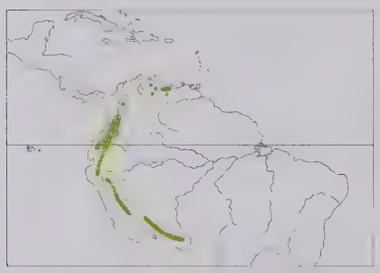
Bibliography. Cracraft (1985), Fitzpatrick & Stotz (1997), Forrester (1993), Hilty (2003), Mayr & Phelps (1967), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Willard *et al.* (1991).

111. Marble-faced Bristle-tyrant

Pogonotriccus ophthalmicus

French: Tyranneau marbré **German**: Schwarzohr-Laubtyrann **Spanish**: Orejerito Jaspeado
Other common names: Otto's Bristle-tyrant

Taxonomy. *Pogonotriccus ophthalmicus* Taczanowski, 1874, Amable María, Chanchamayo Valley, Peru.



Genus previously merged with *Phylloscartes*, and that treatment retained by many authors; despite superficial similarities, however, the two groups differ significantly in foraging behaviour and postures, possibly also in details of nest (little known), and perhaps are not even closely related to one another. Distinctive S race *ottonis* was once considered a separate species. Three subspecies recognized.

Subspecies and Distribution.

P. o. purus Todd, 1952 - coastal and interior mountains of N Venezuela (Yaracuy, and from Carabobo E to Distrito Federal and Aragua).

P. o. ophthalmicus Taczanowski, 1874 - Andes of Colombia (W & C ranges), NW & E Ecuador and E slope in Peru (S to Ayacucho).

P. o. ottonis Berlepsch, 1901 - SE Peru (Cuzco, Madre de Dios) S to N Bolivia (La Paz, Cochabamba, W Santa Cruz).

Descriptive notes. 11·5 cm; 10-11 g. Nominate race has slate-grey crown contrasting with bright yellow-olive upperparts; lores and supercilium white, face grizzled black and white, auriculars white to very pale yellow with broad black crescent at rear; wings dusky, two wingbars and edges of flight-feathers pale olive-yellow to yellow, innermost remiges broadly edged pale yellow on outer web; tail dusky olive; throat grizzled whitish, underparts bright yellow, heavily washed with darkish olive on breast; iris brown; bill black; legs grey. Sexes alike. Juvenile is duller than adult. Races vary mainly in intensity of yellow on face, wings and underparts: *purus* has brighter yellow face than nominate, more prominent wingbars, somewhat brighter yellow underparts; *ottonis* has pale yellow wingbars, greyish white throat and upper breast washed with pale olive, remaining underparts white to very pale yellow. Voice. Song a rather weak but explosive, high-pitched chatter, ending in rapid, slightly ascending trill, "ju-ju-j-j-j tre-e-e-e-e-e- pit-pit"; call a sharp "ju-é" or "ts-rit".

Habitat. Humid montane forest, especially mossy, middle-elevation cloudforest; remains in forest interior, rarely venturing to edges and clearings. At 800-1700 m in Venezuela, mainly 1400-2400 m in Colombia (but down to 600 m on Pacific slope), 1200-2100 m in Ecuador; 1200-1800 m in SE Peru, but down to 750 m on foothill ridges.

Food and Feeding. Arthropods. Most often seen in pairs with mixed-species flocks of tanagers (Thraupidae), warblers (Parulidae), furnariids and other tyrannids. Forages in middle to lower canopy, perching on exposed horizontal branches and twigs to search surrounding vegetation; pauses for 5-30 seconds at each perch, tail held vertically downwards, head actively scanning around and upwards; unsuccessful searches followed by moves of 2-10 m. Prey captured mainly with upward strikes, snatches and hover-gleans, occasionally pursuing dislodged prey briefly before resting on new perch.

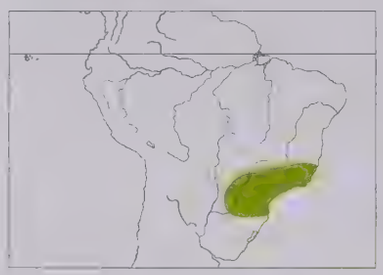
Breeding. Little published information available. Nest-building observed in Jun in Colombia; birds with gonads in reproductive condition, and family groups containing juveniles, in Sept-Dec in SE Peru.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to locally common. Rare at Finca Merenberg (Huila), in Colombia, at upper limit of altitudinal range. Occurs in several protected areas, including Henri Pittier National Park, in Venezuela, Tambito Nature Reserve and Ucumarí Regional Park, in Colombia, Machu Picchu Historical Sanctuary, in Peru, and Pilón Lajas Biosphere Reserve and Madidi National Park, in Bolivia.

Bibliography. Chapman (1917c, 1926), Cory & Hellmayr (1927), Cracraft (1985), Cuervo & Delgado (2001), Davies *et al.* (1994), Hennessey & Gómez (2003), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Miller (1963), Perry *et al.* (1997), Remsen & Traylor (1989), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robbins & Ridgely (1990), Salaman (1994), Salaman *et al.* (2002), Stotz *et al.* (1996), Traylor (1977), Walker (2001), Weske (1972), Wetmore (1939), Zimmer (1930).

112. Southern Bristle-tyrant



Pogonotriccus eximius

French: Tyranneau distingué **German**: Weißzügel-Laubtyrann **Spanish**: Orejerito Cejudo

Taxonomy. *Muscicapa eximia* Temminck, 1822, Ipanema, São Paulo, Brazil.

Genus previously merged with *Phylloscartes*, and that treatment retained by many authors; despite superficial similarities, however, the two groups differ significantly in foraging behaviour and postures, possibly also in details of nest (little known), and perhaps are not even closely related to one another. Monotypic.

Distribution. SE Brazil (S Mato Grosso E to Rio de Janeiro, S to Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).

Descriptive notes. 11 cm; c. 7-8 g. Has grey crown with olive wash at centre, prominent white supraloral stripe and supercilium extending well behind eye, bordered below by blackish lores and stripe through eye back to sharply defined black auricular crescent; rest of face, auricular patch and rear border of facial crescent yellow; upperparts bright olive, wings dusky olive, wing-coverts and margins of remiges broadly but indistinctly edged yellowish-olive; tail olive; throat whitish, underparts bright yellow, breast lightly washed with olive; iris brown; bill short, pointed, black, paler at base of lower mandible; legs grey. Sexes alike. Juvenile undescribed. Voice. Sings and calls frequently with thin, chittery trills that end emphatically.

Habitat. Tropical evergreen and lower montane forest and forest borders, to c. 600 m, and temperate forest, including *Araucaria*-dominated forest and woodland.

Food and Feeding. Arthropods. Usually forages singly or in pairs, only rarely with mixed-species flocks. Perches in mid-storey of forest, posture upright with tail held vertically downwards; inconspicuous, except for frequent calling. Sallies are usually upwards to hover-glean from undersides of leaves.

Breeding. Sept-Jan. Nest bulky, oven-shaped, with side entrance, constructed mainly from mosses. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Uncommon to locally fairly common. Population concentrated principally in basin of R Paraná; has disappeared from São Paulo (Brazil), despite fact that tracts of suitable habitat remain. Occurs in several protected areas, e.g. Iguaçu and Serra da Canastra National Parks and Mata dos Godoy State Park (Paraná), in Brazil, Caaguazú, San Rafael and Ybycuí National Parks, Estancia Itabó Private Nature Reserve and Mbaracayú Forest Nature Reserve, all in Paraguay, and Iguazú National Park, in Argentina. Remaining forests, even within protected areas, suffer from agricultural conversion, mining, urbanization, industrialization, and associated road-building. Montane Atlantic Forest, however, has suffered less than have adjacent lowland forests, and the species' occurrence at these higher altitudes suggests that adequately large tracts of suitable habitat still exist.

Bibliography. Bertoni (1901), Brooks *et al.* (1993), Canevari *et al.* (1991), Clay, Tobias *et al.* (1998), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1927), Dubs (1992), Hayes (1995), Lowen *et al.* (1996), Madroño & Esquivel (1995), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Parker *et al.* (1996), de la Peña (1988), Remold & Ramos Neto (1995), Ridgely & Tudor (1994), do Rosário (1996), Saibene *et al.* (1996), Sick (1993, 1997), Silveira (1998), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993), Traylor (1977), Willis & Oniki (1993).

113. Spectacled Bristle-tyrant

Pogonotriccus orbitalis

French: Tyranneau à lunettes **German**: Augenring-Laubtyrann **Spanish**: Orejerito de Anteojos

Taxonomy. *Capsiempis orbitalis* Cabanis, 1873, Monterico, Peru.

Genus previously merged with *Phylloscartes*, and that treatment retained by many authors; despite superficial similarities, however, the two groups differ significantly in foraging behaviour and postures, possibly also in details of nest (little known), and perhaps are not even closely related to one another. Forms a superspecies with *P. venezuelanus* and *P. lanyoni*. Monotypic.

Distribution. Locally in E Andes of extreme S Colombia S to E Ecuador, and from Peru (S from S Amazonas) S to Bolivia (La Paz, Cochabamba).

Descriptive notes. 11·5 cm; 8 g. Has grey crown, yellowish-white lores and prominent eyering; face and auriculars mottled yellowish, faintly bordered above and behind by indistinct blackish auricular crescent; upperparts olive; wings dusky, wing-coverts tipped pale yellow (two wingbars consisting of rows of distinct spots), remiges edged and tipped pale yellow; tail olive; entire underparts bright yellow, very lightly suffused with olive on breast; iris brown; bill long, pointed, blackish, most of lower mandible whitish to pinkish-white; legs grey. Sexes alike. Juvenile undescribed. Voice. Not very vocal; soft series of "tic" notes rising and falling slightly, sometimes given individually.

Habitat. Humid montane forest, especially in dark, wet ravines and on lower-elevation ridgetops below mossy cloudforest; remains in forest interior, rarely venturing to edges and clearings. Around 900 m in S Colombia, 700-1400 m locally in Ecuador; 600-1200 m in SE Peru, down to 500 m on foothill ridges.

Food and Feeding. Stomach contents from SE Peru contained 66 identified items: beetles (Coleoptera) 56%, homopteran bugs 12%, hymenopterans 23% (ants 12%, wasps 11%), spiders (Araneae) 6%, hemipterans 3%. Forages singly or in pairs, found less often in mixed-species flocks than are congeners and *Phylloscartes* species. Perches mainly in understorey, only rarely to mid-storey or upper branches; posture upright, tail held vertically downwards; frequently lifts or flicks one wing high overhead, then repeats with opposite wing; pauses on perch for 10-30 seconds.

Feeds with short, outward or upward, looping sallies to snatch or hover-glean insects from undersides of leaves, then rapid flight to new perch.
Breeding. Birds with enlarged gonads, and juveniles present, in Oct and Nov in SE Peru, suggesting season Sept-Dec. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally rare, but locally fairly common; easily overlooked. Fairly common in SE Peru; listed as "near-threatened" in Ecuador. Occurs in Pilón Lajas Biosphere Reserve and Madidi National Park, both in Bolivia.
Bibliography. Cory & Hellmayr (1927), Fitzpatrick & Stotz (1997), Graves (1988a), Hennessey, Herzog & Sagot (2003), Hilty & Brown (1986), Jácome (2002a), Meyer de Schauensee (1982), Remsen & Traylor (1989), Ridgely & Tudor (1994), Ridgely & Greenfield (2001), Stotz *et al.* (1996), Traylor (1977).

114. Venezuelan Bristle-tyrant

Pogonotriccus venezuelanus

French: Tyranneau du Venezuela **German**: Karibiklaubtyrann **Spanish**: Orejerito Venezolano

Taxonomy. *Pogonotriccus venezuelanus* Berlepsch, 1907, Puerto Cabello, Carabobo, Venezuela.
Genus previously merged with *Phylloscartes*, and that treatment retained by many authors; despite superficial similarities, however, the two groups differ significantly in foraging behaviour and postures, possibly also in details of nest (little known), and perhaps are not even closely related to one another. Forms a superspecies with *P. orbitalis* and *P. lanyoni*. Monotypic.
Distribution. Coastal cordillera (from Carabobo E to Distrito Federal) and interior mountains (S Aragua, S Miranda) of N Venezuela.

Descriptive notes. 11·5 cm; 8-9 g. Has grey crown, yellowish-white lores and prominent eyering; face and auriculars mottled yellowish, faintly bordered above and behind by indistinct blackish auricular crescent; upperparts olive, wings blackish, two broad pale yellow wingbars, remiges edged and tipped pale yellow; tail olive; throat and entire underparts bright yellow, very lightly suffused with olive on breast; iris brown; bill long, pointed, blackish, basal half of lower mandible whitish; legs grey. Sexes alike. Juvenile undescribed. Voice. Double-note call, "che-dip", and high, fast trill first descending and then ascending.
Habitat. Humid montane forest, especially wet, mossy cloudforest, at 950-1400 m.
Food and Feeding. Forages singly or in pairs, typically in mixed-species flocks (often also containing *P. ophthalmicus*). Perches in mid-storey and upper branches; posture upright, tail held vertically downward; frequently lifts or flicks one wing high, then repeats with opposite wing. Feeds with short, outward or upward, looping sallies to snatch or hover-glean insects from undersides of leaves, then rapid flight to new perch.
Breeding. No data. Season probably Jan-Apr/May.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Cordillera de la Costa Central EBA. Fairly common. Occurs in Henri Pittier National Park, and probably in other protected areas within its small range. Although extensive forest cover still exists in parts of its range, deforestation has been severe around residential areas, e.g. Caracas, as well as in many other areas.
Bibliography. Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), Fitzpatrick & Stotz (1997), Graves (1988a), Hilty (2003), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Traylor (1977), Visbal *et al.* (1996).

115. Antioquia Bristle-tyrant

Pogonotriccus lanyoni

French: Tyranneau de Lanyon **German**: Antioquialaubtyrann **Spanish**: Orejerito Antioqueño

Taxonomy. *Phylloscartes lanyoni* Graves, 1988, El Pescado, Antioquia, Colombia.
Genus previously merged with *Phylloscartes*, and that treatment retained by many authors; despite superficial similarities, however, the two groups differ significantly in foraging behaviour and postures, possibly also in details of nest (little known), and perhaps are not even closely related to one another. Forms a superspecies with *P. orbitalis* and *P. venezuelanus*. Monotypic.
Distribution. E & N slopes of C Andes (in Antioquia and Caldas) and W slope of E cordillera (in Boyacá), in Colombia.

Descriptive notes. 11·5 cm; c. 8 g. Has grey crown, yellowish-white lores and prominent broken eyering; face and auriculars mottled yellowish, faintly bordered above and behind by indistinct blackish auricular crescent; upperparts olive, wings dusky, two broad bright yellow wingbars, remiges edged and tipped pale yellow; tail olive; entire underparts bright yellow, very lightly suffused with olive on breast; iris probably brown; bill long, pointed, blackish, basal half of lower mandible whitish; legs grey. Sexes alike. Juvenile undescribed. Voice. Unknown.
Habitat. Semi-deciduous foothill forest, at 450-900 m.
Food and Feeding. Forages singly or in pairs, often with mixed-species flocks. Little information; diet and behaviour presumably much as for closely related *P. orbitalis* and *P. venezuelanus*.
Breeding. Almost unknown. Nesting recorded in Mar, and family group observed in Jun.
Movements. Resident.
Status and Conservation. ENDANGERED. Restricted-range species: present in Nechí Lowlands EBA. Resticted to a 60-km stretch of middle Magdalena Valley in C Andes and W slope of E Andes in Colombia, and known from only six localities within total range of only c. 600 km². Estimated global population of a few thousands. The species occurs in the 0·2-km² watershed reserve of La Victoria (Caldas) and in the 1-km² Río Claro Reserve (Antioquia); latter helps to prevent human colonization of adjacent forested areas, but lies within an area of heavy logging activity. It is uncommon at El Vergel and common in the 4-km² forest at Monte del Diablo (both in Boyacá); recorded 10 km W of La Victoria, near Tasajos (Caldas). Threatened by rapid habitat loss and fragmentation due to logging, livestock-rearing, arable cultivation, infrastucture development, oil extraction and mining, although some extensive forests survive, and in some areas regeneration has begun following land abandonment. Dependence on undisturbed habitat unknown; has been observed in second growth and disturbed forest. Ecological requirements of this poorly known species urgently needed.
Bibliography. PLATE 23

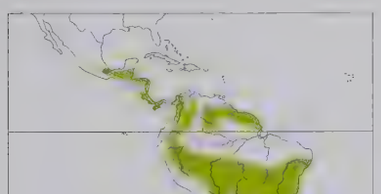
inches 3

cm 8



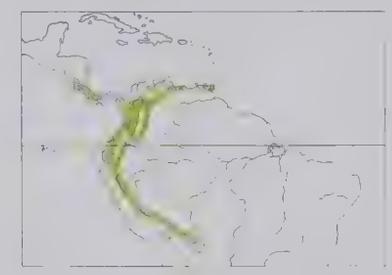
Genus *LEPTOPOGON* Cabanis, 1844

116. Sepia-capped Flycatcher

Leptopogon amaurocephalus

French: Pipromorphe à tête brune **Spanish**: Orejero Coronipardo
German: Braunkappen-Laubtyrann
Other common names: Sepia-capped Leptopogon

Taxonomy. *Lept[opogon] amaurocephalus* Tschudi, 1846, São Paulo, Brazil.
Races may be divided into three plumage types, "nominate group" (also including *pileatus* and *idius*), the single-taxon "*diversus* group" and "*peruvianus* group" (with *orinocensis*); these intergrade with one another, and many specimens from S Mexico closely resemble others from NE Argentina. Differences within populations exceed those alleged to occur among many of the named races; described taxon *faustus* (Nicaragua S to C Panama) indistinguishable from and merged with *pileatus*, and *obscuritergum* (S Venezuela in Amazonas and SE Bolívar) inseparable from and merged with *orinocensis*. Six subspecies recognized.
Subspecies and Distribution.
L. a. pileatus Cabanis, 1865 - humid lowlands from S Mexico and Yucatán Peninsula S to C Panama.
L. a. idius Wetmore, 1957 - Coiba I, off SW Panama.
L. a. diversus Todd, 1913 - NC Colombia (from Santa Marta region and Magdalena Valley S to Tolima) and extreme NW Venezuela (Zulia).
L. a. orinocensis J. T. Zimmer & Phelps, Sr, 1946 - Venezuela (from S Táchira, Barinas and Portuguesa E to Bolívar and Amazonas), the Guianas and N Brazil (Amapá).
L. a. peruvianus P. L. Sclater & Salvin, 1868 - E Colombia (S from Norte de Santander), E Ecuador, E Peru, N Bolivia (Beni, La Paz, Cochabamba), and W Brazil (Amazonas and Rondônia E to N Mato Grosso).
L. a. amaurocephalus Tschudi, 1846 - S & E Brazil (S from Mato Grosso, S Maranhão and Pernambuco), E Bolivia (Santa Cruz S to Tarija), Paraguay and NW & NE Argentina (S to Salta, Jujuy, Misiones and Corrientes).



Descriptive notes. 13·5 cm; 12 g. Nominate race is warm buffy olive above, crown warm sepia-brown; lores mottled whitish; face and auricular patch mottled whitish to pale yellow, bordered posteriorly by broad dark brown facial crescent; wings dusky, most feathers edged dull yellow-green, outer webs of wing-coverts broadly tipped rich cinnamon-buff to pale yellowish-buff (wingbars appearing as two rows of elongated dots), outer edges of innermost remiges broadly cinnamon-buff to pale yellowish-buff; tail dusky olive; throat mottled greyish, merging with broad breastband flammulated with olive, darker breast streaks invade pale yellow underparts; thighs olive; iris medium greyish-brown; bill long, black, base of lower mandible pale grey; legs dark grey. Sexes alike, female on average slightly smaller than male. Juvenile resembles adult. Race *pileatus* has uppertail-coverts and tail strongly tinged warm cinnamon-brown; *idius* is similar to previous but greyer and paler throughout, wingbars less rufescent; *diversus* has upperparts pale dusky olive, underparts and breast flammulations pale; *peruvianus* is dark greyish above, crown darker olive, wingbars and wing edgings pale yellow, underparts pale yellowish-white; *orinocensis* differs from previous in paler, more yellow-grey, breast nearly lacking olive wash. Voice. Squeaky, explosive trill often preceded or followed by 1-2 sharp notes, "skeet-jt-jt-jt-jt-jt!" or "whik, whik, purrrrrrrrr" or ""prip-prrrrrrrip-pjit-pjit"; also softer, descending trill.
Habitat. Lowland tropical forests, from moist evergreen forest and gallery forest to deciduous woodland; in Amazonia, more common in *várzea* and river-edge forests than in interior *terra firme* forest; in S & E Brazil, occupies open woodlands and dense, humid brush. To 1100 m.
Food and Feeding. Arthropods; small fruit and berries also eaten. Two stomachs from Surinam packed with butterfly (Lepidoptera) remains; stomach contents from SE Peru contained 48 food items, of which ants (Hymenoptera) 46%, orthopterans 17%, homopteran bugs (planthoppers) 10%, beetles (Coleoptera) 8%, spiders (Araneae) 6%, pupae (6%), shield-bugs (Pentatomidae) 2%. Forages in shady, leafy settings, usually within 8 m of ground; often joins mixed-species flocks in forest understorey. Perches upright, pauses for 10-30 seconds to search mainly upwards; regularly lifts one wing high over back while perched (rarely, both wings, or one followed by the other). Snatches insect prey with upward hover-gleans and upward strikes.
Breeding. Season Feb-May in Middle America and Aug-Dec in S portion of range. Nest (in Mexico and Brazil) globular, with side entrance, made of fresh moss, dry moss, fine roots and grass, firmly lined with silky seed down, suspended on rootlet under protective log or ledge, often in ravine. Clutch 2-3 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Occurs in many national parks and other protected areas throughout its large range, e.g. Lamanai Archaeological and Columbia River Forest Reserves, in Belize, Laguna del Tigre National Park, in Guatemala, Tinigua National Park, in Colombia, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Madidi and Noel Kempff Mercado National Parks, Beni Biosphere Reserve and Pilón Lajas Biosphere Reserve, in Bolivia, Caaguazú, San Rafael, San Luis and Ybycuí National Parks, all in Paraguay, Iguaçu, Itatiaia, Serra da Canastra and Tijuca National Parks, all in Brazil, Cerro Corá National Park, in Uruguay, and Iguazú National Park, in Argentina. Much of its habitat remains in relatively pristine condition.
Bibliography. Anon. (1998a), Bates & Zink (1994), Begazo (1995), Belton (1985), Binford (1989), Brooks *et al.* (1993), Canevari *et al.* (1991), Chapman (1917c, 1926), Collins & McDaniel (1989), Cory & Hellmayr (1927), Di Giacomo & López (2000), Fitzpatrick (1980c, 1985b), Fjeldså & Maijer (1996), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes (1995), Heinonen *et al.* (1995), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Hudson (1920), Land (1970), Lanyon (1988b), Lee Jones (2004), López *et al.* (1989), Lowen *et al.* (1996), Monroe (1968), Moore (1944), Munn (1985), Narosky & Salvador (1998), Olson (1997), de la Peña (1988), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robinson (1997), Robinson & Terborgh (1997), do Rosário (1996), Sick (1993, 1997), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977), Wetmore (1972), Zimmer (1941c).

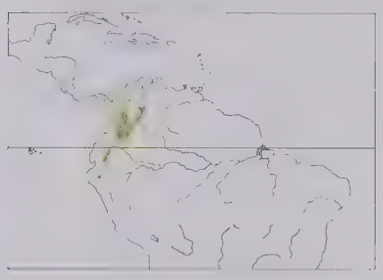
117. Slaty-capped Flycatcher

Leptopogon superciliaris

French: Pipromorphe à tête grise **Spanish**: Orejero Coronigrís
German: Schieferkappen-Laubtyrann
Other common names: Slaty-capped Leptopogon; White-bellied Leptopogon (*albidiventer*)

Taxonomy. *L[eptopogon] superciliaris* Tschudi, 1844, Montaña of Vitoc, Peru.
Most populations exhibit extraordinary individual variation (especially in colour of wingbars), even at a single locality, and majority of named races cannot be distinguished from one another; hence, *hellmayri* (Costa Rica and W Panama), *transandinus* (E Panama, W slope of W Andes of Colombia, W Ecuador), *poliocephalus* (C & E Andes of Colombia), *venezuelensis* (N Venezuela, from W Zulia E to Monagas) and *pariae* (extreme NE Venezuela in Sucre, and Trinidad) all merged with nominate. Transition to distinctive white-bellied race *albidiventer* occurs sharply in E Andes of C Peru, and both plumage types occur together from Ayacucho S to Cuzco; detailed genetic and vocal studies could demonstrate that they represent separate species. Two subspecies recognized.
Subspecies and Distribution.
L. s. superciliaris Tschudi, 1844 - mountains of Costa Rica and Panama, Colombia (all three cordilleras), Venezuela (Andes and coastal mountains, and Paria Peninsula), Trinidad, Ecuador (both slopes) and E Peru (S to Ayacucho).
L. s. albidiventer Hellmayr, 1918 - E Peruvian Andes (S from Ayacucho and Cuzco) and N Bolivia (La Paz, Cochabamba, W Santa Cruz).

Descriptive notes. 13·5 cm; 12 g. Nominate race is dark olive above, crown slaty grey; lores and narrow supercilium white, face and auricular patch mottled whitish, bordered posteriorly by broad black facial crescent; wings dusky, most feathers edged yellow-green, outer webs of wing-coverts broadly tipped rich cinnamon-buff to pale yellow (highly variable, mostly pale yellow to whitish in Venezuelan populations) and forming wingbars appearing as two rows of elongated dots; outer edges of innermost remiges broadly cinnamon-buff to pale yellow; tail dusky olive; throat mottled greyish, merging with broad breastband of flammulated greyish-olive, darker breast streaks invading pale yellow of rest of underparts; thighs olive; iris medium greyish-brown; bill long, black; legs dark grey. Sexes alike. Juvenile undescribed. Race *albidiventer* is greyish-olive above, wingbars mainly pale yellow, underparts whitish to pale yellowish-white, breast and flanks flammulated with grey, lacking olive tinge. Voice. Emphatic, nagging-sounding two-part call, beginning with sharp note and ending with rapid, ascending trill, "skee-drrrrrrrt" or "peet-yeeer"; also a series of sneeze-like notes, "hit-chu, hit-chu".
Habitat. Middle storey to lower canopy of mid-elevation, humid montane forest and foothills, occasionally near forest edge, rarely in second growth. To 2400 m.
Food and Feeding. Arthropods; also small fruit and berries. Stomach contents in SE Peru contained 108 food items, of which lepidopteran larvae 25%, beetles (Coleoptera) 22%, orthopterans 22%, homopteran bugs (planthoppers) 9%, ants (Hymenoptera) 8%, spiders (Araneae) 7%, hemipterans 5%, other items 2%. Forages in rather open but shady perches under forest canopy; often joins mixed-species flocks in mid-storey. Sits erect, tail held straight down, pauses for 5-30 seconds to search mainly upwards; regularly lifts one wing momentarily high over back (rarely, both wings, or one followed by the other). Snatches insect prey with upward hover-gleans and upward strikes.
Breeding. Poorly documented; breeds in Mar in Costa Rica and Feb-Jul in Trinidad. Nest globular, with rounded side entrance shielded by a visor, made of fibrous rootlets, lined with silky seed down, suspended on rootlet beneath protective log or ledge, almost always in ravine and near stream, sometimes directly over rushing torrent. Clutch usually 2 eggs; no information in incubation and fledging periods.
Movements. Resident; may descend to slightly lower elevations during cold months.
Status and Conservation. Not globally threatened. Rare to locally common. Probably locally extinct wherever deforestation has been intense, e.g. in lowland forest in W Chiriquí (Panama). Occurs in many national parks and other protected areas throughout its range, e.g. Darién National Park, in Panama, Macarao and Paria Peninsula National Parks, in Venezuela, Tambito Nature Reserve, Río Claro Reserve and Tinigua National Park, in Colombia, Machalilla National Park and about five other reserves in Ecuador, Machu Picchu Historical Sanctuary and Northwest Peru Biosphere Reserve, in Peru, and Madidi National Park and Pilón Lajas Biosphere Reserve, in Bolivia.
Bibliography. Anon. (1998a), Bates & Zink (1994), Begazo (1995), Belcher & Smooker (1937), Blake (1962), Bond *et al.* (1989), Chapman (1917c, 1921, 1926), Cory & Hellmayr (1927), Cracraft (1985), Davies *et al.* (1994), Fitzpatrick (1980c, 1985b), Fjeldså & Krabbe (1990), Herklots (1961), Hilty (1997, 2003), Hilty & Brown (1986), Lanyon (1988b), Meyer de Schauensee (1982), Perry *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Salaman (1994), Schulenberg *et al.* (2001), Skutch (1967), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Temple (2002), Traylor (1977), Walker (2001), Wetmore (1972), White (2002), Williams & Tobias (1994), Zimmer (1941c).



118. Rufous-breasted Flycatcher

Leptopogon rufipectus

French: Pipromorphe à poitrine rousse **Spanish**: Orejero Pechirrufo
German: Rostbrust-Laubtyrann
Other common names: Rufous-breasted Leptopogon

On following pages: 119. Inca Flycatcher (*Leptopogon taczanowskii*); 120. Streak-necked Flycatcher (*Mionectes striaticollis*); 121. Olive-striped Flycatcher (*Mionectes olivaceus*); 122. Ochre-bellied Flycatcher (*Mionectes oleagineus*); 123. McConnell's Flycatcher (*Mionectes macconnelli*); 124. Grey-hooded Flycatcher (*Mionectes rufiventris*); 125. Northern Scrub-flycatcher (*Sublegatus arenarum*); 126. Amazonian Scrub-flycatcher (*Sublegatus obscurior*); 127. Southern Scrub-flycatcher (*Sublegatus modestus*); 128. Slender-billed Tyrannulet (*Inezia tenuirostris*); 129. Plain Tyrannulet (*Inezia inornata*); 130. Amazonian Tyrannulet (*Inezia subflava*); 131. Pale-tipped Tyrannulet (*Inezia caudata*).

Taxonomy. *Tyrannula rufipectus* Lafresnaye, 1846, Colombia [= "Bogota"].
Forms a superspecies with *L. taczanowskii*. Birds from extreme NE of range described as race *venezuelanus*, but indistinguishable from populations farther S along Colombian Andes. Monotypic.
Distribution. Locally in extreme SW Venezuela (Táchira), E & C Andes of Colombia (S Antioquia and Cundinamarca S to W Caquetá), E Andes of Ecuador and extreme N Peru (Cerro Chinguela, in Piura).

Descriptive notes. 13 cm; 13 g. Has crown slate-grey, lores and face mottled cinnamon rufous, rufous auricular patch bordered posteriorly by dusky crescent; upperparts dark olive; wings dusky, indistinct wingbars and edges of remiges buffy; tail warm buffy olive; throat and broad breastband bright cinnamon-rufous, rest of underparts yellow, thighs cinnamon-olive; iris dark brown; bill long, black; legs dark grey. Sexes alike, female on average slightly smaller than male. Juvenile not described. VOICE. Loud, abrupt squeaky "spik" given 1-5 times, usually at intervals of at least 1 minute.
Habitat. Humid upper montane wet forest, especially mossy cloudforest; occasionally ventures to forest edge and second growth. At 1500-2700 m; most common above 1900 m.
Food and Feeding. Arthropods; small fruits and berries may also be eaten. Inconspicuous; forages from shady perches in mid-storey and lower canopy; sits erect, tail straight down, searches mainly upwards. Often joins mixed-species flocks in forest mid-storey. Snatches insect prey with upward hover-gleans and upward strikes.
Breeding. Not documented.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Rare to locally fairly common. Fairly common at Hacienda La Providencia and near Bramón-Las Delicias pass, both in Venezuela, also at Finca Merenberg and Cueva de los Guácharos National Park, both in Colombia, in all national parks along E slope of Ecuador, and at Cerro Chinguela, in Peru. Probably locally extinct in areas where deforestation has been intense, e.g. in C Colombia.
Bibliography. Bates & Zink (1994), Chapman (1917c, 1926), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Miller (1963), Parker *et al.* (1985), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1977), Zimmer (1941c).

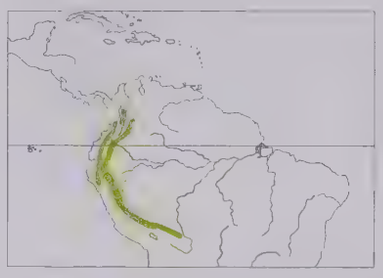
119. **Inca Flycatcher**

Leptopogon taczanowskii

French: Pipromorphe inca **German**: Graugesicht-Laubtyrann **Spanish**: Orejero Inca
Other common names: Inca Leptopogon

Taxonomy. *Leptopogon taczanowskii* Hellmayr, 1917, Ray-Urmana, Huayabamba Valley, 8000 feet [c. 2440 m], Amazonas, Peru.
Forms a superspecies with *L. rufipectus*. Present species originally named "*L. rufipectus*", but that name invalid, as preoccupied by its close relative. Monotypic.
Distribution. E Andes of Peru, from Amazonas and San Martín S to Cuzco.

Descriptive notes. 13 cm; 13 g. Plumage is olive above, crown darker brownish-olive; lores and face mottled whitish, whitish auricular patch bordered posteriorly by blackish facial crescent; wings dusky, outer webs of wing-coverts broadly tipped cinnamon (wingbars appearing as two rows of elongated dots), outer edges of innermost remiges broadly cinnamon-buff; tail warm dusky olive; throat greyish, merging with broad breastband of flammulated dark buffy olive, rest of underparts pale yellow, thighs olive; iris dark brown; bill long, black; legs dark grey. Sexes alike. Juvenile undescribed. VOICE. Sharp, excited "skwee" or "spik" given at irregular intervals or several times in succession.
Habitat. Humid upper montane forest, especially mossy cloudforest, occasionally venturing to edge or second growth. At 1400-2900 m; most common above 2000 m.
Food and Feeding. Arthropods; small fruits and berries may aso be eaten. Inconspicuous; forages from shady perches under forest canopy; sits erect, tail straight down, searches mainly upwards. Joins mixed-species flocks somewhat less often than do its congeners. Snatches prey with upward hover-gleans and upward strikes.
Breeding. Not documented.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in North-east Peruvian Cordilleras EBA. Uncommon to fairly common. Occurs in Río Abiseo and Yanachaga-Chemillén National Parks, Apurímac Reserved Zone, Alto Mayo Protected Forest and Machu Picchu Historical Sanctuary. Areas occupied by this species have been affected by widespread deforestation for cultivation, especially in Huallaga drainage, although cloudforests are relatively undisturbed.
Bibliography. Bates & Zink (1994), Chapman (1921), Cory & Hellmayr (1927), Cracraft (1985), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hornbuckle (1999), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Stotz *et al.* (1996), Terborgh (1971), Traylor (1977), Walker (2001), Zimmer (1941c).



Genus *MIONECTES* Cabanis, 1844

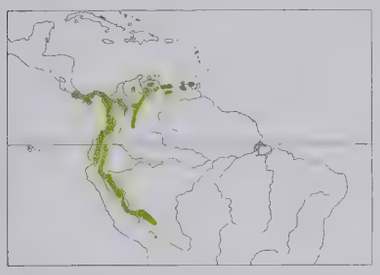
120. **Streak-necked Flycatcher**

Mionectes striaticollis

French: Pipromorphe strié **Spanish**: Mosquero Gorgiestriado
German: Graukappen-Pipratyrann

Taxonomy. *M[uscicapa] striaticollis* d'Orbigny and Lafresnaye, 1837, Yuracarés, Bolivia.
Closely related to *M. olivaceus*. Proposed race *poliocephalus* (Pasco and Junín, in C Peru) merged with nominate, as it occupies an indistinct zone of intergradation between subspecifically recognizable plumage patterns of N & S Peru; similarly, *selvae* (W Andes of Colombia) merged with *columbianus*, as these populations occupy a zone of diffuse intergradation between grey-crowned latter race and green-crowned *viridiceps*. Four subspecies recognized.
Subspecies and Distribution.
M. s. columbianus Chapman, 1919 - Andes of Colombia (except SW) S to E Ecuador.
M. s. viridiceps Chapman, 1924 - W Andean slopes from SW Colombia S to SW Ecuador.
M. s. palamblae Chapman, 1927 - Andes of N Peru from Piura, Cajamarca and San Martín S to Huánuco.
M. s. striaticollis (d'Orbigny & Lafresnaye, 1837) - S Peru (S from Cuzco and Madre de Dios) S to N Bolivia (La Paz, Cochabamba, N Santa Cruz).

Descriptive notes. 13·5 cm; 13-17 g. Nominate race is dark olive above, crown and nape slaty grey; face and auricular area dark grey, feather shafts white; tiny white spot behind eye; wings olive, occasionally indistinct faint buffish-olive wingbars; tail olive; throat and upper breast slate-grey, feather shafts narrowly to broadly white (producing distinct fine streaks), lower breast and flanks sharply streaked dark olive and yellow, centre of belly yellow, thighs olive; iris dark brown; bill long, dark brownish-grey, base of lower mandible pale pinkish; legs dark grey. Sexes alike. Juvenile resembles adult. Race *palamblae* differs from nominate in having olive suffusion throughout grey of crown and face, grey of throat restricted to chin area, finer white shaft streaks on face and throat, more restricted streaking on breast and flanks, hence more extensively yellow belly; *viridiceps* has crown dark olive, face and auricular area dark grey, throat and upper breast olive with fine white streaks; *columbianus* has dark olive-grey crown (more washed with olive in W Andes), greyish-olive face and auriculars, grey throat and upper breast finely streaked white. VOICE. Very quiet. Said to give thin, wiry notes during breeding season; also soft wing-whirring sound, presumably produced by very thin, attenuated ninth primary of male.
Habitat. Humid upper tropical and lower temperate montane forest, secondary forest; less often out to borders and adjacent clearings with isolated fruit-bearing trees. Mostly 1300-2500 m, locally down to 600-900 m; occasionally higher into temperate zone, recorded to 3400 m. Upper-elevational replacement of *M. olivaceus*.
Food and Feeding. Arthropods and berries. Usually solitary; sometimes joins mixed flocks or aggregations of tanagers (Thraupidae) and other birds at fruiting trees, but not a regular member of mixed-species flocks. Forages in forest understorey to subcanopy, usually in trees, but also in bushes, tangled thickets and dead shrubbery; perches upright, at times leaning forwards and bowing head, sometimes flicking single wing up over back. Hover-gleans among foliage, occasionally making short sallies for flying insects or to pick off a small fruit while hovering, returning to cover immediately after. Outside breeding season spends much time in picking berries in canopy.
Breeding. Males in breeding condition in Jan-Apr in Colombia and Sept-Dec in SE Peru; fledglings and juveniles in May and Jun in Colombia, Jan and Feb in NE Ecuador, Apr and May in Peru, and Mar, Aug and Dec in Bolivia; males singing Jan-May in Colombia and Jan in NE Ecuador. Partially lekking species, some males displaying solitarily; leks consist of 2-6 males on small territories 10-30 m across and within hearing range of one another (one in NE Ecuador had at least six birds in 0·5 ha), generally in primary or secondary forest, often near stream or river in tangled vines and dense undergrowth; male sings throughout morning from perches 1-6 m above ground, snapping head rapidly sideways with each song, bill swings sharply to side and upwards with each stroke, in synchrony with song units; uses many perches, singing on one for 30 seconds to 2 minutes, then making direct flight to new perch and singing immediately upon landing; lek-owner responds aggressively to intruders with active chase. Nest pendent, elongate, pyriform, with side entrance often slightly hooded, covered with moss, "tail" of plant fibres hanging loosely below, interior lined with soft seed down, dry moss and pale fibres, strands of hanging moss sometimes obscuring entrance; suspended from thin vine, rootlet or drooping twig 0·8-3 m above ground or small stream, often the vine or rootlet connected to more substantial substrate both above and below attachment point of nest; located inside tangle of vegetation or in more exposed site, in NE Ecuador all but one within 5 m of small stream inside intact mossy, epiphyte-laden forest with canopy height 15-25 m and characterized by thick understorey (one nest in highly disturbed forest, lacking canopy cover but covered by dense *Chusquea* bamboo averaging 3 m tall). Clutch size 2-3 eggs, laid one day apart; incubation daily coverage from 48% during first few days to 83%, incubation period (from last egg) 19 days; when approaching nest with eggs, female skulks low, well concealed in thick vegetation, until within several metres, then flies directly into nest, pausing only briefly on rim of entrance; eggs hatch synchronously; chick faecal sacs often bright purple-white, sometimes contain *Miconia* and *Myrica* seeds; nestling period at least 18 days.
Movements. Resident.
Status and Conservation. Not globally threatened. Considered generally common to locally uncommon. Occurs in all protected areas within its distributional limits. Not believed to be at any potential risk.
Bibliography. Butler (1979), Clements & Shany (2001), Cory & Hellmayr (1927), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Hornbuckle (2000), Meyer de Schauensee (1966, 1982), Miller (1963), Moynihan (1979), Remsen (1985), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Schulenberg *et al.* (2001), Sclater & Salvin (1879), Stotz *et al.* (1996), Walker (2001), Williams & Tobias (1994), Zimmer (1930, 1941c).



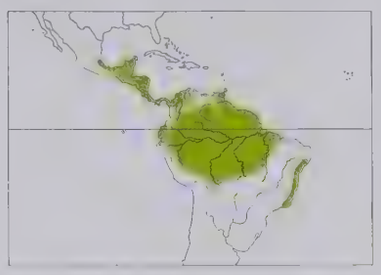
121. **Olive-striped Flycatcher**

Mionectes olivaceus

French: Pipromorphe olive **German**: Olivkopf-Pipratyrann **Spanish**: Mosquero Oliváceo

Taxonomy. *Mionectes olivaceus* Lawrence, 1868, Barranca, Costa Rica.
Closely related to *M. striaticollis*. Populations vary along two N-S clines, one from Costa Rica S to W Ecuador and the other following E base of mountains from NE Venezuela and Trinidad S to Bolivia; described race *improvisus* (N Cauca Valley) merged with *hederaceus*, as intermediate within W cline; *pallidus* (E Andes of Colombia in Magdalena and N Meta) and *meridae* (NW Venezuela and adjacent NE Colombia) are indistinct, intermediate forms within E cline, both treated as synonyms of *venezuelensis*. Five subspecies recognized.

Subspecies and Distribution.
M. o. olivaceus Lawrence, 1868 - E Costa Rica and W Panama.
M. o. hederaceus Bangs, 1910 - Panama (E from Veraguas), N & W Colombia (Cauca Valley, W slope and lowlands) and W Ecuador (S to Loja).
M. o. galbinus Bangs, 1902 - Santa Marta region of N Colombia.
M. o. venezuelensis Ridgway, 1906 - N Venezuela and S along E base of Andes to S Colombia; also Trinidad.
M. o. fasciaticollis Chapman, 1923 - E base of Andes from S Colombia S to S Peru and extreme N Bolivia.



Descriptive notes. 13·5 cm; 12 g. Nominate race has crown and nape, face and auricular area dark olive, feather shafts of face white, conspicuous white spot behind eye; upperparts warm yellow-green, wings and tail dusky olive; throat and upper breast densely streaked dark olive and yellowish-white, feather shafts narrowly to broadly white (distinct, fine streaks), lower breast and flanks sharply streaked dark olive and yellow, centre of belly yellow, thighs olive; iris dark brown; bill long, dark brownish-grey, base of lower mandible pale pinkish; legs dark grey. Sexes similar. Juvenile resembles adult. Race *hederaceus* has upperparts darker than nominate, throat streaks more pronounced whitish and dark greyish-olive, belly paler yellowish-white; *galbinus* has paler yellow-green upperparts, throat streaks very fine and bright yellow, entire underparts bright yellow; *venezuelensis* is slightly darker green above, even darker on crown, paler yellow below; *fasciaticollis* is uniform dark olive above, richer yellow below. Voice. Very quiet except in breeding season, when lekking male endlessly repeats a series of 3-4 very high, thin notes; sometimes delivered in small; loose groups.
Habitat. Lower and middle growth of humid forest, shady secondary woodland, and forest borders and plantations; most common in foothills and subtropical zone, especially preferring damp shady undergrowth in ravines, with heavy understorey growth. Mostly 500-1600 m, but recorded to 3000 m in Panama, Colombia and Venezuela, locally down to sea-level in NW South America; scarce below 600 m in E Ecuador, but common at 300 m in SE Peru. Mainly at lower elevations than *M. striaticollis*, but the two occur together at some sites, mostly between 1200 m and 1700 m.
Food and Feeding. Mainly frugivorous, known to eat fruits of *Trema*, *Heliconia*, *Urera*, and melastomes (Melastomataceae); arthropods also taken. Solitary, quiet, inconspicuous; forages in understorey, especially in densely vegetated areas under deep shade; perches for long periods upright, but often hunching and nodding head anxiously, and flicking one or both wings irregularly. Small berries in undergrowth taken by hover-gleaning under foliage or clinging momentarily to leaves; may forage also by hanging downwards from underside of a twig. Arthropods usually taken with upward hover-gleans.
Breeding. Eggs in Apr-May in Costa Rica; males in breeding condition in Apr and juveniles in Jul in Colombia; nests in Feb-Jun in Trinidad. In contrast to congeners, both sexes have been observed at nest-site, and this species may be monogamous: during breeding season, males appear to establish scattered individual singing territories in upper understorey. Nest pyriform, with side entrance, covered externally with green moss, round central chamber lined with soft pale brown fibres, suspended from free-hanging vine or aerial roots, often beside vertical cliff, bank or base of large tree, generally not more than 1-2 m above ground. Clutch 2-3 eggs; no information on incubation and fledging.
Movements. Descends to lowlands during non-breeding season in Costa Rica, probably also in Andes.
Status and Conservation. Not globally threatened. Fairly common to common, sometimes abundant; often the most common bird in mist-nets in Peruvian forested foothills at 350-500 m. Occurs in several national parks and other protected areas in all countries in its range.
Bibliography. Allen (1995), Anon. (1998a), Belcher & Smooker (1937), Blake (1958), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), ffrench (1991), Foster & Johnson (1974), Haffer (1975), Herklots (1961), Hilty (1997, 2003), Hilty & Brown (1986), Hornbuckle (2000), Meyer de Schauensee (1966, 1982), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Robinson & Terborgh (1997), Salaman (1994), Schulenberg *et al.* (2001), Sherry (1983), Slud (1960, 1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Temple (2002), Wetmore (1939, 1972), Williams & Tobias (1994), Zimmer (1930, 1941c).

122. Ochre-bellied Flycatcher
Mionectes oleagineus

French: Pipromorphe roussâtre **Spanish**: Mosquero Aceitunado
German: Ockerbauch-Pipratyrann
Other common names: Oleaginous Flycatcher/Pipromorpha

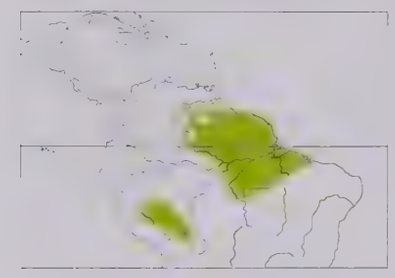
Taxonomy. *M[uscicapa] oleaginea* M. H. K. Lichtenstein, 1823, Bahia, Brazil.
Closely allied to *M. macconnelli* and *M. rufiventris*; the three were for long placed in a separate genus, *Pipromorpha*, on basis of specialized outer primaries of male, but they share numerous characters (including unusual lek breeding system) with both *M. striaticollis* and *M. olivaceus*. Races fall into two groups according to plumage, the "*assimilis* group" and the "nominate group". Variation within former sufficient to warrant retention of several names, but *obscurus* (El Salvador), *dyscolus* (W Costa Rica and extreme W Panama) and *lutescens* (W Panama, including Coiba I) merged with *assimilis*, because they represent barely discernible intermediate forms within a broad N-S cline. Geographical variation across widespread "nominate group" exceedingly minor, while individual, age-specific and sexual variation considerable; described races *intensus* (SE Venezuela and W Guyana), *wallacei* (the Guianas, NE & E Amazonian Brazil E of R Negro), *chloronotus* (Amazon Basin), *hauxwelli* (E Ecuador and NE Peru N of Amazon) and *maynanus* (EC Peru S to Pasco) all treated as synonyms of nominate. Seven subspecies recognized.
Subspecies and Distribution.
M. o. assimilis P. L. Sclater, 1859 - humid lowlands from S Mexico (Veracruz, Tabasco, Yucatán Peninsula) S to E Costa Rica and W Panama.
M. o. parcus Bangs, 1900 - E Panama (E from Canal Zone) E to N Colombia and NW Venezuela (Zulia, Táchira, Mérida).
M. o. abdominalis (Phelps, Sr & Phelps, Jr, 1955) - N Venezuela (Distrito Federal and Miranda E to Cerro Negro).
M. o. pacificus (Todd, 1921) - W of Andes in SW Colombia and W Ecuador.
M. o. pallidiventris Hellmayr, 1906 - NE Venezuela (Sucre and N Monagas S through Delta Amacuro), Trinidad and Tobago.
M. o. dorsalis (Phelps, Sr & Phelps, Jr, 1952) - Cerros Chimantá and Roraima, in S Venezuela.
M. o. oleagineus (M. H. K. Lichtenstein, 1823) - E Colombia, S Venezuela, the Guianas and all of Amazonia S to E Ecuador, E Peru and N Bolivia (Beni, Cochabamba), and in C & SE Brazil (from N Mato Grosso E to Maranhão and Bahia, and coastal region from Alagoas S to Rio de Janeiro).

Descriptive notes. 13 cm; 12-14 g. Nominate race is uniform olive, tinged ochraceous, above; wings and tail ochraceous olive, greater and median wing-coverts olive, indistinctly edged rufous-buff, innermost 3-4 remiges conspicuously edged rufous-buff; throat grey, entire underparts rich cinnamon-buff, upper breast variably suffused with ochraceous olive, grading into deep cinnamon-buff belly; iris dark brown; bill long, dark brownish-grey, base of lower mandible variable, from pale pinkish to dark brownish; legs dark grey. Sexes similar. Juvenile resembles adult. Race *pallidiventris* is slightly paler above and less ochraceous below than nominate; *dorsalis* has darker olive back and paler ochraceous belly; *assimilis* has wings and tail dusky olive, olive wing-coverts only faintly edged dull buffy rufous, innermost remiges only narrowly edged buffy, underparts more yellowish-buff, upper breast variably suffused with dark greyish-olive, grading into pale rusty buff belly; *parcus* has limited pale grey on throat, pale orangey-buff underparts; *pacificus* differs from last in brighter yellowish-green upperparts, buffy rump, even paler and more yellowish underparts; *abdominalis* has duller, pale buff-brown abdomen. Voice. Very quiet except during breeding season, when male on lek gives endless series of high, thin, wiry "pééor" notes while flying nervously and repeatedly from one perch to another.
Habitat. Lower growth of humid tropical lowland forest, second-growth woodland, gallery forest, and borders and adjacent clearings and gardens, often along forest streams, also plantations with scattered shade trees, sometimes several hundred metres beyond edge of neighbouring forest. Found in both *terra firme* and *várzea* forests, and in sandy-belt forests inside Amazonia. Less frequent inside primary forest and mostly restricted to second-growth and edge habitats in areas where sympatric with *M. macconnelli*. Most common in humid lowlands, but recorded up to 1800 m.
Food and Feeding. Largely frugivorous, but also consumes insects and arthropods. Berries of mistletoe (Loranthaceae) especially favoured; fruits of variety of other plants also eaten, including *Trema micrantha*, *Miconia myriantha*, *Protium heptaphyluum*, *Sloanea stipitata*, *Sapium aucuparium*, *Maprounea guianensis*, *Hieronyma caribaea* and *Cordia currassavica*, genera *Zanthoxylum*, *Alchornea*, *Siparuna*, *Farmea*, *Heliconia* and *Cephaelis*, and families Araliaceae, Araceae, Palmae, Melastomataceae, Euphorbiaceae, Ulmaceae, Guttiferae, Burseraceae, Tiliaceae, Boraginaceae. Unobtrusive and quiet, and generally solitary. Forages mostly in understorey and lower canopy, to 10 m above forest floor; occasionally accompanies mixed flocks to higher levels of forest. Makes short hover-gleans, and perch-gleans within foliage to pluck small insects, berries, small fruits, and arillate seeds; also drops to ground to pluck insects and spiders (Araneae) from fallen branches. Fruits swallowed whole; larger seeds regurgitated, small seeds pass through gut.
Breeding. Eggs in Jun in Honduras, Mar-Aug in Costa Rica and May-Jul in Trinidad and Tobago; birds in breeding condition in Feb-Jun in Colombia and Aug-Dec in SE Peru; males on lek territories in Mar-Jul in Costa Rica, Feb-Sept in Trinidad and Mar-Jun in Tobago. About 50% of males display in "exploded" leks, the rest display solitarily or act as floaters; leks mainly along ridge lines, under closed canopy, with few plants 1-3 m tall; 2-6 (mean 3) males at lek, generally 18-50 m apart (6 males within 0·5 ha in Costa Rica), each display territory c. 10-30 m in diameter; male uses many perches, usually 3-10 m off ground, sings persistently throughout day, flicking wings one at a time, ruffling crown feathers, flies from perch to perch, chases off intruders immediately; visiting females elicit increased calling rate and exaggeration of wing flicks, female also rapidly flicks wings; three displays by male, (1) hopping rapidly between different perches, (2) fluttering flight in steep arc between two perches, (3) hovering and fluttering 0·6-1 m above ground for nearly 1 minute in dense cover near low perch. Females nest asynchronously; nest built by female, pyriform, 30-36 cm long, 7·5 cm across at widest point, side entrance hole sometimes screened by projecting canopy or porch, entire nest camouflaged with mosses or liverworts, thread-like brown detritus up to 1 m long hanging from bottom, egg-chamber lined with long strands of black material resembling horsehair (possibly rhizomes); nest suspended from aerial root or vine or from side of bank or tree trunk, usually no more than 4 m above ground, often over stream, also in undercut side of quarry or on underside of heavy fallen log. Clutch 2-5 eggs, usually 3, laid at 2-day intervals; incubation by female, period 18-21 days; chicks fed by female, by regurgitation, nestling period not documented. Breeding success low, only 12% of nests started produce fledged young.
Movements. Resident; local densities vary seasonally, probably according to fruit abundance. In one study, females moved on average 1855 m during day, and single movements of up to 1400 m observed; two types of movement bouts described, slow, exploratory movements associated with foraging, and longer, directional shifts.
Status and Conservation. Not globally threatened. Uncommon to common, locally abundant. Occurs in numerous national parks and other protected areas throughout its range. Average home range of female 28 ha in one study. Reasonably adaptable species, found in secondary and disturbed habitats as well as in pristine forest.
Bibliography. Anon. (1998a), Belcher & Smooker (1937), Binford (1989), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), ffrench (1991), Haffer (1975), Haverschmidt (1968), Haverschmidt & Mees (1994), Henderson (2002), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Lee Jones (2004), Meyer de Schauensee (1966, 1982), Moermond & Denslow (1985), Monroe (1968), Munn (1985), Olson (1997), Payne (1984), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Robinson & Terborgh (1997), Salaman (1994), Sclater & Salvin (1879), Sherry (1983), Sick (1993, 1997), Skutch (1960, 1976, 1985), Slud (1964), Snow & Snow (1979), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Thurber *et al.* (1987), Tostain *et al.* (1992), Westcott (1992, 1993, 1994, 1997a, 1997b), Westcott & Graham (2000), Westcott & Smith (1994, 1997), Wetmore (1972), White (2002), Wiedenfeld *et al.* (1985), Willis (1980), Willis *et al.* (1978), Wright *et al.* (1985), Zimmer (1941c).

123. McConnell's Flycatcher
Mionectes macconnelli

French: Pipromorphe de McConnell **Spanish**: Mosquero de McConnell
German: Schwarzschnabel-Pipratyrann

Taxonomy. *Pipromorpha oleaginea macconnelli* Chubb, 1919, Kamakabra River, Guyana.
Scientific name was incorrectly formed, as species is named after F. V. McConnell. Closely related to *M. oleagineus* and *M. rufiventris*; all three were for long placed in a separate genus, *Pipromorpha*,



on basis of specialized outer primaries of male, but they share numerous characters (including unusual lek breeding system) with both *M. striaticollis* and *M. olivaceus*. Large series of specimens (including fresh ones) now available from across Amazon Basin S to Bolivia reveal remarkably little geographical variation over such a vast area, especially in comparison with distinctly different C Peruvian *peruanus*; described race *amazonus*, from C Brazil and E Bolivia, considered better treated as synonymous with nominate. Birds from Cerro de la Neblina (S Venezuela) named as race *mercedesfosterae*, but characters fall within range of variation of *roraimae*, thus merged with latter. Three subspecies recognized.

Subspecies and Distribution.

M. m. macconnelli (Chubb, 1919) - lowland tropics of E Venezuela (NE Bolívar), the Guianas and lower Amazonian Brazil (E from R Negro and R Madeira, possibly from Amazonas, S to N Mato Grosso and C Pará). SE Peru (S Ucayali, Madre de Dios; also sight record from R Javari, in NE) and NE Bolivia (Pando, Beni, La Paz, Cochabamba, Santa Cruz).

M. m. roraimae (Chubb, 1919) - tepui region of S & SE Venezuela and Guyana.

M. m. peruanus (Carriker, 1930) - C Peru (Junín).

Descriptive notes. 13·5 cm; 13-14 g. Nominate race is uniform olive above; wings and tail entirely dusky olive; rich cinnamon-buff below, throat and upper breast suffused with dark greyish-olive; iris dark brown; bill long, dark brownish-grey, base of lower mandible pale pinkish, mouth-lining black; legs medium brownish-grey. Distinguished from extremely similar *M. oleagineus* mainly by lack of buffy tips on tertials. Sexes similar. Juvenile resembles adult. Races differ mainly in degree of ochraceous tinge throughout: *roraimae* is brighter greenish-olive above, but darker cinnamon below; *peruanus* is much brighter olive and tinged ochraceous above, greater wing-coverts edged cinnamon, paler and brighter buffy orange below, chin and upper throat lightly tinged olive. Voice. Displaying male gives widely spaced or repeated series of nasal "wiib" notes, often in long succession.

Habitat. Lower growth of humid forest, primarily *terra firme*, but also in forest plantations, second growth, and river-flooded or tide-flooded *várzea* forest (e.g. at Belém, in Brazil). Mostly below 500 m, but mainly 1000-2000 m in Venezuela, and recorded to 2400 m in Bolivia.

Food and Feeding. Arthropods; also feeds extensively on understorey fruits (e.g. Rubiaceae, Melastomataceae). Regularly joins mixed flocks of small insectivores in understorey, but not an obligate mixed-flock species. Forages 1-25 m above forest floor; perches inconspicuously in shaded areas; makes short hover-gleans in foliage.

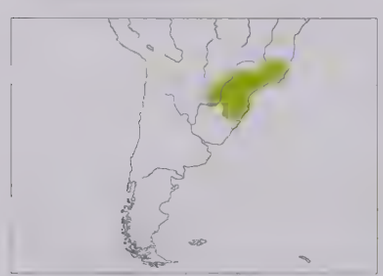
Breeding. Eggs in Jan-Mar in N Brazil, and birds in breeding condition in Sept-Nov in SE Peru. Sings and displays 1-2 m above ground, often near base of buttressed tree, sometimes while foraging with flocks near display grounds; small, dispersed leks roughly 50 m wide, on gentle slopes near forest creeks, individual callers separated by 50-100 m or more; displays include fluttering short flights and hovering, also periodically flashing out one wing or the other. Nest a leafy or strand ball with side entrance, variable in materials and appearance, short entrance tunnel inclines up to central nest cup of soft material; suspended on vine or at tip of twig 1-1·5 m above pool or small forest stream. Clutch 3 eggs, laid 2 days apart; incubation c. 19 days; chick growth rate slow, weight gain from 1·5 g at hatching to 12-13 g takes 10 days, fledging occurs 17-20 days after hatching of last young. Adults make no attempt to protect nest.

Movements. Apparently resident, although mist-net capture frequencies vary seasonally in SE Peru.

Status and Conservation. Not globally threatened. Uncommon to locally common. Nesting density unusually high, occupied nests may be only 100-200 m apart along small creeks. Occurs in many national parks and other protected areas throughout its range, e.g. Jaú and Tapajós National Parks and Ducke Reserve, in Brazil, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, and Beni and Pilón Lajas Biosphere Reserves and Madidi National Park, in Bolivia. Much of this species' habitat remains in good condition.

Bibliography. Allen (1995), Angehr & Aucca (1997), Blake (1950), Chapman (1931), Chubb (1919), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Cracraft (1985), Dickerman & Phelps (1987), Fjeldså & Krabbe (1990), Gilliard (1941), Green (1998), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Mayr & Phelps (1967), Meyer de Schauensee (1966, 1982), Naka (2004), Oren & Parker (1997), Payne (1984), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992), Traylor (1977), Willard *et al.* (1991), Willis *et al.* (1978), Zimmer (1941c).

124. Grey-hooded Flycatcher



Mionectes rufiventris

French: Pipromorphe à ventre roux **Spanish**: Mosquero Ladrillito
German: Graukopf-Pipratyrann

Taxonomy. *Mionectes rufiventris* Cabanis, 1846, Brazil.

Closely allied to *M. oleagineus* and *M. macconnelli*; the three were for long placed in a separate genus, *Pipromorpha*, on basis of specialized outer primaries of male, but they share numerous characters (including unusual lek breeding system) with both *M. striaticollis* and *M. olivaceus*. Monotypic.

Distribution. SE Brazil (S Minas Gerais and Espírito Santo S to Rio Grande do Sul), SE Paraguay and NE Argentina (Misiones).

Descriptive notes. 13·5 cm; 14 g. Has crown, nape and entire face uniform slate-grey, upperparts dark olive, wings and tail entirely dusky olive; chin and throat pale grey (completing the grey "hood"), grading through buffy olive on lower breast to bright cinnamon-buff on belly, flanks and undertail-coverts; iris dark brown, bill long, dark brownish-grey, base of lower mandible pale pinkish; legs medium brownish-grey. Sexes alike. Juvenile undescribed. Voice. Displaying male gives series of odd, low nasal "bayo" notes resembling those of antshrikes (*Thamnophilus*), starting slowly, then accelerating before abruptly stopping; a second type of vocalization consists of a series of "wiib" notes, similar to alarm calls of Pale-breasted Thrush (*Turdus leucomelas*). Calls usually given from perch 3-8 m above ground.

Habitat. Lower growth of humid forest, also secondary woodland and borders; sea-level to c. 1000 m.

Food and Feeding. Insects and fruit. Forages in shady understorey of forest; perches for long periods, bobs head; often flicks one or both wings in agitated manner, as if wanting to lift them. Most food items obtained by hover-gleaning; occasionally sallies out to capture aerial insects.

Breeding. Eggs in Feb in S Brazil and Sept-Oct in Argentina; birds in breeding condition in Dec and males singing on territories at end of Aug-Jan dry season in SE Brazil. Some males sing in dispersed leks of two or three individuals, 33% display solitarily; singing persists until late morning from perches 2-4 m above forest floor, separated by 30 m from other males; displays most active in morning, decreasing in afternoon; intruding non-territorial males (more common on less active lek sites) either chased by territory-owner, or latter gives "tail-cocked" display in which he approaches intruder, faces in opposite direction and raises tail (exposing ochraceous undertail-coverts) while simultaneously dropping wings and vibrating them rapidly, then follows intruder through understorey, whole display lasting for less then 1 minute; another display is 30-second series of jumps 20-30 cm high, accompanied by wing-flicking, sometimes with hovering, returning to same position on horizontal twig 1 m above ground. Nest an elaborate elongate, pyriform structure, side entrance with small projecting roof, almost entirely covered with living moss, rounded nest-chamber lined with blackish fibres and covered by layer of soft straw, attached to pendant vine with fungal rhizomes, c. 2 m up and usually hanging over small stream; one record of abandoned nest of *Leptopogon amaurocephalus* being used. Clutch usually 3 eggs; no information on incubation and fledging periods.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to fairly common. Especially common around Iguazú Falls, on Argentina-SE Brazil border. Occurs in various protected areas, including at least seven national parks, throughout range.

Bibliography. Aguilar *et al.* (2000), Belton (1985), Bencke (1995), Brooks *et al.* (1993), Canevari *et al.* (1991), Castelino & Saibene (1989), Chapman (1917c, 1926), Cory & Hellmayr (1927), Cracraft (1985), Guerra & Marini (2002), Guix (1995), Hayes (1995), Lowen *et al.* (1996), Meyer de Schauensee (1966, 1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Oniki & Willis (1983b), de la Peña (1979, 1988), Pizo & Aleixo (1998), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Venturini *et al.* (2001).

Genus *SUBLEGATUS* P. L. Sclater & Salvin, 1868

125. Northern Scrub-flycatcher

Sublegatus arenarum

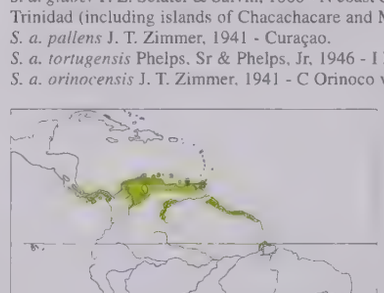
French: Tyranneau des palétuviers **Spanish**: Mosquero Matorralero Norteño
German: Nördlicher Strauchtyrann
Other common names: Smooth Scrub-flycatcher (South American races combined)

Taxonomy. *Elainea* [sic] *arenarum* Salvin, 1863, Punta Arenas, Costa Rica.

Unpublished molecular data suggest that genus is closely related to *Suiriri islerorum*. All members of genus formerly treated as conspecific, but vocal and plumage data support existence of three species, possibly more; additional study needed in order to resolve species limits. Nominate race (perhaps with *atrirostris*) possibly a separate species from others. Race *tortugensis* doubtfully distinct from *pallens*. Six subspecies recognized.

Subspecies and Distribution.

S. a. arenarum (Salvin, 1863) - Costa Rica and W Panama.



S. a. atrirostris (Lawrence, 1871) - Pearl Is (off S Panama) and N Colombia.

S. a. glaber P. L. Sclater & Salvin, 1868 - N coast of Venezuela (including Margarita I and Patos I), Trinidad (including islands of Chacachacare and Monos) and N parts of the Guianas.

S. a. pallens J. T. Zimmer, 1941 - Curaçao.

S. a. tortugensis Phelps, Sr & Phelps, Jr, 1946 - I La Tortuga, off N Venezuela.

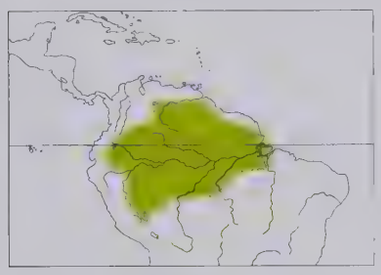
S. a. orinocensis J. T. Zimmer, 1941 - C Orinoco valley in S Venezuela and E Colombia.

Descriptive notes. 13-15 cm; 10·5-15 g. Nominate race has narrow whitish supercilium, greyish-brown crown and upperparts; wings dusky grey, paler greyish to whitish wingbars and flight-feather edges; tail dusky, tips of fresh rectrices whitish; chin whitish, throat and chest pale grey, abdomen medium yellow; iris dark brown; bill short, stubby, black; legs grey. Separated from congeners by comparatively longer bill, pale grey breast sharply demarcated from bright yellow belly and abdomen. Sexes alike, female on average smaller than male. Juvenile resembles adult. Races differ only very slightly: *glaber* is larger than nominate, darker olive-brown above, crown feathers somewhat elongated and slightly darker than back, wingbars duller; *atrirostris* differs from previous in paler, more grey-brown upperparts, more conspicuous white wingbars, duller white throat, paler grey breast and flanks; *pallens* is similar to last but even paler, more grey above, throat and breast whiter, also slightly smaller; *tortugensis* is even whiter on throat and possibly smaller than previous; *orinocensis* is palest and smallest, with more sharply defined pale wingbars and edges of remiges. Voice. Dawn song a loud, repeated "pfweéé"; also widely spaced "phew!-dit" shortly after dawn; contact call a squeaky "peee" (as produced by squeezing a rubber toy), often given in couplets with mate.

Habitat. Mangroves and adjacent vegetation, including scrubby second growth. In N Venezuela (*glaber*) found in mangroves, open dry scrub, cactus and thorn woodlands, and desert areas; *atrirostris* and *orinocensis* mainly in scrubby second growth and dry woodland. Sea-level to 600 m.

Food and Feeding. Food arthropods, including ants (Hymentoptera), caterpillars (Lepidoptera), small beetles (Coleoptera); small berries also frequently taken. Forages inconspicuously in shrubs and small trees, perching upright with tail vertically downwards; makes long pauses and peering head movements; food items obtained by outward hover-gleans to vegetation and short aerial sallies.

Breeding. Mar-Jun; stub-tailed young in Aug, Colombia. Nest a simple cup, 7·5 cm × 4 cm, placed 2-6 m up in fork of small tree. Clutch 2 eggs; incubation period at least 14 days, female fed on nest by male; no information on nestling period.



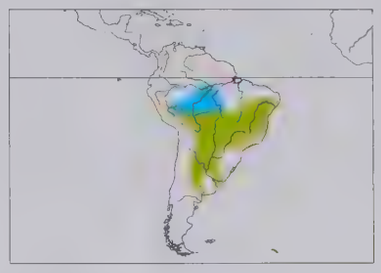
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. In Panama, most abundant near coast and fairly common on several islands and in the Tocumen area; especially common in Salamanca National Park, in Colombia, and occurs also in Carara Biological Reserve, in Costa Rica. Populations inhabiting second growth and open, dry woodland may presumably benefit from degradation of primary forest; those in mangroves more at risk as a result of widespread destruction of this habitat.
Bibliography. Anon. (1998a), Bond *et al.* (1989), Chapman (1894), Cherrie (1916), Cory & Hellmayr (1927), ffrench (1991), Fitzpatrick (1980c), Friedmann (1948), Friedmann & Smith (1950), Haverschmidt (1968), Haverschmidt & Mees (1994), Hayes & Samad (2002), Herklots (1961), Hilty (2003), Hilty & Brown (1986), LeCroy (1976), Olson (1997), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Slud (1964, 1980), Snyder (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Temple (2002), Tostain *et al.* (1992), Traylor (1982), Voous (1983), Wetmore (1939, 1946, 1972), Wright *et al.* (1985), Zimmer (1941b).

126. **Amazonian Scrub-flycatcher**

Sublegatus obscurior

French: Tyranneau ombré **Spanish**: Mosquero Matorralero Amazónico
German: Amazonas-Strauchtyrann
Other common names: Dusky Flycatcher, Todd's Scrub-flycatcher

Taxonomy. *Sublegatus glaber obscurior* Todd, 1920, Cayenne, French Guiana.
Unpublished molecular data suggest that genus is closely related to *Suiriri islerorum*. All members of genus formerly treated as conspecific, but vocal and plumage data support existence of three species, possibly more; additional study needed in order to resolve species limits. Monotypic.
Distribution. Amazonia from E Colombia, S Venezuela and S Guianas S to E Ecuador, E Peru, NW Bolivia and NC Brazil (S, in E, to R Tocantins, in Pará).



Descriptive notes. 14 cm; 14·5-17 g. Has faint, thin pale supercilium; dark greyish-brown above, wings dusky grey with indistinct greyish to whitish wingbars; tail dusky; chin, throat and upper breast dark, dusky grey, abdomen dingy yellow; iris dark brown; bill short, stubby, black; legs grey. Distinguished from congeners by darker plumage overall, darker grey of throat grading into duller yellow underparts, lacking sharp demarcation between breast and belly. Sexes alike. Juvenile not described. Voice. Dawn song a loud, repeated phrase of 2-3 syllables, "ch-we-deé ch-we-deé chu-weeé", third syllable upslurred and not always given during each bout; call note "jeeer", more burry and drawn out than that of *S. modestus*, lacking squeaky quality of *S. arenarum* call.
Habitat. Scrubby clearings and forest and river edge, from sea-level to at least 450 m; locally to 900 m at base of E Andes. Typically in more mesic habitats than those preferred by congeners.
Food and Feeding. Arthropods; probably also small berries. Forages inconspicuously in shrubs and small trees, perching upright with tail vertically downwards; makes long pauses and peering head movements; food items obtained by outward hover-gleans to vegetation and short aerial sallies.
Breeding. Enlarged testes and song during Jul, and nest-building in late Jul, in Ecuador; enlarged testes during Mar in Guyana. Nest is open cup in fork of horizontal branch, c. 8 m above ground. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Local and apparently rare to uncommon, although easily overlooked because of inconspicuous behaviour. Occurs in La Selva Lodge, in Ecuador, Tambopata-Candamo Reserved Zone, in Peru, and Madidi National Park, in Bolivia. Has probbly increased, and will continue to do so, with degradation of primary forest; elevational range may increase with degradation at base of E Andes.
Bibliography. Allen (1995), Cory & Hellmayr (1927), Greeney *et al.* (2004), Hennessey, Herzog & Sagot (2003), Hilty (2003), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1982), Zimmer (1941b).

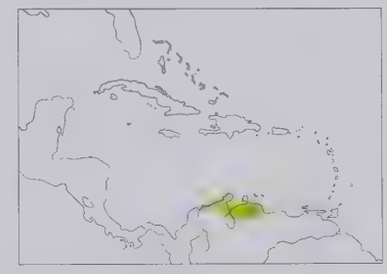
127. **Southern Scrub-flycatcher**

Sublegatus modestus

French: Tyranneau modeste **Spanish**: Mosquero Matorralero Sureño
German: Südlicher Strauchtyrann

Taxonomy. *M(uscipeta) modesta* Wied, 1831, Camamú and Bahia, Brazil.
Unpublished molecular data suggest that genus is closely related to *Suiriri islerorum*. All members of genus formerly treated as conspecific, but vocal and plumage data support existence of three species, possibly more; additional study needed in order to resolve species limits. Birds in highlands of Bolivia, which are longer-winged but resident, may represent an unnamed cryptic species. Two subspecies recognized.
Subspecies and Distribution.
S. m. modestus (Wied, 1831) - C Peru (Urubamba Valley) and N Bolivia E through S Brazil (E to Maranhão, Pernambuco and Paraná).
S. m. brevirostris (d'Orbigny & Lafresnaye, 1837) - breeds S Bolivia and Paraguay S to N Argentina (S to Buenos Aires and Mendoza) and E to Uruguay; regular non-breeding visitor N to E Peru and C Amazonia.
Descriptive notes. 13 cm; 9·5-13 g. Nominate race is greyish-brown above, with almost imperceptible pale supercilium; wings dusky grey, with paler greyish wingbars; tail dusky; chin whitish, throat and chest pale grey, grading into medium to pale yellow abdomen; iris dark brown; bill very short and stubby, black; legs grey. Separated from congeners by smaller size, especially smaller bill. Sexes alike. Juvenile undescribed. Race *brevirostris* has longer wings and tail, pure white wingbars. Voice. Dawn song of lowland birds a loud, repeated 2-syllable "pseee-ú"; call note a soft "cheer".
Habitat. Breeds in arid scrub and open deciduous woodland, mainly in very dry habitats; during migration and on wintering grounds in N Bolivia, recorded to 2750 m.
Food and Feeding. Arthropods recorded. Forages inconspicuously in shrubs and small trees, perching upright with tail vertically downwards; food items obtained by outward hover-gleans to vegetation and short aerial sallies.

Breeding. Nest-building in Sept and many nests with eggs or young Oct-Dec in Argentina; singing and birds with enlarged testes in late Oct in N Paraguay. Nest a small cup, 4 cm × 1 cm, placed 1-2 m up in fork of small bush or tree. Clutch 2 eggs; incubation period 17 days and nestling period 14-16 days (Argentina).
Movements. Migratory in S. Populations breeding in Argentina (*brevirostris*) reach N at least to W Amazonia, and recorded as far N as Mitú, in SE Colombia; perhaps regular migrant to N of Amazon, but typically overlooked because of highly inconspicuous behaviour and plumage.
Status and Conservation. Not globally threatened. Uncommon. Occurs in several protected areas, e.g. Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Noel Kempff Mercado National Park, in Bolivia, and Serra da Canastra National Park, in Brazil. Populations in second growth and open, dry woodland may presumably benefit from degradation of primary forest.
Bibliography. Allen (1995), Bates & Parker (1998), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Di Giacomo (2004), Dubs (1992), Hayes (1995), Hilty & Brown (1986), Joseph (1996), Meyer de Schauensee (1982), Mezquida (2002), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (1983), Olivares (1964), de la Peña (1987, 1988, 1995), Ridgely & Tudor (1994), Short (1975), da Silva *et al.* (1997), Stotz *et al.* (1996), Traylor (1982), Zimmer (1941b).



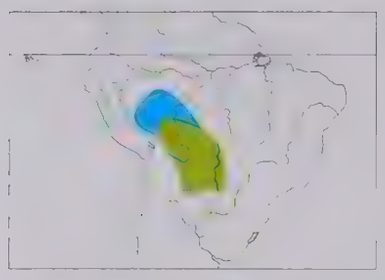
Genus *INEZIA* Cherrie, 1909

128. **Slender-billed Tyrannulet**

Inezia tenuirostris

French: Tyranneau à bec fin **German**: Olivbraun-Tachurityrann **Spanish**: Piojito Picofino

Taxonomy. *Camptostoma pusillum tenuirostris* Cory, 1913, River Aurare, Venezuela.
Genus as currently constituted is probably polyphyletic. Present species perhaps merits monotypic genus, or its relationships lie elsewhere in family. Monotypic.
Distribution. Desert regions of extreme NE Colombia (including Santa Marta region) and NW Venezuela.



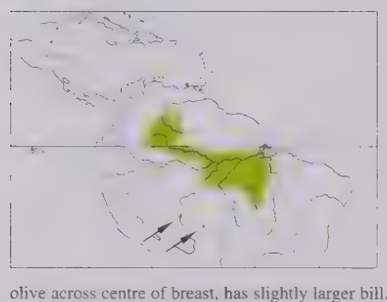
Descriptive notes. 9 cm; 5-6 g. Tiny, nondescript desert tyrannulet with needle-like bill. Has narrow eyering and narrow supercilium white; crown and upperparts greyish-olive, wings dusky, two thin wingbars and outer edges of inner remiges dull white; tail dusky olive, feathers with pale outer edges and tips; face and throat whitish, breast and belly dingy greyish white, tinged pale yellow on belly and undertail-coverts; iris dark brown; bill short and thin, black; legs grey. Sexes alike. Juvenile undescribed. Voice. Long, dry trill trailing off and fading at end; also whistled "teer-téér-teer-terr-teer".
Habitat. Dry thorn-scrub, arid woodlands, tall *Acacia*-dominated arroyos, cactus desert with tall shrubs, cattle pastures with tall thorny shrubs, shrubby gardens surrounded by desert; also mangrove edges. Sea-level to 300 m, locally to 800 m.
Food and Feeding. Insects; also berries and small fruits. Usually alone or in pairs, rarely joins mixed-species flocks. Forages actively at all levels in dense shrubs, often cocks tail slightly; perch-gleans and hover-gleans in foliage and twigs, behaviour like that of a vireo (Vireonidae).
Breeding. Not documented.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Caribbean Colombia and Venezuela EBA. Fairly common to common. Common in lowland scrub W of Santa Marta Mts and on Guajira Peninsula, in Colombia; especially common throughout Falcón and on Paraguaná Peninsula, in Venezuela. Although large expanses of suitable habitat remain within the species' limited range, none is protected; moreover, substantial areas have been destroyed, principally around L Maracaibo (Venezuela), as a result of overgrazing, firewood-gathering, tourist development and environmental pollution.
Bibliography. Cory & Hellmayr (1927), Cracraft (1985), Fitzpatrick (1980c, 1985b), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Ridgway (1907), Stotz *et al.* (1996), Strewe & Navarro (2003), Zimmer, J.T. (1955b), Zimmer, K.J. & Whittaker (2000).

129. **Plain Tyrannulet**

Inezia inornata

French: Tyranneau terne **German**: Grauscheitel-Tachurityrann **Spanish**: Piojito Picudo

Taxonomy. *Serpophaga inornata* Salvadori, 1897, San Francisco, Tarija, Bolivia.
Genus as currently constituted is probably polyphyletic. Present species was for long placed in genus *Serpophaga*, and has been proposed that the two genera be merged; syringeal evidence, however, suggests that *Inezia* is closer to *Sublegatus*. Monotypic.
Distribution. SE Peru (Madre de Dios), N & E Bolivia, adjacent SW Brazil (N to Rondônia), N Paraguay, and NW Argentina (Salta, Jujuy). Breeding range uncertain, probably only non-breeding visitor in Peru, N Bolivia and Brazil; specimen dates indicate possible breeding as far N as Beni (Bolivia).
Descriptive notes. 10 cm; 5·5-6 g. Has thin whitish supercilium, and greyish to olive-grey crown and upperparts; wings dusky, with two thin wingbars and outer edges of inner remiges dull white; tail dusky; face, chin and throat whitish, underparts dingy grey, tinged pale yellowish on lower



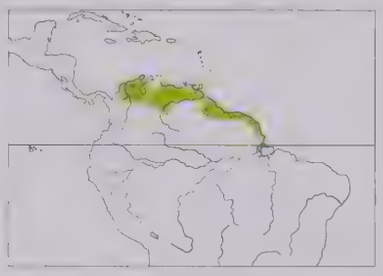
abdomen; iris dark brown; bill thin, black, with base of lower mandible sometimes pale; legs grey. Sexes alike. Juvenile not described.
Voice. A somewhat musical series of thin whistles with emphatic introductory note, "psee-tee-ee-ee-ee".
Habitat. Inhabits deciduous and semi-deciduous woodland, Chaco, and forest borders; in non-breeding season, mainly shrubby river margins and *Tessaria*-dominated early-successional growth bordering beaches. Sea-level to 700 m.
Food and Feeding. Insects; probably some fruit. Usually alone or in pairs; occasionally joins mixed-species flocks. Forages actively in dense foliage, often cocks tail slightly; mainly perch-gleans, also hover-gleans in foliage and twigs.
Breeding. Birds with enlarged gonads in Nov in Bolivia. No other information.
Movements. Apparently present in Peru, Brazil and N Bolivia (N of 17° S) only in austral winter, suggesting migration from breeding grounds in Argentina, Paraguay and E Bolivia.
Status and Conservation. Not globally threatened. Status not well known; apparently uncommon. Has been recorded in Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Madidi and Noel Kempff Mercado National Parks and Beni Biosphere Reserve, in Bolivia, and San Luis National Park, in Paraguay.
Bibliography. Allen (1995), Bates & Parker (1998), Canevari *et al.* (1991), Chesser (1997), Cory & Hellmayr (1927), Dubs (1992), Fitzpatrick (1980c, 1985b), Hayes (1995), Joseph (1996), Lanyon (1988b), Meyer de Schauensee (1982), Miserendino (1998), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Parkes (1973), de la Peña (1988), Perry *et al.* (1997), Ridgely & Tudor (1994), Ridgway (1907), Short (1975), Sick (1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Wetmore (1926), Willis & Oniki (1990), Zimmer (1955), Zyskowski *et al.* (2003).

130. Amazonian Tyrannulet

Inezia subflava

French: Tyranneau givré **German**: Braunscheitel-Tachurityrann **Spanish**: Piojito Pantanero

Taxonomy. *Serpophaga subflava* P. L. Sclater and Salvin 1873, Belém, Pará, Brazil.
Genus as currently constituted is probably polyphyletic. Present species and *I. caudata* closely related and formerly considered conspecific; recently split on basis of differences in plumage, iris colour and, especially, vocal behaviour. Two subspecies recognized.
Subspecies and Distribution.
I. s. obscura J. T. Zimmer, 1939 - S Venezuela (Amazonas), adjacent SE Colombia (E Guainía, E Vaupés) and NW Brazil (vicinity of upper R Negro).
I. s. subflava (P. L. Sclater & Salvin, 1873) - EC Brazil (lower R Negro and lower R Madeira E to Pará) and extreme N Bolivia (Beni, NE Santa Cruz); probably also in intervening region of Amazon Basin.



Descriptive notes. 12 cm; 7-8 g. Nominate race has broad white eyering and supraloral area extending forwards to above nostrils (prominent "spectacles"); crown and upperparts olive-brown, wings dusky, two thin wingbars and outer edges of inner remiges dull white to pale yellowish-white; tail quite long, dusky olive, conspicuously whitish to pale ochraceous on outer edges and tips; face and chin whitish, throat and underparts yellow, tinged or flammulated olive on side of breast; iris brown; bill long and thin, black; legs grey. Sexes alike, female slightly smaller than male. Juvenile undescribed. Race *obscura* is strongly washed olive across centre of breast, has slightly larger bill.
Voice. Main song a dry rattle of closely spaced notes (26 notes in 2 seconds), on one pitch; also distinctive duet, with explosive series of "pit-chew" notes (2 per second) probably by male, and slightly lower-pitched "kut-up" or "kutterup" notes at slightly faster intervals probably by female, duets sometimes initiated by rapid series of "kip" notes by presumed male; also an abrupt, loud series of "chew" notes, and abrupt "pik".
Habitat. Shrubby vegetation along streamsides and riverbanks, dense swamp-forest, *várzea*; usually near water. Sea-level to 200 m.
Food and Feeding. Insects recorded. Forages actively, in pairs, usually 1-3 m above ground in dense shrubs, tail almost always held cocked above horizontal; perch-gleans and hover-gleans items from foliage.
Breeding. Nest (Brazil) a simple cup. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Common at Puerto Inírida (NE Guainía), in Colombia. Occurs in Jaú and Tapajós National Parks and Anavilhanas Zoological Station, in Brazil, and Noel Kempff Mercado National Park, in Bolivia.
Bibliography. Anon. (2001g), Bates & Parker (1998), Cory & Hellmayr (1927), Friedmann (1948), Green (2001a), Hennessey, Herzog & Sagot (2003), Hilty (2003), Hilty & Brown (1986), Lanyon (1988b), Meyer de Schauensee (1982), Oren & Parker (1997), Ridgely & Tudor (1994), Ridgway (1907), Sick (1993, 1997), Snethlage (1935), Stotz *et al.* (1996), Traylor (1977), Zimmer & Whittaker (2000).

131. Pale-tipped Tyrannulet

Inezia caudata

French: Tyranneau frangé **German**: Blassspitzen-Tachurityrann **Spanish**: Piojito Coludo

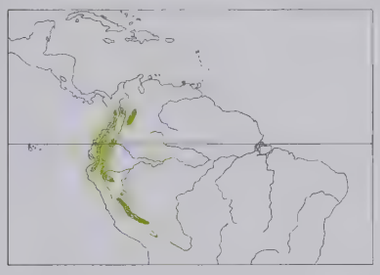
Taxonomy. *Capsiempis caudata* Salvin, 1897, Ourumee, Guyana.
Genus as currently constituted is probably polyphyletic. Present species and *I. subflava* closely related and formerly considered conspecific; recently split on basis of differences in plumage, iris colour and, especially, vocal behaviour. Two subspecies recognized.
Subspecies and Distribution.
I. c. intermedia Cory, 1913 - NE Colombia (lower Magdalena Valley, Santa Marta region) and N Venezuela (Maracaibo Basin, and Portuguesa E to Sucre).
I. c. caudata (Salvin, 1897) - C & E Venezuela (from Apure, lower R Caura, R Orinoco and Delta Amacuro) E through the Guianas, and N Brazil (R Branco region and Amapá).

Descriptive notes. 12 cm; 7-8 g. Nominate race has broad white eyering and supraloral line extending forwards to above nostrils (prominent "spectacles"); crown and upperparts olive-brown to greyish-brown, crown noticeably more grey; wings dusky, two thin wingbars and outer edges of inner remiges dull white to pale yellowish-white; tail quite long, dusky olive, conspicuously whitish to pale ochraceous on outer edges and tips; face and chin whitish, throat and underparts yellow, distinctly tinged buffy to ochraceous on throat and breast; iris whitish to yellowish-white; bill long and thin, black; legs grey. Sexes alike, female slightly smaller than male. Juvenile has brown eyes. Race *intermedia* has paler throat, less ochraceous on breast, slightly smaller bill.
Voice. Very vocal; main song a short series of notes, the first two louder and higher than others, "cheep chee deleet-eet", sometimes preceded by several brief "kip" notes, also given repeatedly at 1-second intervals as dawn song; also a long descending series of evenly spaced whistled notes, "chee, cheep cheep, cheep, chew chew chew", by both sexes in syncopated duet; and abrupt "pit", sometimes in short series.
Habitat. Deciduous and semi-deciduous woodland, gallery forest, seasonally flooded forest, shrubby second growth, and mangroves; sea-level to 400 m.
Food and Feeding. Ants (Hymenoptera) and spiders (Araneae) recorded as eaten. Usually alone or in pairs; occasionally joins mixed-species flocks. Forages actively at all levels in dense foliage, often cocks tail slightly; perch-gleans and hover-gleans in foliage and twigs, behaviour like that of a vireo (Vireonidae).
Breeding. Jan-Jul in Venezuela and Surinam. Nest a simple, thin open cup, placed at 2-5 m or higher on fork of tree branch. No information on clutch size and incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Common to fairly common. Especially common on Venezuelan *llanos*.
Bibliography. Anon. (2001g), Chapman (1917c), Cory & Hellmayr (1927), Fitzpatrick (1980c, 1985b), Green (2001a), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Lanyon (1988b), Ridgely & Tudor (1994), Ridgway (1907), Snyder (1966), Strewe & Navarro (2003), Tostain *et al.* (1992), Wetmore (1939), Zimmer & Whittaker (2000).

PLATE 24 ➤

PLATE 24

inches 2
cm 5



Genus *MYIOTRICCUS* Ridgway, 1905

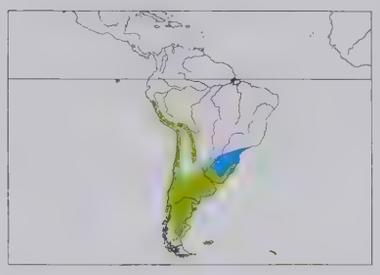
132. **Ornate Flycatcher**

Myiotriccus ornatus

French: Tyranneau orné **German**: Schmucktyrann **Spanish**: Mosquerito Adornado

Taxonomy. *Tyrannula ornata* Lafresnaye, 1853, Bogotá, Colombia.
Distinctive monotypic genus of uncertain affinities, hypothesized as closest to *Myiophobus* on basis of cranial characters, bright crown patch and cup-shaped nest. Four subspecies recognized.
Subspecies and Distribution.
M. o. ornatus (Lafresnaye, 1853) - C Andes and W slope at N end of E range, in Colombia.
M. o. stellatus (Cabanis, 1873) - W Colombia and W Ecuador.
M. o. phoenicurus (P. L. Sclater, 1855) - E Andes of SE Colombia, E Ecuador and Peru (N of R Marañón).
M. o. aureiventris (P. L. Sclater, 1874) - C & SE Peru (Huánuco S to Puno).

Descriptive notes. 11·4 cm; 11-14 g. Strikingly patterned flycatcher. Nominate race has black on face and crown, conspicuous white crescent-shaped preocular patch, semi-concealed bright yellow coronal patch; rest of head, and throat, grey, upperparts deep olive, rump bright golden-yellow; wings dusky black; tail bright rufous at base, dusky black on distal half; breast rich olive, belly bright golden-yellow; iris dark brown; bill black; legs black. Sexes alike, female slightly smaller than male. Juvenile undescribed. Races vary mainly in colour of tail: *stellatus* has tail yellowish at base, is also much smaller than nominate, loral crescent more restricted, often interrupted in middle; *phoenicurus* has tail entirely rufous; *aureiventris* has back slightly paler green, lighter grey throat with grey extending farther down, breast paler green. Voice. Very loud, ringing, single "peek" or "wheep", repeated frequently while actively foraging or perched, occasionally in rapid series.
Habitat. Humid montane forest and older second growth, often in old treefall gaps and dark, mossy ravines and stream edges; mainly 600-2300 m, locally down to 300 m near foothills.
Food and Feeding. Stomach contents in SE Peru contained 193 prey items, of which beetles (Coleoptera) 47%, Hymenoptera 34% (ants 26%, bees and wasps 8%), bugs (Hemiptera) 10%, homopterans (planthoppers) 6%, other 3%. Forages singly or, more often, in pairs; joins mixed-species flocks only when they move through its small territory. Perches upright at low to middle levels on open, exposed perches, almost always in deep shade; pauses for long periods, actively moving head about in search of aerial prey. Sallies mainly into air, frequently returns to same or nearby perch. Highly sedentary, found in same foraging zone day after day.
Breeding. Nest in Mar and birds in breeding condition in May in Colombia; in breeding condition in Sept-Dec in SE Peru. Single nest found, cup-shaped, made of rootlets, placed 1·3 m up on steep earth bank and well concealed; contained one nestling. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common. Occurs in Tambito Nature Reserve, in Colombia; in Ecuador, found in Río Palenque Science Centre and several other protected areas, and common in Cordillera de Mache at Bilsa (Esmeraldas).
Bibliography. Begazo (1995), Birdsley (2002), Butler (1979), Chapman (1917c), Clements & Shany (2001), Cory & Hellmayr (1927), Fitzpatrick (1985b), Hilty (1997), Hilty & Brown (1986), Lanyon (1986a, 1988b), Meyer de Schauensee (1982), Miller (1963), Restrepo & Gómez (1998), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Stotz *et al.* (1996), Strewe (2000b), Traylor (1958, 1977), Williams & Tobias (1994), Zimmer (1939b).



Genus *TACHURIS* Lafresnaye, 1836

133. **Many-coloured Rush-tyrant**

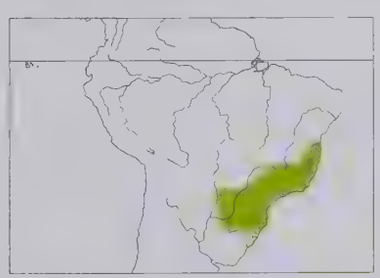
Tachuris rubrigastra

French: Tyranneau omnicolore **German**: Vielfarben-Tachurityrann **Spanish**: Sietecolores
Other common names: Many-coloured Tyrant

Taxonomy. *Sylvia rubrigastra* Vieillot, 1817, Paraguay.
Distinctive monotypic genus hypothesized by some as being closest to *Pseudocolopteryx*. Four subspecies recognized.
Subspecies and Distribution.
T. r. libertatis Hellmayr, 1920 - W Peru (La Libertad S to Lima and N Ica).
T. r. alticola (Berlepsch & Stolzmann, 1896) - C & SE Peru (Junín S to Puno), W Bolivia (La Paz, Oruro) and NW Argentina (Jujuy, Tucumán).
T. r. loaensis R. A. Philippi [Bañados] & Johnson, 1946 - N Chile (Antofagasta at confluence of R Loa and R San Salvador).
T. r. rubrigastra (Vieillot, 1817) - Paraguay, SE Brazil (S São Paulo, Rio Grande do Sul), C & W Chile (Atacama S to Chiloé and Aisén), Argentina (Misiones, and from Santa Fe to Buenos Aires and S to Santa Cruz) and Uruguay.
Descriptive notes. 11-11·5 cm; 6·5-8 g. Vibrantly coloured, the most colourful of all tyrannids. Male nominate race has crown black, prominent golden supercilium, semi-concealed red coronal

patch and slight crest; lores and auriculars glossy blue to black, giving masked appearance; nape ochraceous, edging into bright moss-green back; wings black, prominent white bar formed by white edging of wing-coverts and tertials; tail black, outer rectrices white; upper throat white; breast and belly bright yellow, black bars near bend of wing (nearly meeting at centre), crissum bright red to orange-red, sometimes a faded rose-pink; iris pale, bluish; bill black; tarsi notably long, black. Female has same general pattern as male, slightly duller colours, coronal patch smaller. Immature lacks blue on facial mask, green upperparts may be scaled yellow, breast and belly paler yellow, breastbars absent. Race *libertatis* has whiter throat and belly and greener, less prominent supercilium than nominate; *alticola* has darker, more blackish-green back, paler yellow supercilium, is slightly larger; *loaensis* is smaller, has more extensive white on throat, stronger yellowish-ochre on neck and breast, pale greyish-white belly, supercilium tinged green, tail edged brighter white. Voice. Bizarre, rapid series of insect-like "tic" notes, and musical "piwup bzzzzt" or "piwup piwuprrrrp" with gurgled quality and buzzing element.
Habitat. Extensive reedbeds, marshes, and grassy lake edges, very rarely leaving patches of reeds for adjacent growth; sea-level to 4200 m.
Food and Feeding. Insects. Forages alone or in family groups in dense rushes, usually well concealed. Mainly perch-gleans items from reed edges or floating vegetation, often clinging or hanging upside-down from reed stems, sometimes sallying out for aerial prey or flight-gleaning insects from water surface; sometimes runs or hops on ground, mud or floating vegetation in search of prey.
Breeding. Eggs in Oct, nestlings in Sept and fledglings in Feb in Peru; in breeding condition in Sept and Oct and fledgling in Feb in SE Brazil. Very distinctive, deep, tight, cone-shaped cup-nest attached by its side to single reed, usually over water; uses wet pieces of reed leaf which, after drying, achieve consistency of cardboard. Clutch 3 eggs, rarely 4; no information on incubation and fledging periods.
Movements. Migratory patterns poorly understood; populations in S parts of range move N during austral winter; one individual recorded 170 km offshore from Rio Grande do Sul, in Brazil, in Mar 1960.
Status and Conservation. Not globally threatened. Locally common; often found in scattered, loose colonies, with intervening suitable habitat apparently unoccupied. In NW of range, abundant at L Junín (Peru), and common at L Titicaca and L Poopó (Bolivia). Occurs in many protected areas, e.g. Costanera Sur Ecological Reserve, in Argentina.
Bibliography. Babarskas *et al.* (2003), Belton (1985), Canevari *et al.* (1991), Chebez (1994), Clements & Shany (2001), Cory & Hellmayr (1927), Couve & Vidal-Ojeda (2003), Darrieu (1987), Fitzpatrick (1985b), Fjeldså (1983), Fjeldså & Krabbe (1990), Flores & Capriles (1998), Harris (1998), Hayes (1995), Jaramillo (2003), Johnson (1967), Klimaitis & Moschione (1987), Lanyon (1988b), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Nores *et al.* (1983), de la Peña (1987, 1988), Ridgely & Tudor (1994), do Rosário (1996), Schönwetter & Meise (1968), Sick (1993, 1997), Smith (1971), Stotz *et al.* (1996), Traylor (1977), Traylor & Fitzpatrick (1982), Wetmore (1926), Zimmer (1940b).

Tribe PLATYRINCHINI



Genus *MYIORNIS* W. Bertoni, 1901

134. **Eared Pygmy-tyrant**

Myiornis auricularis

French: Microtyran oreillard **German**: Ohrfleck-Zwergtyrann **Spanish**: Mosqueta Enana

Taxonomy. *Platyrhynchos auricularis* Vieillot, 1818, Rio de Janeiro, Brazil.
Forms a superspecies with *M. albiventris*, and sometimes considered conspecific. Two subspecies recognized.
Subspecies and Distribution.
M. a. cinereicollis (Wied, 1831) - E Brazil (SE Bahia, Minas Gerais, Espírito Santo).
M. a. auricularis (Vieillot, 1818) - SE Paraguay, NE Argentina (Misiones) and SE Brazil (Rio de Janeiro S to Rio Grande do Sul).

Descriptive notes. 7 cm; 5 g. Very small, round-bodied, large-headed tyrannid. Has buffish-cinnamon area around eye, whitish auriculars, black patch below eye, black crescent-shaped patch at rear edge of auriculars ("eared" appearance); bright olive above, crown tinged brown, nape and neck grey; wings dusky, bright olive-yellow edgings and two indistinct wingbars; tail dusky; throat and upper breast white, finely streaked black, rest of underparts bright yellow, streaked olive; iris orange; bill blackish; feet flesh-coloured. Sexes alike. Juvenile undescribed. Race *cinereicollis* is highly variable, has auriculars usually paler than nominate, buffy whitish. Voice. Series of "pic" notes followed by musical trill, "pic-pic-pic-pree-ee-ee-ee-ee"; wings produce whirring or buzzing sound in flight.

On following pages: 135. White-bellied Pygmy-tyrant (*Myiornis albiventris*); 136. Black-capped Pygmy-tyrant (*Myiornis atricapillus*); 137. Short-tailed Pygmy-tyrant (*Myiornis ecaudatus*); 138. Northern Bentbill (*Oncostoma cinereigulare*); 139. Southern Bentbill (*Oncostoma olivaceum*); 140. Scale-crested Pygmy-tyrant (*Lophotriccus pileatus*); 141. Long-crested Pygmy-tyrant (*Lophotriccus eulophotes*); 142. Double-banded Pygmy-tyrant (*Lophotriccus vitiosus*); 143. Helmeted Pygmy-tyrant (*Lophotriccus galeatus*); 144. Pale-eyed Pygmy-tyrant (*Atalotriccus pilaris*).

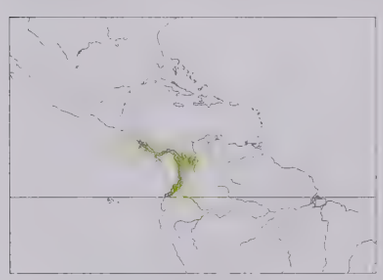
Habitat. Humid forest and forest edge, usually in dense, shrubby growth along edges, less frequent within forest itself; sometimes moves beyond forest edge to low satellite trees in meadows. To 1250 m.
Food and Feeding. Insects. Forages mostly in lower and middle growth usually at 2-3 m; perches in the open, moving rapidly and changing perches frequently. Makes buzzing flights to strike leaves for prey.
Breeding. Nests found in Dec. Nest purse-shaped, with side entrance, made of twigs, stems and dry leaves, sometimes with hanging "tail", suspended from horizontal branch c. 1-3 m up in bush. Clutch 2 or 3 eggs. Nest (amazingly) parasitized by Pavonine Cuckoo (*Dromococcyx pavoninus*). No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common. Although much suitable habitat for this species has been destroyed or heavily degraded, it still occurs in many national parks and other protected areas throughout its range.
Bibliography. Brooks *et al.* (1993), Canevari *et al.* (1991), Cory & Hellmayr (1927), Cracraft (1985), Darrieu (1987), Hayes (1995), Lowen *et al.* (1996), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Navas & Bó (1993a), de la Peña (1988), Ridgely & Tudor (1994), do Rosário (1996), Saibene *et al.* (1996), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977).

135. **White-bellied Pygmy-tyrant**

Myiornis albiventris

French: Microtyran à ventre blanc **Spanish**: Mosqueta Ventriblanca
German: Weißbauch-Zwergtyrann
Other common names: White-breasted Pygmy-tyrant

Taxonomy. *Orchilus albiventris* Berlepsch and Stolzmann, 1894, La Merced, 2600 feet [c. 790 m], Junín, central Peru.
Forms a superspecies with *M. auricularis*, and sometimes considered conspecific. Monotypic.
Distribution. Locally at base of E slope of Andes in C & E Peru (Junín, Huánuco, Pasco, Ayacucho, E Puno) and N Bolivia (La Paz, Cochabamba, W Santa Cruz).



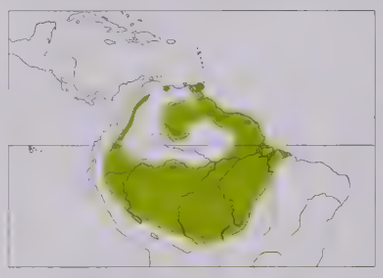
Descriptive notes. 7 cm; 5-6 g. Very small, round-bodied tyrannid with large-headed appearance. Has buff-whitish area around eye, greyish crescent-shaped auricular patch; bright olive above, crown tinged brown; wings dusky, bright olive-yellow edgings and two indistinct wingbars; tail dusky; throat and upper breast whitish, faintly flammulated with grey, rest of underparts white, tinge of yellowish-olive on side and crissum; iris reddish; bill blackish; legs flesh-coloured. Differs from *M. auricularis* in e.g. less conspicuous auricular crescent, paler underparts, slightly shorter tail. Sexes alike. Juvenile undescribed. Voice. Flat, fast sequence of notes, "dr-rr-rr-rr-rr-t", delivered several times in series.
Habitat. Humid lower montane and foothill forest and edges, at 400-1200 m.
Food and Feeding. Insects. Forages in lower and middle storeys, favouring openings; often perches in the open a few centimetres from leaves, making fast, buzzy sallies to strike at prey.
Breeding. Not documented.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon. Poorly known species. In Bolivia, occurs in Pilón Lajas Biosphere Reserve and Madidi National Park; frequent along lower part of the Villa Tunari road, in Cochabamba.
Bibliography. Clements & Shany (2001), Collar *et al.* (1994), Cory & Hellmayr (1927), Hennessey, Herzog, Kessler & Robinson (2003), Hennessey, Herzog & Sagot (2003), Perry *et al.* (1997), Remsen & Traylor (1989), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Stotz *et al.* (1996), Traylor (1977), Zimmer (1940a).

136. **Black-capped Pygmy-tyrant**

Myiornis atricapillus

French: Microtyran à calotte noire **Spanish**: Mosqueta Capirotada
German: Schwarzkappen-Zwergtyrann

Taxonomy. *Orchilus atricapillus* Lawrence, 1875, Talamanca, Costa Rica.
Formerly placed in a separate genus, *Perissotriccus*, along with *M. ecaudatus*. The two form a superspecies and were previously treated by many authors as conspecific. Monotypic.
Distribution. Costa Rica S to W Colombia and NW Ecuador.



Descriptive notes. 6·5 cm; 5 g. Tiny, one of the smallest passerines, with almost tail-less appearance. Male has black crown, prominent white supraloral spot and white "spectacles", slate-grey nape and side of face; upperparts bright olive; wings dusky with olive-green edgings, brighter yellow on secondaries; tail extremely short, mostly black; throat and upper breast white, side of neck and breast pale grey, underparts washed pale yellow; iris dark reddish-brown; bill black; legs pink to orangish. Female has only forehead black, rest of cap more sooty. Juvenile has cap dark sooty brown, upperparts brownish, edgings of wing-coverts and underparts tinged buff. Voice. High-pitched and ventriloquial, insect-like or frog-like; typically, a soft trilled, purr-like call, also given in series, becoming long series of rapid "tseeyp" or "creek" notes.
Habitat. Lower and middle growth of humid forest, forest gaps and edges, shrubby growth in clearings, also adjacent second growth and plantations; to 900 m.
Food and Feeding. Stomach contents in Costa Rica included 205 items, of which homopteran bugs 26%, beetles (Coleoptera) 25%, arachnids 15%, hymenopterans 13%, lepidopteran larvae 10%, orthopterans 6%, other 5%. Forages usually singly or in pairs, not following mixed-species flocks, mostly high in canopy, venturing lower in areas near gaps and edges. Makes quick, buzzy flights, gleaning prey from undersides of leaves, occasionally hovering. Inconspicuous owing to infrequent movements.
Breeding. Eggs in late Mar in Panama and mid-Apr in Costa Rica. Bag-like domed nest c. 15 cm long, 9 cm in diameter, with side entrance in middle and dangling streamer, constructed from green moss, egg-chamber lined with fine yellow fibres and plant down, suspended from slender twig of fallen branch or from thorny tree c. 1-4 m above ground. Clutch 2 eggs; nest apparently tended only by female; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common, but often overlooked. Occurs in Tinigua National Park, in Colombia, and Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru. Common along lower Buenaventura road in Valle (Colombia).
Bibliography. Anon. (1998a), Chapman (1917c), Cory & Hellmayr (1927), Eisenmann (1955), Haffer (1974, 1975), Hilty & Brown (1986), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Salaman (1994), Sherry (1984), Slud (1960, 1964), Stiles (1985), Stiles & Skutch (1989), Stiles *et al.* (1999), Stotz *et al.* (1996), Strewe (2000b), Traylor (1977), Wetmore (1972), Willis (1980), Willis & Eisenmann (1979).

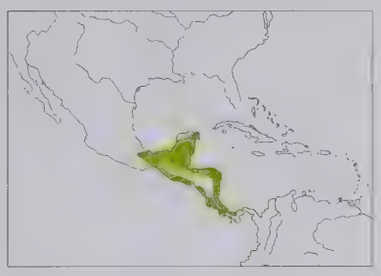
137. **Short-tailed Pygmy-tyrant**

Myiornis ecaudatus

French: Microtyran à queue courte **Spanish**: Mosqueta Colicorta
German: Stummelschwanz-Zwergtyrann

Taxonomy. *T[odirostrum] ecaudatum* d'Orbigny and Lafresnaye, 1837, Yuracarés, Bolivia.
Formerly placed in a separate genus, *Perissotriccus*, along with *M. atricapillus*. The two form a superspecies and were previously treated by many authors as conspecific. Two subspecies recognized.
Subspecies and Distribution.
M. e. miserabilis (Chubb, 1919) - Venezuela (Carabobo, Mérida, Táchira, Barinas, N Amazonas, Bolívar), Trinidad, the Guianas, E Colombia (Meta) and N Brazil (Amapá).
M. e. ecaudatus (d'Orbigny & Lafresnaye, 1837) - Amazon Basin of E Ecuador, E Peru, Brazil (from Amazonas E to Pará) and N Bolivia (S to Cochabamba and Santa Cruz).

Descriptive notes. 6·5 cm; 4·2 g. Tiny, the smallest passerine, looking nearly tail-less. Nominate race has dark grey head with very prominent white supraloral spot, white eyering and blackish lores, giving "spectacled" appearance; upperparts bright olive-green; wings dusky with bright yellow edgings and indistinct wingbars; tail extremely short, mostly black; throat and underparts white, crissum tinged pale yellow; iris dark; bill long for bird of this size, black; legs flesh-coloured. Sexes alike. Juvenile is similar to adult. Race *miserabilis* has darker, duller green back, darker grey on top of head and hindneck, greyer side of chest, darker legs. Voice. High-pitched and faint, very insect-like or frog-like, easily mistaken as a non-bird sound; most often a soft trilled, purr-like call, sometimes leading into long series of short, squeaky "creek" notes beginning slowly and accelerating, "cre'e'e'e'e', k'e'e'e'e"; buzzing sound produced by wings in flight.
Habitat. Humid forest, forest gaps and edges, also adjacent clearings and second growth; lowlands and foothills to 950 m.
Food and Feeding. Insects. Usually found singly or in pairs, rarely following mixed-species flocks. Forages mostly high in canopy, venturing lower in areas near forest gaps and edges; often associated with older treefall gaps with high vine thickets. Makes quick, buzzy flights to strike tops or undersides of leaves for insects; occasionally hovers. Inconspicuous owing to infrequent movements.
Breeding. Eggs from mid-Jun to mid-Sept in Amazonian Brazil; nest with nearly fledged young in late Aug and single breeding record in Jan in Venezuela; one Jan breeding record in Surinam; birds in breeding condition in Feb-May (and fledgling seen in Mar) in Colombia, and Aug-Oct in SE Peru. Bag-like domed nest with side entrance, small awning projecting above entrance hole, and dangling loose streamer, measurements of one 25 cm long (including tail 11 cm), 9-11 cm in diameter, entrance 2·5 × 4 cm; constructed from green moss, fine grass blades, macerated dry leaves, fragments of disintegrating weeds, and rootlets, sometimes mixed with varying amount of hair, brood-chamber profusely lined with hair, or only floor lined with fine plant fibres, bits of grass and buff and white pappi or seed plumes (of unidentified composite); suspended from branch 1-6 m above ground. Clutch 2 eggs; incubation probably by female alone (on basis of presence of incubation patch); both parents feed nestlings and remove faecal sacs; no information on duration of incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common; frequently overlooked. Occurs in many national parks and other protected areas throughout its range.
Bibliography. Bates & Parker (1998), Blake (1962), Chapman (1921), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), ffrench (1991), Fitzpatrick (1980c), Friedmann (1948), Haffer (1974), Haverschmidt (1968), Haverschmidt & Mees (1994), Hennessey, Herzog, Kessler & Robinson (2003), Hilty (2003), Hilty & Brown (1986), Ihering (1901), McNeil & Martínez (1968), Meyer de Schauensee (1982), Novaes (1978a), Oren & Parker (1997), Perry *et al.* (1997), Pinto (1953), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schönwetter & Meise (1968), Schubart *et al.* (1965), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Temple (2002), Tostain *et al.* (1992), Traylor (1977), Wetmore (1972), Willard *et al.* (1991), Zimmer (1940a).



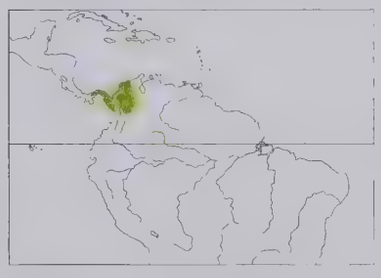
Genus *ONCOSTOMA* P. L. Sclater, 1862

138. **Northern Bentbill**

Oncostoma cinereigulare

French: Bec-en-arc cendré **Spanish**: Mosquerito Piquicurvo Norteño
German: Graukehl-Krummschnabeltyrann
Other common names: Bent-billed Flycatcher, Grey-throated Bentbill

Taxonomy. *Todirostrum cinereigulare* P. L. Sclater, 1857, Córdoba, Veracruz, Mexico.
Has been suggested by some authors that genus be joined with closely affiliated *Hemitriccus* or *Lophotriccus*; bill morphology and peculiar voice, however, viewed by others as sufficiently distinct to support retention of separate genus. Forms a superspecies with *O. olivaceum*, and sometimes considered conspecific. Distribution somewhat uncertain; one specimen from NW Antioquia, in Colombia, identified as belonging to present species on basis of yellow underparts, possibly representing disjunct population separated from nearest one (W Panama) by 400-600 km; slight variation in belly colour of present species, however, leads to questions about true identity of this specimen. Monotypic.
Distribution. S Mexico S to W Panama (possibly in Bocas del Toro and N Veraguas).



Descriptive notes. 9·5-10·5 cm; 4·5-7 g. Distinctive bill with significant downward curve. Has grey crown contrasting strongly with olive upperparts; wings dusky with lemon-yellow edgings; face, throat and breast pale grey, streaked olive, lower underparts and crissum washed pale lemon-yellow, flanks tinged olive; iris pale yellow; bill grey, flesh-coloured base; legs flesh-coloured. Differs from *O. olivaceum* most clearly in having ground colour of throat and breast greyish-white, as opposed to yellowish-white. Sexes alike. Juvenile has olive crown, narrow buffy wingbars and buffy edges of remiges, dusky bill. Voice. Guttural insect-like or toad-like trill, "grrrr" or "chiurrrrrrrr", sometimes with introductory note, "t-trrrrrr"; also a descending, melodious trill.
Habitat. Thickets and dense undergrowth of humid lowland forest, forest edge, tropical deciduous forest, and secondary woodland and scrubby semi-open areas; sea-level to 1200 m, locally to 1450 m.
Food and Feeding. Arthropods; occasionally eats small berries. Stomach contents in Costa Rica included 98 items, of which beetles (Coleoptera) 33%, arachnids 22%, homopteran bugs 15%, orthopterans 12%, lepidopterans 8%, flies (Diptera) 4%, other 6%. Forages usually alone or in pairs, near ground in dense vegetation; easily overlooked. Sallies upwards to strike undersides of leaves, moves quickly to new perch.
Breeding. Birds in breeding condition in early Apr in El Salvador. Nest, built by female, roundish, vertically elongated, domed, with side entrance, constructed from pale-coloured plant fibres, suspended from leaf or twig from a few centimetres to 4 m above ground. Clutch 2 eggs; incubation and brood-tending undertaken by female alone; no information on duration of incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to common. Occurs in several national parks and other protected areas throughout its reasonably large range. Fairly adaptable; tolerates somewhat disturbed habitat.
Bibliography. Anon. (1998a), Binford (1989), Brodkorb (1943), Cory & Hellmayr (1927), Dearborn (1907), Fitzpatrick (1976, 1985b), Harrowes (1936), Howell & Webb (1995a), Kricher & Davis (1992), Land (1970), Lee Jones (2004), Monroe (1968), Payne (1984), Paynter (1955, 1957), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Romero-Zambrano & Rodríguez (1980), Schönwetter & Meise (1968), Sherry (1984), Skutch (1960), Slud (1960, 1964, 1980), Smithe (1966), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Thurber *et al.* (1987), Traylor (1977), Traylor & Fitzpatrick (1982), Wetmore (1941, 1943, 1944, 1972).

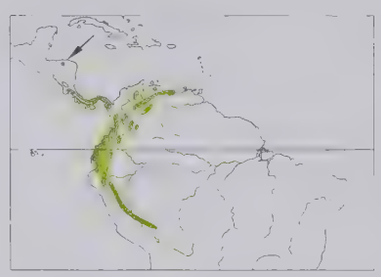
139. **Southern Bentbill**

Oncostoma olivaceum

French: Bec-en-arc de Lawrence **Spanish**: Mosquerito Piquicurvo Sureño
German: Gelbkehl-Krummschnabeltyrann
Other common names: Lawrence's Bent-billed Tyrant

Taxonomy. *Todirostrum olivaceum* Lawrence, 1862, Lion Hill, Canal Zone, Panama.
Has been suggested by some authors that genus be joined with closely affiliated *Hemitriccus* or *Lophotriccus*; bill morphology and peculiar voice, however, viewed by others as sufficiently distinct to support retention of separate genus. Forms a superspecies with *O. cinereigulare*, and sometimes considered conspecific. Monotypic.
Distribution. C & E Panama and NW Colombia.

Descriptive notes. 9 cm; 6-7 g. Distinctive bill with downward-arching culmen. Plumage is entirely olive above, whitish supraloral area; wings dusky, two indistinct greenish-yellow wingbars and lemon-yellow edgings, tail dusky olive; throat and breast yellowish-white, streaked olive, rest of underparts olive-yellow with some olive streaking, belly yellow; iris pale yellow to dusky; bill grey; legs flesh-coloured. Differs from *O. cinereigulare* most clearly in having ground colour of throat and breast yellowish-white, as opposed to greyish-white. Sexes alike. Juvenile undescribed. Voice. Guttural insect-like or toad-like trill, "grrrrrrrr", sometimes with introductory note, "pt-trrrrrrrr".
Habitat. Humid tropical forest and forest edge, dense secondary-forest borders, sometimes lighter woodland, thickets and shrubby clearings; sea-level to 1000 m.
Food and Feeding. Arthropods; occasionally eats small berries. Forages usually alone or in pairs, near ground in dense vegetation; often overlooked. Sallies upwards to strike undersides of leaves, moves quickly to new perch.
Breeding. Single nests in late Apr and early Aug in Panama; birds in breeding condition in Feb-Jun in Colombia. Small, roundish, domed nest with side entrance near top, small awning projecting above entrance, suspended from slender tree branch 1-4 m above ground. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common; often overlooked. Numerous in Tayrona National Park, in Colombia.
Bibliography. Anon. (1998a), Cory & Hellmayr (1927), Delgado (1985), Eisenmann (1955), Harrowes (1936), Hilty & Brown (1986), Meyer de Schauensee (1982), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Schönwetter & Meise (1968), Skutch (1960), Stotz *et al.* (1996), Strewe & Navarro (2003), Traylor & Fitzpatrick (1982), Wetmore (1972), Willis (1972, 1980), Willis & Eisenmann (1979).



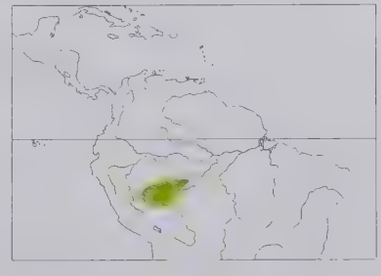
Genus *LOPHOTRICCUS* Berlepsch, 1884

140. **Scale-crested Pygmy-tyrant**

Lophotriccus pileatus

French: Microtyran chevelu **German**: Rot-Schuppenkopftyrann **Spanish**: Cimerillo Andino

Taxonomy. *E[uscarthmus] pileatus* Tschudi, 1844, Valley of Vitoc, Junín, Peru.
Five subspecies recognized.
Subspecies and Distribution.
L. p. luteiventris Taczanowski, 1884 - E Honduras (foothills of the Olancho), Costa Rica and Panama (E to E Darién).
L. p. sanctaeluciae Todd, 1952 - NW Venezuela (from W Zulia E to Miranda and Táchira) and adjoining Colombia.
L. p. squamaecrista (Lafresnaye, 1846) - Andes of Colombia and W Ecuador.
L. p. pileatus (Tschudi, 1844) - Andes of E Ecuador and E Peru (S to Cuzco).
L. p. hypochlorus Berlepsch & Stolzmann, 1906 - SE Peru from Cuzco (Urubamba Valley) S to Puno (R Madre de Dios).



Descriptive notes. 9·7 cm; 7-8 g. Distinctive, crested tyrannid. Nominate race has long crown feathers black with rufous edging, forming distinctive crest (sometimes erected and fanned, extends beyond rear crown when flat), whitish lores; upperparts olive; wings dusky, two buffy wingbars and yellow edgings, tail dusky; throat and upper breast white, streaked olive, flanks and underparts washed light yellow; iris yellow; bill grey; legs flesh-coloured. Sexes similar, female with crest less developed than male's. Juvenile undescribed. Race *luteiventris* has crown brown, lesser wing-coverts edged olive-green, median and greater coverts tipped greyish-white to yellowish olive-green, primaries edged olive-green, secondaries broadly edged yellowish-white, iris colour variable, orange-yellow to yellow; *sanctaeluciae* has throat and breast pale yellow, indistinct yellowish wingbars, flight-feathers edged olive; *squamaecrista* has wing-coverts less conspicuous with greenish edges, throat and chest with broader and darker streaks, flanks paler yellowish; *hypochlorus* is much yellower below, lateral edges of throat feathers olive-yellow instead of white, chest tinged greenish, abdomen bright yellow, flanks more greenish. Voice. Extremely loud trill sounding like a police whistle, as if from a much larger bird, often given persistently throughout day; also a series of sharp "preek" notes, sometimes widely spaced.
Habitat. Humid forest, older second growth, also in gaps and edges; foothills and lower slopes at 700-2100 m, locally 300-2300 m, occasionally down to 100 m. Favours stands of bamboo, especially on E slope of Andes.
Food and Feeding. Stomach contents in SE Peru included 30 prey items, of which beetles (Coleoptera) 62%, hymenopterans 16% (wasps 6%, ants 10%), hemipteran bugs 13%, homopterans 3%, arachnids 3%, other 3%. Perches inconspicuously in middle storey or lower canopy of dense forest; makes quick sallies out and upwards from hidden perch to strike at insects from undersides of leaves.
Breeding. Birds in breeding condition in Mar-Jun in Colombia. Bag-like domed nest with lateral side entrance, small awning projecting above entrance, and long, thin dangling streamer, constructed from fine, pale-coloured fibres, suspended from twig c. 3·5 m above ground. Clutch 2 eggs; apparently only female attends nest; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common. Numerous both on Cerro Campana and in Cerro Azul-Jefe area, in Panama. Occurs in many national parks and other protected areas throughout its range. Given its tolerance of degraded and isolated habitats and its relatively large range, it is thought not likely to become threatened.
Bibliography. Anon. (1998a), Begazo (1995), Chapman (1921), Clements & Shany (2001), Cory & Hellmayr (1927), Hilty (1997, 2003), Hilty & Brown (1986), Howell & Webb (1995a), Meyer de Schauensee (1982), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Salaman (1994), Schönwetter & Meise (1968), Skutch (1967), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Traylor (1977), Wetmore (1944, 1972), Williams & Tobias (1994), Zimmer (1930, 1940a).

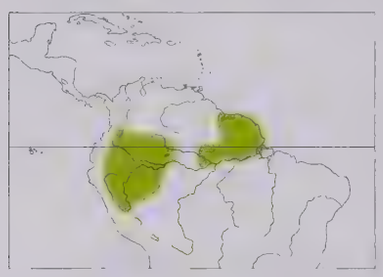
141. **Long-crested Pygmy-tyrant**

Lophotriccus eulophotes

French: Microtyran eulophe **Spanish**: Cimerillo Crestilargo
German: Weißbauch-Schuppenkopftyrann

Taxonomy. *Lophotriccus eulophotes* Todd, 1925, River Purús, Amazonas, Brazil.
Probably forms a superspecies with *L. vitiosus*, and sometimes treated as conspecific. Monotypic.
Distribution. SW Amazonian Brazil (drainage of R Purus), SE Peru and NW Bolivia (Pando).

Descriptive notes. 10 cm; 6·5-8 g. Has long black crown feathers with grey edging, forming crest (sometimes erected and fanned, extends beyond rear crown when flat), whitish lores; upperparts olive, with wings and tail dusky; throat and underparts whitish, streaked grey; iris whitish-yellow; bill grey; legs flesh-coloured. Sexes alike. Juvenile undescribed. Voice. Typically, a series of 5-8 "tic" notes; also, occasionally utters a slightly descending trill.
Habitat. Riverine forest, swamp-forest, tall road-edge second growth, large stands of *Guadua* bamboo, also bamboo-dominated undergrowth, forest edges, and large treefall gaps. Occurs up to 400 m.



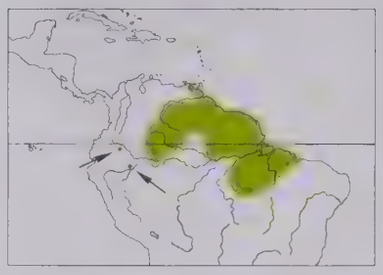
Food and Feeding. Insects. Forages mainly at 4-10 m, making short (1 m) upward strike-sallies to glean items from leaves and stems; sometimes follows mixed-species flocks in bamboo.
Breeding. Not documented.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Southeast Peruvian Lowlands EBA. Uncommon to fairly common, but local. Occurs in Manu National Park and Biosphere Reserve, in Peru. SE Peruvian lowland forests remain relatively intact, but mining, oil extraction and other development schemes, coupled with associated road-building and human intrusion, pose serious future threats; even the integrity of large protected areas such as Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone is not assured.
Bibliography. Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Forrester (1993), Gyldenstolpe (1950), Hennessey, Herzog & Sagot (2003), Meyer de Schauensee (1982), Parker & Remsen (1987), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Whittaker & Oren (1999).

142. **Double-banded Pygmy-tyrant**

Lophotriccus vitiosus

French: Microtyran bifascié **German**: Grau-Schuppenkopftyrann **Spanish**: Cimerillo Bilistado
Other common names: Golden-scaled Pygmy-tyrant (*congener*)

Taxonomy. *Cometornis vitiosus* Bangs and T. E. Penard, 1921, Sarayacu, River Ucayali, Peru.
Probably forms a superspecies with *L. eulophotes*, and sometimes treated as conspecific. Race *congener* thought by some to be possibly a separate species. Four subspecies recognized.
Subspecies and Distribution.
L. v. guianensis J. T. Zimmer, 1940 - the Guianas and NE Brazil (N of Amazon in N Pará and Amapá).
L. v. affinis J. T. Zimmer, 1940 - SE Colombia (from Meta S to Putumayo, Vaupés and Amazonas), NW Brazil (upper R Negro), E Ecuador and NE Peru (N of Amazon).
L. v. vitiosus (Bangs & T. E. Penard, 1921) - E Peru from E San Martín and S Loreto S to Huánuco.
L. v. congener Todd, 1925 - W Brazil (SW Amazonas) and E Peru (E of R Ucayali).



Descriptive notes. 10 cm; 6-8·5 g. Nominate race has long black crown feathers with grey edging, forming crest (erected and fanned less often than that of *L. pileatus*, extends beyond rear crown when flat), whitish lores; upperparts olive; wings dusky, two fairly distinct greenish-yellow wingbars and edgings, bend of wing yellow (usually concealed); tail dusky; throat and upper breast white, streaked dusky olive, flanks and crissum washed light yellow; iris straw-yellow; bill grey; legs flesh-coloured. Sexes similar, female crest less developed than male's. Juvenile undescribed. Race *guianensis* has stronger yellow underparts than nominate, crown feathers edged darker grey; *affinis* has breast and sides tinged olive, distinctly yellower belly; *congener* has whiter underparts, black crown feathers edged with buff-yellow. Voice. Harsh, buzzy trill, "turrrrrrr", often delivered in series; not so distinctly loud as that of *L. pileatus*.
Habitat. Humid tropical *terra firme* and *várzea* forest, forest borders, and second-growth forest, to 800 m.
Food and Feeding. Probably feeds mainly on insects. Perches inconspicuously in middle storey and canopy, and makes quick upward sallies to strike at undersides of leaves; rarely joins mixed-species flocks.
Breeding. Nests during dry season in Guianan region; nest-building in late Aug in NW Brazil and nearly finished nest observed in mid-Sept in Surinam; nest with 2 eggs in late Aug, Ecuador. Bag-like domed nest with downward-facing lateral entrance near bottom, small awning projecting above entrance hole, and short dangling tail, one 60 cm long (including tail), another 12 cm long and 7 cm in diameter, constructed from green moss and dry grass; suspended from tree branch c. 4 m above ground, sometimes over stream. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Rather poorly known species.
Bibliography. Blake (1962), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Friedmann (1948), Greeney *et al.* (2004), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty & Brown (1986), Meyer de Schauensee (1982), Novaes (1978a), Penard & Penard (1910), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977), Zimmer (1930, 1940a).

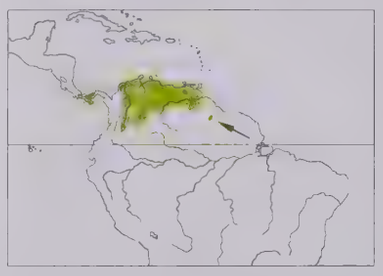
143. **Helmeted Pygmy-tyrant**

Lophotriccus galeatus

French: Microtyran casqué **Spanish**: Cimerillo de Casquete
German: Helm-Schuppenkopftyrann

Taxonomy. *Motacilla Galeata* Boddaert, 1783, Cayenne, French Guiana.
Formerly placed in a monotypic genus, *Colopteryx*, on grounds of narrow outer three primaries, but subsequently moved to present genus owing to overwhelming similarities (including anatomical characters) to current congeners. Monotypic.
Distribution. E Venezuela (Sucre, Monagas, Bolívar, Amazonas), the Guianas, E Colombia, NE Peru (Loreto) and N Brazil (N Amazonas E to Amapá and, S of Amazon, E from R Tapajós to Maranhão).
Descriptive notes. 10·2 cm; 6-7 g. Has long black crown feathers with greyish-olive edging, forming crest (sometimes erected and fanned), whitish lores; upperparts olive; wings dusky, two very indistinct olive wingbars and narrow edgings, outer three primaries shortened and narrow; tail dusky with olive edge; throat and underparts whitish, indistinctly streaked grey; iris yellowish to orangish-white; bill grey, pink base of lower mandible; legs flesh-coloured. Differs from similar *L. vitiosus* in having crown feathers narrower and more elongate, making crest less conspicuous, longer tail. Sexes alike. Juvenile undescribed. Voice. Series of 4-10 dry staccato "pik" or "trik" notes, sometimes ending in warbled or trilled phrase, pattern very similar to that of *L. pileatus* but voice not nearly so loud; sometimes sings constantly throughout heat of day.

Habitat. *Terra firme* and *várzea* forest and edge, also second growth and swampy or tall savanna woodland; also dry scrub on white sandy soils. To 1100 m. Most numerous in slightly drier, more scrubby white-sand forest (e.g. in Venezuela).
Food and Feeding. Insects. Forages usually alone, sometimes with mixed-species flocks, in mid-storey of forest; makes short sallies to strike at insects from underside of foliage, without hovering.
Breeding. Eggs in Mar and nestlings in late Sept in Surinam; birds in breeding condition in Feb-Apr in Venezuela. Bag-like domed nest with lateral entrance near bottom, small awning projecting above entrance, suspended from tree branch c. 2-10 m above ground. Clutch 2 or 3 eggs; chicks fed by both parents; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common. Occurs in Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, and Tapajós National Park, Rio Cristalino Forest Reserve and EMBRAPA Experimental Station, all in Brazil. Given that much of this species' habitat remains in relatively pristine condition within its range, it is not believed to be at any immediate risk. Only very recently discovered to occur in NE Peru.
Bibliography. Álvarez & Whitney (2003), Bangs & Penard (1918), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Friedmann (1948), Gilliard (1941), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Novaes (1978a), Oren & Parker (1997), Payne (1984), Penard & Penard (1910), Peres & Whittaker (1991), Ridgely & Tudor (1994), Schönwetter & Meise (1968), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977), Willard *et al.* (1991).



Genus *ATALOTRICCUS* Ridgway, 1905

144. **Pale-eyed Pygmy-tyrant**

Atalotriccus pilaris

French: Microtyran coiffé **German**: Blassaugen-Zwergtyrann **Spanish**: Mosquerito Ojiblanco
Other common names: White-eyed Pygmy-tyrant

Taxonomy. *C[olopterus] pilaris* Cabanis, 1847, Cartagena, Bolívar, Colombia.
Closely related to, and sometimes placed in, genus *Lophotriccus*, despite lack of a distinctive crown pattern. Race *venezuelensis* only marginally distinct from nominate, perhaps better subsumed in latter. Four subspecies recognized.
Subspecies and Distribution.
A. p. wilcoxi Griscom, 1924 - W Panama (Chiriquí E to Canal Zone).
A. p. pilaris (Cabanis, 1847) - N Colombia (Bolívar E to Guajira, S to Huila and Meta) and NW Venezuela (Zulia, Táchira).
A. p. venezuelensis Ridgway, 1906 - N Venezuela from Carabobo E to Sucre, and in *llanos* from W Apure E to Monagas.
A. p. griseiceps (Hellmayr, 1911) - E Colombia, EC Venezuela (N Amazonas, N Bolívar, Delta Amacuro) and W Guyana.

Descriptive notes. 9·7 cm; 6 g. Nominate race is olive above, head side buffy, lores whitish; wings dusky, two yellow wingbars, flight-feathers narrowly edged yellow, outer four primaries greatly reduced, shortened and narrow; tail dusky; throat and underparts whitish, streaked brown, flanks and crissum washed yellow; iris pale yellow-white, narrow buffy eyering; bill small, grey, pinkish base of lower mandible; legs flesh-coloured. Sexes similar, female has primaries slightly less reduced than male's. Juvenile has dark iris. Race *wilcoxi* is very like nominate, but upperparts slightly duller green, wing markings less distinct, underparts paler yellow; *venezuelensis* differs marginally from nominate, has crown greyer, back fresher green; *griseiceps* has smoky grey crown contrasting strongly with green of back (green duller than previous), orbital region and forehead tinged cinnamon buff. Voice. Very loud for size of bird; dry "tic" notes alone, or sometimes combined with trills as "tic-trrrrrrrrrr", "tic-tic trrrr" or "tic-tic-t-tr-tr-r-rreep", reminiscent of *Lophotriccus pileatus* in quality and pattern.
Habitat. Drier scrub-woodland, thickets, open woodland, also moister deciduous and semi-deciduous woodland, gallery forest; to 800 m, occasionally to 2000 m.
Food and Feeding. Insects. Forages alone or in pairs, sometimes with mixed-species flocks, low in dense vegetation. Makes short upward strikes (73% of foraging manoeuvres) or downward strikes (17%) to glean prey from leaves.
Breeding. Nests found in Jun-Jul in Venezuela; adults in breeding condition or young fledglings virtually throughout year. Often makes audible buzzing sound with rapid wing vibrations, presumably enhanced by modified outer primaries, perhaps as display. Hanging nest 0·3 m long, side entrance with small awning, made of fibres, often close to ground. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common; generally common in Venezuela. Reports from extreme N Brazil (around R Cotingo and R Urucury, in N Roraima) require confirmation. Species is fairly adaptable, able to thrive in secondary and other disturbed habitats.
Bibliography. Anon. (1998a), Blake (1962), Chapman (1917c), Cory & Hellmayr (1927), Eisenmann (1955), Fitzpatrick (1980c, 1981, 1985b), Friedmann & Smith (1950), Haffer (1975), Hilty (2003), Hilty & Brown (1986), McLellan (1938), Meyer de Schauensee (1982), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Snyder (1966), Stotz *et al.* (1996), Strewe & Navarro (2003), Traylor (1977), Traylor & Fitzpatrick (1982), Wetmore (1939, 1972), Willis (2003).

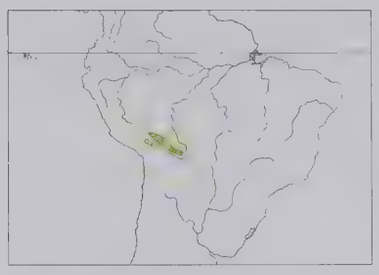
Genus *HEMITRICCUS* Cabanis & Heine, 1859

145. **Snethlage's Tody-tyrant**

Hemitriccus minor

French: Todirostre de Snethlage **German**: Kleintodityrann **Spanish**: Titirijí de Snethlage
Other common names: Lesser Tody-Tyrant

Taxonomy. *Euscarthmus zosterops minor* E. Snethlage, 1907, Arumateua, left bank, lower River Tocantins, central Pará, Brazil.
Formerly treated in a monotypic genus, *Snethlagea*, on basis of unusual nostril and bill shapes; these features, however, shared with *H. spodiops*, and some authors propose re-establishment of that genus, containing these two species. Previously considered conspecific with *H. minimus*. Race *pallens* possibly a separate species; specimens allegedly of this race from S Venezuela (Amazonas) require re-examination in light of recent significant taxonomic clarifications in this and related species. Nominate race and *snethlageae* difficult to differentiate, intergrade in C Amazonian Brazil (Pará); possibly better merged. Three subspecies recognized.
Subspecies and Distribution.
H. m. pallens (Todd, 1925) - WC Brazil on both sides of Amazon, from Amazonas (very near Peruvian border) E to W banks of R Negro and R Madeira.
H. m. snethlageae (E. H. Snethlage, 1937) - C Amazonian Brazil (from right bank of R Madeira E to right bank of R Tapajós, S to N Rondônia and NW Mato Grosso) and NE Bolivia (E Beni, Santa Cruz).
H. m. minor (E. Snethlage, 1907) - E Amazonian Brazil in C Pará (vicinity of lower R Xingú and R Tocantins).



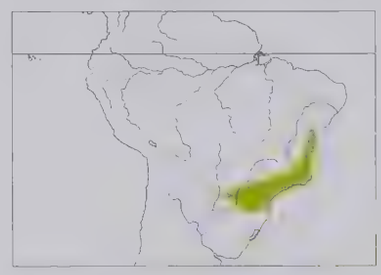
Descriptive notes. 10 cm; 7-7·9 g. Bill quite wide at base, with unusually large, rounded nostrils. Nominate race has crown and upperparts olive-green, crown feathers somewhat elongated (forming short bushy crest); wings and tail olive, two yellowish wingbars, greenish-yellow edges of remiges; throat and underparts pale yellow with indistinct greyish-olive streaking, centre of belly unstreaked; some individuals with all-white underparts; iris white to pale yellow; bill brown to blackish, lower mandible pinkish at base; legs grey to pinkish-grey. Distinguished from very similar *H. zosterops* by darker lores, less distinct wingbars, longer crown feathers, unusual nostrils. Female slightly brighter above and yellower below. Race *pallens* has underparts paler than nominate, wingbars more distinct; *snethlageae* is smaller overall, with tail shorter, wingbars yellower and more distinct, underparts brighter yellow. VOICE. Several variants of rapid, gravelly, nasal trills (similar to *Lophotriccus vitiosus*) often followed by series of "tic" notes; one variant (nominate race and *snethlageae*) with 35-75 notes delivered extremely rapidly (duration less than 1 second) all on one pitch, sounding more like a buzz than a trill, and given singly; another variant (*pallens*) has fewer notes (14-30) delivered slightly more slowly, and often in bouts of three or four songs in rapid succession; also, individual "tic" notes as a call.
Habitat. Tropical evergreen forest, mostly *terra firme* and tall second growth (nominate and *snethlageae*), or *igapó* (*pallens*); found especially in vine tangles and dense vegetation at edges and treefall gaps.
Food and Feeding. Insects. Forages singly or in pairs, 3-8 m above ground in dense vegetation; makes short upward strikes to glean prey from underside of leaves.
Breeding. No published information. Nest reported as being pendent, in style typical of other members of the genus.
Movements. Resident.
Status and Conservation. Not globally threatened. Locally fairly common to common. Occurs in Anavilhanas Ecological Station and Jaú National Park, in Brazil, and Noel Kempff Mercado National Park, in Bolivia.
Bibliography. Bates & Parker (1998), Bencke *et al.* (2001), Cohn-Haft (1996, 2000), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Cracraft (1985), Forrester (1993), Hilty (2003), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Parker *et al.* (1991), Remsen & Traylor (1989), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz (1992), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977), Zimmer (1940a).

146. **Yungas Tody-tyrant**

Hemitriccus spodiops

French: Todirostre de Bolivie **German**: Yungastodityrann **Spanish**: Titirijí Boliviano
Other common names: Grey-faced Tody-Tyrant

Taxonomy. *Euscarthmus spodiops* Berlepsch, 1901, Yungas of La Paz, western Bolivia.
Formerly treated in now defunct genus *Idioptilon*. Considered closely allied to *H. minor*; the two share unusual nostril and bill shapes, and thought by some authors possibly to merit separate generic rank via resurrection of genus *Snethlagea*. Monotypic.
Distribution. C Bolivia (La Paz, Cochabamba, W Santa Cruz).
Descriptive notes. 11 cm; 6·9-7·5 g. Bill quite broad-based, with unusually large, rounded nostrils. Crown and upperparts are dark olive-green, crown with elongated feathers forming short crest; lores greyish-buff; wings with two indistinct yellowish-olive wingbars; throat and breast greyish-olive with indistinct whitish streaking, lower belly clear yellowish-white; iris pale yellow; bill blackish; legs fleshy grey to flesh-coloured. Sexes alike. VOICE. Long, very fast, harsh trill dropping slightly in pitch throughout, usually given in bouts of 2-4 trills in rapid succession; much more reminiscent of *Lophotriccus pileatus* than of congeners.



Habitat. Humid lower montane forest, bamboo, shrubby forest borders, tall second growth along roads and landslides; 800-1600 m, occasionally to 2450 m.
Food and Feeding. Insects. Forages alone, low in dense vegetation, usually only 1-3 m above ground; makes short upward strikes to glean prey from undersides of leaves.
Breeding. No documented information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Bolivian and Peruvian Lower Yungas EBA. Uncommon to locally common. At least 5 individuals/km of road recorded in Serranía Pilón, and 4 individuals/km of road at Calabatea (La Paz). Occurs in Pilón Lajas Biosphere Reserve and Madidi National Park. Forests in lower Yungas of Peru and Bolivia have been extensively converted for cultivation, especially cash crops such as coca and coffee. This species is, however, found in all protected areas in the Yungas of La Paz and Cochabamba.
Bibliography. Cohn-Haft (1996, 2000), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Green (1997a), Hennessey, Herzog, Kessler & Robinson (2003), Hennessey, Herzog & Sagot (2003), Lowen *et al.* (1995), Meyer de Schauensee (1982), Parker *et al.* (1991), Remsen & Traylor (1989), Remsen *et al.* (1982), Ridgely & Tudor (1994), Stotz *et al.* (1996), Traylor (1977).

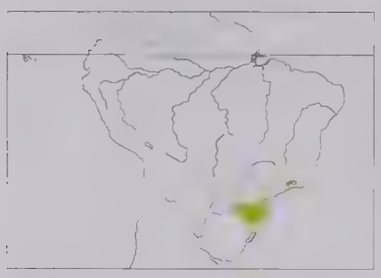
147. **Drab-breasted Pygmy-tyrant**

Hemitriccus diops

French: Todirostre à poitrine ombrée **German**: Weißstern-Todityrann **Spanish**: Titirijí Pechigrís
Other common names: Drab-breasted Bamboo-tyrant

Taxonomy. *Muscicapa diops* Temminck, 1822, Ipanema, São Paulo, Brazil.
Formerly included *H. obsoletus* and *H. flammulatus* as races. Monotypic.
Distribution. CE & SE Brazil (Bahia S to São Paulo, Paraná and N Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).

Descriptive notes. 11 cm; 9·5-13·5 g. Has crown and upperparts plain dark olive-green; supraloral spot and conspicuous eyering white; wings and tail plain olive, sometimes paler border on innermost secondaries; throat and breast dull grey, tinged purplish or pinkish, with indistinct white crescent at centre of lower throat; belly clear whitish, crissum tinged yellow; iris reddish-brown; upper mandible grey, lower mandible pinkish; legs light grey. Sexes alike. VOICE. Short dry trill, sometimes doubled, "tr-r-r-r, tr-r-r-r"; also "bit", "sewit" or "bit-biwít", somewhat similar to calls of *Platyrinchus mystaceus*.
Habitat. Mature humid forest and second growth, especially in bamboo patches at edges or in understorey mixed with bamboo; to 1300 m.
Food and Feeding. Diet consists of insects. Forages alone or in pairs, generally in thick undergrowth, rarely with mixed-species flocks; makes short upward sallies to vegetation in order to glean prey.
Breeding. Nest purse-shaped and pendent, with side entrance, suspended from end of twig; nest parasitism by Pavonine Cuckoo (*Dromococcyx pavoninus*) reported. No other information available.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Common at Estancia Itabó Private Nature Reserve (Canindeyú), in Paraguay, and fairly common in Itatiaia and Serra dos Órgãos National Parks, in Brazil. Occurs also in Augusto Ruschi Biological Reserve, Patrimônio Natural do Caraça Special Reserve and Iguaçu and Tijuca National Parks, all in Brazil, and Caaguazú and San Rafael National Parks, in Paraguay.
Bibliography. Bauer & Pacheco (2000), Belton (1985), Bencke *et al.* (2001), Brooks *et al.* (1993), Canevari *et al.* (1991), Cory & Hellmayr (1927), Cracraft (1985), Develey (2004), Ferreira de Vasconcelos (2001), Ferreira de Vasconcelos & Melo-Júnior (2001), Hayes (1995), Ihering (1904), Lowen *et al.* (1996), Meyer de Schauensee (1982), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Neunteufel (1951), Pacheco & Whitney (1995), de la Peña (1988), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Venturini *et al.* (2001).



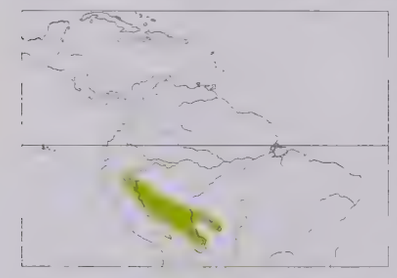
148. **Brown-breasted Pygmy-tyrant**

Hemitriccus obsoletus

French: Todirostre à poitrine brune **Spanish**: Titirijí Pechipardo
German: Braunbrust-Todityrann
Other common names: Brown-breasted Bamboo-tyrant

Taxonomy. *Musciphaga obsoleta* Miranda-Ribeiro, 1906, Itatiaia, Rio de Janeiro, Brazil.
Formerly considered conspecific with *H. diops*. Race *zimmeri* initially named as *naumburgae*, but that name preoccupied when genus was enlarged. Two subspecies recognized.
Subspecies and Distribution.
H. o. obsoletus (Miranda-Ribeiro, 1906) - SE Brazil, in W Rio de Janeiro (Serra do Itatiaia) and E São Paulo (Serra Bocaina and Serra Bananal).
H. o. zimmeri Traylor, 1979 - SE Brazil, in Paraná and Rio Grande do Sul, and extreme NE Argentina (Iguazú National Park).

On following pages: 149. Flammulated Pygmy-tyrant (*Hemitriccus flammulatus*); 150. Boat-billed Tody-tyrant (*Hemitriccus josephinae*); 151. White-eyed Tody-tyrant (*Hemitriccus zosterops*); 152. White-bellied Tody-tyrant (*Hemitriccus griseipectus*); 153. Eye-ringed Tody-tyrant (*Hemitriccus orbitatus*); 154. Johannes's Pygmy-tyrant (*Hemitriccus iohannis*); 155. Stripe-necked Tody-tyrant (*Hemitriccus striaticollis*); 156. Hangnest Tody-tyrant (*Hemitriccus nidipendulus*); 157. Pearly-vented Tody-Tyrant (*Hemitriccus margaritaceiventer*); 158. Pelzeln's Tody-tyrant (*Hemitriccus inornatus*); 159. Zimmer's Tody-tyrant (*Hemitriccus minimus*).



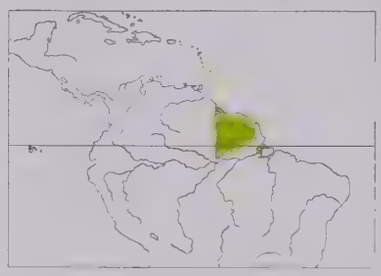
Descriptive notes. 11 cm; 9-11 g. Nominate race has crown and upperparts plain brownish-olive, supraloral buffy, forming distinct spot in front of eye, eyering pale buffy, side of head brownish; wings plain brownish-olive, tail dusky; throat and breast dingy buff, with indistinct buffy crescent around lower throat, belly clear buffy ochraceous, crissum tinged buffy yellow; iris reddish-brown; upper mandible grey, lower mandible pinkish; legs light grey. Sexes alike. Race *zimmeri* has upperparts more greenish than nominate, with breast and sides tinged slightly more ochraceous, belly and crissum more strongly ochraceous. Voice. Sharp, fast staccato notes, "tic-tic-tic, tic", slower and with each note more distinct than in the case of *H. diops*; also makes a buzzy "brrrrrr", created by wings.
Habitat. Mature humid tropical forest and older second growth, especially in bamboo patches; 500-2300 m, but usually replaced by *H. diops* below 1200 m.
Food and Feeding. Insects. Forages alone or in pairs in shady undergrowth, especially in bamboo thickets, usually only 1-3 m above ground; makes short upward strikes to glean prey from undersides of leaves.
Breeding. Nov-Dec in Rio Grande do Sul (SE Brazil). Nest unusual for genus, a globular ball 17·5 cm high and 16 cm wide, dome-shaped roof and deep inner cup (8 cm across and 7 cm deep), rounded side entrance shaded by small "visor" and with several bamboo leaves projecting from entrance, roof composed mainly of green moss and filamentous *Tillandsia* leaves, also black *Marasmius* fungal rhizomorphs, internal cup composed of bamboo leaves and plant down; attached to several vertical stalks of *Chusquea* bamboo c. 0·5 m above ground in dense bamboo thicket beneath mature forest. Clutch 2 eggs; no information available on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Atlantic Forest Mountains EBA. Uncommon to fairly common. Fairly common in N Rio Grande do Sul, Mata dos Godoy State Park (Paraná) and Itatiaia National Park, all in Brazil; found also in Iguazú National Park, in Argentina. Montane forests have suffered less destruction than have adjacent lowland areas, but isolated patches in N of this species' range have virtually disappeared owing to expansion of pasture and cultivation.
Bibliography. Bauer & Pacheco (2000), Belton (1985), Bencke *et al.* (2001), Buzzetti (2000), Cory & Hellmayr (1927), Cracraft (1985), Forrester (1993), Meyer de Schauensee (1982), Ridgely & Tudor (1994), do Rosário (1996), Saibene & Castelino (1993), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977).

149. Flammulated Pygmy-tyrant

Hemitriccus flammulatus

French: Todirostre flammulé **German**: Streifenbrust-Todityrann **Spanish**: Titirijí Flamulado
Other common names: Flammulated Bamboo-tyrant

Taxonomy. *Hemitriccus flammulatus* Berlepsch, 1901, San Mateo, Yungas of Cochabamba, Bolivia.
Formerly considered conspecific with *H. diops*. Two subspecies recognized.
Subspecies and Distribution.
H. f. flammulatus Berlepsch, 1901 - E Peru (San Martín S to Madre de Dios), NW Brazil (Acre, and R Mequéns in Rondônia) and N Bolivia (E to E Beni, S to Cochabamba).
H. f. olivascens (Todd, 1915) - E Bolivia (R Surutú, in Santa Cruz).



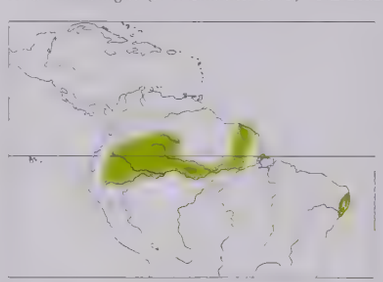
Descriptive notes. 11 cm; 8·8-11·7 g. Nominate race has crown and upperparts plain olive-green, dull whitish to buff-white supraloral spot and narrow eyering; wings and tail plain olive; throat whitish, streaked brownish-grey; breast buffy brown with pinkish tinge, belly clear white; iris reddish-brown to pale yellow; upper mandible dark grey to blackish, lower mandible pale pinkish-grey to white; legs light grey. Sexes alike. Race *olivascens* has upperparts more yellowish-olive, flanks and crissum tinged pale greenish-yellow. Voice. Sharp "tic" notes and fast rising trill, "tik-trrrrrríp", remarkably similar in tone to, but shorter than, trilled notes of *Poecilotriccus albifacies*, which occurs in same habitat.
Habitat. Mature, humid *terra firme* and dense second growth; almost always associated with *Guadua* bamboo, often found in large, pure bamboo stands. Mostly below 500 m, occasionally to 1300 m.
Food and Feeding. Arthropods. Stomach contents in SE Peru contained 19 prey items, of which beetles (Coleoptera) 33%, hemipterans 18%, homopteran bugs (planthoppers) 16%, lepidopteran larvae 16%, ants (Hymenoptera) 5%, spiders (Araneae) 5%, other 7%. Usually in pairs; rarely follows mixed-species flocks. Forages in undergrowth and middle storey of forest, favouring thick areas mixed with bamboo, and in leafy upper storey of mature bamboo stands; makes short upward sally-strikes against vegetation to glean prey.
Breeding. Birds with enlarged gonads in Aug-Nov in SE Peru. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common but local. Fairly common in Tambopata-Candamo Reserved Zone and Manu National Park and Biosphere Reserve, in Peru; and Beni and Pilón Lajas Biosphere Reserves and Madidi and Noel Kempff Mercado National Parks, all in Bolivia.
Bibliography. Allen (1995), Angehr & Aucca (1997), Bates & Parker (1998), Begazo (1995), Clements & Shany (2001), Cory & Hellmayr (1927), Forrester (1993), Hennessey, Herzog & Sagot (2003), Kratter (1997), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977), Zimmer (1940a).

150. Boat-billed Tody-tyrant

Hemitriccus josephinae

French: Todirostre de Joséphine **German**: Grauwangen-Todityrann **Spanish**: Titirijí de Josefina
Other common names: Josephine's Tody-tyrant

Taxonomy. *Euscarthmus josephinae* Chubb, 1914, Supenaam, west bank of Essequibo River, Guyana.
Formerly treated in a monotypic genus, *Microcochlearius*, because of rounded tail and unusually wide bill. Relationships within present genus remain unclear. Monotypic.
Distribution. The Guianas and NC Brazil (S to Manaus, and E to Amapá); probably also extends to S & E Venezuela.



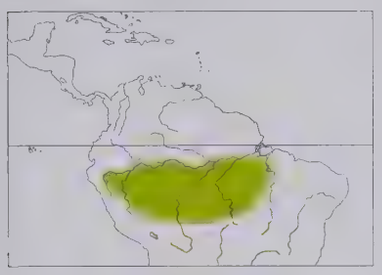
Descriptive notes. 11 cm; 10·2-10·8 g. Has crown and upperparts uniform dull olive, lores and auriculars pale grey; wings plain olive, tail dusky brownish-olive; throat dingy greyish-white, breast and belly clear pale yellow, crissum somewhat buffy; iris reddish-brown; bill grey, pale base of lower mandible; legs light grey. Sexes alike. Voice. Dry, descending "pic-pic-pic".
Habitat. Poorly known; normally encountered in humid tropical evergreen forest, most typically in vine tangles, treefall gaps and forest edge.
Food and Feeding. Probably insects. Alone or in pairs; sometimes joins mixed-species flocks. Forages in dense areas within middle storey of forest, mostly at 6-9 m, pausing for long periods; makes short upward sallies to vegetation to glean prey from foliage and branches.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally rare. Occurs in Raleigh Falls-Voltzberg National Park and Sipaliwini Savanna Nature Reserve, both in Surinam. Poorly known.
Bibliography. Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), Donahue (1985), Forrester (1993), Haverschmidt & Mees (1994), Hilty (2003), Meyer de Schauensee (1982), Novaes (1978a), Ridgely & Tudor (1994), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1977).

151. White-eyed Tody-tyrant

Hemitriccus zosterops

French: Todirostre zostérops **German**: Weißaugen-Todityrann **Spanish**: Titirijí Ojiblanco

Taxonomy. *Euscarthmus Zosterops* Pelzeln, 1868, Marabitanas, Rio Negro, Brazil.
Formerly placed in genus *Euscarthmornis* and, more recently, *Idioptilon*, both now defunct. Was for long treated as conspecific with *H. griseipectus*, but the two exhibit major differences in plumage and voice; vocal characters suggest that geographically isolated race *naumburgae* may belong with that species. E Amazonian populations vocally distinct from those W of R Branco and R Negro, suggesting that two distinct species may be involved; birds from French Guiana described as race *rothschildi*, and that name (currently synonymized with nominate) would be available for E form, if found to be a separate species. Boundary between nominate race and *flaviviridis* uncertain, as vocal type of former occurs only E of R Branco and R Negro, in N Brazil, and that of latter extends E to those rivers; has been proposed by some authors that the two races be merged. Three subspecies recognized.
Subspecies and Distribution.
H. z. zosterops (Pelzeln, 1868) - SE Colombia (Caquetá, Vaupés), E Ecuador and NE Peru (Loreto) through S Venezuela (S Amazonas) and much of Brazil N of Amazon (Amazonas, NW Pará, Amapá) to E Surinam and French Guiana.
H. z. flaviviridis (J. T. Zimmer, 1940) - N Peru (C Amazonas, N San Martín).
H. z. naumburgae (J. T. Zimmer, 1945) - NE Brazil (Rio Grande do Norte S to Alagoas).



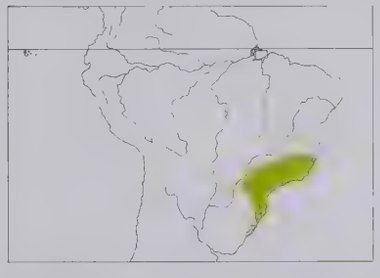
Descriptive notes. 11 cm; 7·8-10 g. Nominate race has crown and upperparts olive-green, supraloral area whitish, indistinct white eyering; wings dusky, two fairly distinct yellowish wingbars, bright olive-yellow edges of remiges; tail dusky olive; throat grey, streaked dusky, breast and flanks olive, flammulated yellow, belly clear pale yellow; iris pale grey or straw-yellow (sometimes reddish-brown); bill black, base of lower mandible pinkish; legs dark grey. Sexes similar. Race *flaviviridis* is brighter than nominate, more yellowish-green above, underparts with stronger yellow flammulation (presenting greener, less grey, tinge); *naumburgae* has upperparts paler, yellower green, belly whitish. Voice. Nominate race song type a dry 1-second trill, rising and then falling slightly in pitch, slowing towards end, and immediately preceded by distinct single note (very similar to songs of *H. minor* and *Lophotriccus*, but with initial distinct note and gradually slowing during trill); *flaviviridis* an insect-like, staccato series of 5-11 notes with metallic tonal quality and on same pitch, sometimes introduced or concluded by separate, distinctly higher note, "pik, pik-pik-pik-pik"; *naumburgae* primary song "kwidíp" or "kwididíp", similar to that of *H. griseipectus*.
Habitat. Occupies humid *terra firme* forest, especially in hilly terrain and foothills; recorded up to 850 m.
Food and Feeding. Usually solitary, occasionally in pairs; only occasionally follows mixed-species flocks. Perches inconspicuously, but often on very open perches in lower and middle growth of forest below canopy; makes short upward strikes to glean prey from undersides of leaves.
Breeding. No published information. Nest reported as being pendent.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Fairly common in Serranías Cofán (Sucumbíos), in Ecuador; occurs also in Jaú National Park, in Brazil. Isolated NE Brazilian race *naumburgae* is poorly known; present in Mata Estrela Private Reserve (Rio Grande do Norte), Murici Ecological Reserve (Alagoas) and Pedra Branca/Fazenda Bananeira Reserve (Alagoas).
Bibliography. Bencke *et al.* (2001), Chapman (1917c), Clements & Shany (2001), Cohn-Haft (1996, 2000), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Friedmann (1948), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1982), Novaes (1978a), Peres & Whittaker (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (2001), Sick (1993, 1997), Silveira *et al.* (2003), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992), Traylor (1977), Willard *et al.* (1991), Zimmer (1940a).

152. White-bellied Tody-tyrant

Hemitriccus griseipectus

French: Todirostre à ventre blanc **Spanish**: Titirijí Ventriblanco
German: Weißbauch-Todityrann

Taxonomy. *Euscarthmus griseipectus* E. Snethlage, 1907, Alcobaça, River Tocantins, Brazil.
Has often been considered conspecific with *H. zosterops*, but the two show major differences in plumage and voice; vocal characters suggest that race *naumburgae* of that species may belong with present species. Monotypic.
Distribution. C Brazil S of Amazon (C Amazonas E to R Tocantins) S to SE Peru (Cuzco, N Puno) and N Bolivia (Pando, La Paz, Beni).



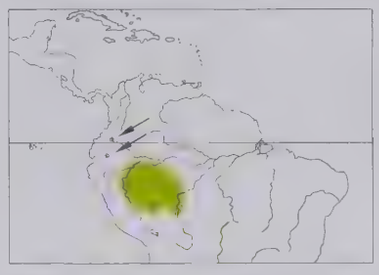
Descriptive notes. 11 cm; 7·9-10 g. Has crown and upperparts olive-green, loral area pale, indistinct whitish eyering; wings dusky, two fairly distinct yellowish wingbars, olive-yellow edgings; throat greyish-white, streaked dusky, breast greyish, belly clear whitish; iris white, very pale grey, or straw-yellow; bill black, base of lower mandible pinkish; legs grey to dark grey. Sexes alike. Voice. Rising couplet or triplet of nasal to metallic notes, rapid and high-pitched, "ca-déék" or "kee-dee-deek", given at intervals from 2-3 seconds to 30 seconds.
Habitat. Humid tropical *terra firme* and transitional forest in low country, hills and base of foothills.
Food and Feeding. Insects. Forages alone, more rarely in pairs, very rarely joining mixed-species flocks. Perches inconspicuously, but usually on quite open perches well below canopy, 10-20 m above ground; pauses 30-60 seconds on each perch, making short upward sallies to underside of vegetation to glean prey.
Breeding. Birds with enlarged gonads in Sept-Oct in SE Peru. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Common in Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru; also occurs in Beni and Pilón Lajas Biosphere Reserves and Madidi National Park, all in Bolivia.
Bibliography. Allen (1995), Clements & Shany (2001), Cohn-Haft (2000), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Forrester (1993), Gyldenstolpe (1950), Hennessey, Herzog, Kessler & Robinson (2003), Hennessey, Herzog & Sagot (2003), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schubart *et al.* (1965), Stotz *et al.* (1996), Traylor (1977), Zimmer (1940a).

153. Eye-ringed Tody-tyrant

Hemitriccus orbitatus

French: Todirostre à lunettes **German**: Augenring-Todityrann **Spanish**: Titirijí de Anteojos
Other common names: Olivaceous Tody-tyrant

Taxonomy. *E[uscarthmus] orbitatus* Wied, 1831, River Doce, Espírito Santo, Brazil.
Formerly treated in genus *Euscarthmornis* and later in *Idioptilon*, both now defunct. Monotypic.
Distribution. SE Brazil, from E Minas Gerais and Espírito Santo S to Rio Grande do Sul.



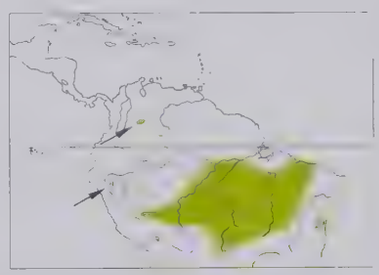
Descriptive notes. 11·5 cm; 9-10·5 g. Has crown and upperparts plain dark olive, prominent white supraloral spot and wide white eyering; wings olive, prominent white border on outer webs of innermost remiges; tail dusky olive; throat greyish-white, breast washed olive, both streaked with darker olive, rest of underparts yellow; iris dark brown; upper mandible grey, lower mandible pale; legs light grey. Sexes alike. Voice. Rapid squeaky trill, "tr-r-r-r-r-r-r-r-r", or "tirrit, tirritit".
Habitat. Humid forest and second growth, from near sea-level to 600 m, infrequently to 1000 m.
Food and Feeding. Insects. Forages alone or in pairs in lower and middle growth of forest, most often in interior away from forest edge. Perches vertically on exposed branches under canopy; makes short upward strikes to glean prey from undersides of leaves.
Breeding. Few data. No published description of nest, but reported as usually building hanging purse with side entrance, typical of genus, also (one of four nests) a non-hanging ball-shaped nest. Clutch 2 eggs.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Locally uncommon to fairly common. Common at lower elevations in Serra dos Órgãos (Rio de Janeiro) and common at Patrimônio Natural de Volta Velha Special Reserve, near Itapoá (Santa Catarina); fairly common in N Rio Grande do Sul, but rare at Saibadela Research Station (in Intervales State Park); occurs also at Salto do Piraí (Santa Catarina), Serra Paranapiacaba International Biosphere Reserve and Tijuca National Park. Deforestation, agricultural conversion, mining, urbanization and industrialization, with associated road-building, have left less than 20% of original Atlantic Forest intact; remaining lowland forests continue to be cleared.
Bibliography. Aleixo & Galetti (1997), Belton (1985), Bencke *et al.* (2001), Buzzetti (2000), Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), Develey (2004), Forrester (1993), Meyer de Schauensee (1982), Parker *et al.* (1996), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993), Traylor (1977).

154. Johannes's Pygmy-tyrant

Hemitriccus iohannis

French: Todirostre de Johannes **German**: Braunzügel-Todityrann **Spanish**: Titirijí de Johannes
Other common names: Johannes's Tody-tyrant

Taxonomy. *Euscarthmus iohannis* E. Snethlage, 1907, Monte Verde, River Purús, Brazil.
Formerly treated in genus *Euscarthmornis* and later in *Idioptilon*, both now defunct. Was considered conspecific with *H. striaticollis*, but the two occur sympatrically at several localities in Peru and Bolivia. Monotypic.
Distribution. SW Amazonia in E Peru (S to Madre de Dios), W Brazil (E to upper R Solimões, R Juruá and R Purus) and N Bolivia (Pando, Beni); also isolated localities in S Colombia (Putumayo) and E Ecuador (Kapawi), and probably more widespread.



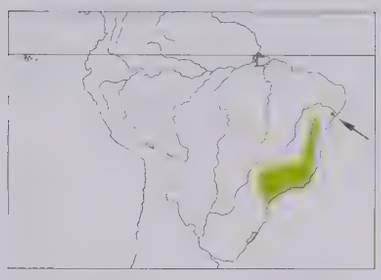
Descriptive notes. 11 cm; 9·2-12·7 g. Crown and upperparts are uniform bright olive, lores and ocular area brownish, sometimes with white supraloral spot; wings dusky olive, indistinct yellow edges of remiges, two indistinct yellow wingbars; throat whitish with very fine black streaks, underparts pale yellow with blurry streaking, breast side and flanks smudged olive; iris whitish to pale straw-yellow; bill dark grey to blackish; legs pale yellowish, pinkish or light grey. Sexes alike. Voice. Distinctive, fast staccato trill with separate introductory note, "tik-trrrrrrrrrrrrrrrrree", rising at end.
Habitat. Humid tropical secondary growth and, especially, riparian woodland and brush, usually in vine tangles or dense shrubby growth; also in mature river-edge cane interspersed with vines and leafy saplings. Up to 600 m.
Food and Feeding. Arthropods. Stomach contents in SE Peru contained 35 prey items, of which hymenopterans 32% (ants 29%, wasps 3%), homopteran bugs (planthoppers) 29%, coleopterans 26%, orthopterans 6%, true bugs (Hemiptera) 3%, spiders (Araneae) 3%. Forages alone, in pairs, or in small family groups; typically, does not follow mixed-species flocks. Perches in middle and upper growth of dense brushy growth and vine thickets; makes short upward strikes to glean prey from undersides of leaves.
Breeding. Birds with enlarged gonads late Jul to late Oct in SE Peru. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Considered to be rare to locally fairly common. Fairly common at Amazonia Lodge (Cuzco), in Peru, where also occurs in Manu National Park and Biosphere Reserve, Pacaya-Samiria National Reserve and Tambopata-Candamo Reserved Zone. Also found in Kapawi Ecological Reserve, in Ecuador, and in Madidi National Park, in Bolivia.
Bibliography. Allen (1995), Begazo (1995), Begazo & Valqui (1998), Clements & Shany (2001), Cory & Hellmayr (1927), Gyldenstolpe (1950), Hennessey, Herzog & Sagot (2003), Hilty & Brown (1986), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Schulenberg *et al.* (2001), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1958, 1977, 1982), Zimmer (1940a).

155. Stripe-necked Tody-tyrant

Hemitriccus striaticollis

French: Todirostre à cou rayé **German**: Streifenkehl-Todityrann **Spanish**: Titirijí Gorgiestriado

Taxonomy. *Todirostrum striaticolle* Lafresnaye, 1853, Bahia, Brazil.
Formerly treated in genus *Euscarthmornis* and later in *Idioptilon*, both now defunct. Was considered conspecific with *H. iohannis*, but the two occur sympatrically at several localities in Peru and Bolivia. Validity of race *griseiceps* doubtful. Birds from N Peru and C Brazil (Mato Grosso), supposedly with darker crown and more olive wash on breast side, described as a third race, *obscuriceps*; considered indistinguishable from nominate because of range of individual variation in latter. Two subspecies recognized.
Subspecies and Distribution.
H. s. striaticollis (Lafresnaye, 1853) - E Colombia (Meta); N Peru (San Martín); and from S Peru (Cuzco, Madre de Dios) and N Bolivia (Beni) to C & E Brazil (upper R Madeira E to Maranhão, and S to Mato Grosso, Goiás and Minas Gerais; E Bahia).
H. s. griseiceps (Todd, 1925) - E Amazonian Brazil in W Pará (lower R Tapajós).



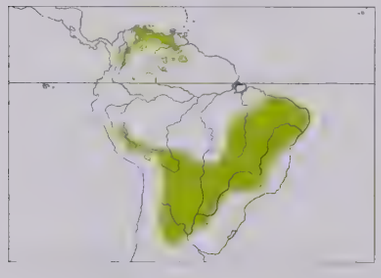
Descriptive notes. 11 cm; 7·8-11 g. Nominate race has greyish-brown crown contrasting with olive upperparts; large white supraloral spot and white eyering; wings plain olive, indistinct yellow edges of remiges; tail dusky olive; throat white with sharp, distinct brownish streaks, streaks continuing onto breast, underparts bright yellow, tinged greenish and diffusely streaked on flanks; iris whitish to pale yellow; bill blackish, paler near base of lower mandible; legs light grey. Sexes similar. Juvenile has darker iris. Race *griseiceps* has upperparts duller green and crown more pure grey than nominate. Voice. Fast "pit-pit-pit-pit, whi-didit" or "bewet-bewit béé-bibit", sometimes without introductory "pit" notes.
Habitat. Mainly found in humid to semi-humid secondary woodland and riparian growth, low thickets, and bamboo, most often in semi-open country; recorded up to 700 m, occasionally to 1000 m.
Food and Feeding. Insects. Forages alone or in pairs in dense middle and upper growth of low-stature forest, shrubby edges, vine tangles, and bamboo; makes short upward strikes to glean prey from undersides of leaves.
Breeding. Nest not described; clutch 2 eggs. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally uncommon to locally fairly common. Occurs in Tambopata-Candamo Reserved Zone, in Peru, Beni Biosphere Reserve and Noel Kempff Mercado National Park, both in Bolivia, and Pantanal Mato-grossense and Tapajós National Parks, both in Brazil. Status of two small disjunct populations, one in E Colombia (Carimagua and Laguna Mozambique, in Meta) and the other in NE Peru (Moyobamba, in San Martín), not known.
Bibliography. Bates & Parker (1998), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Dubs (1992), Forrester (1993), Hennessey, Herzog & Sagot (2003), Hilty & Brown (1986), Kirwan *et al.* (2004), Meyer de Schauensee (1982), Oren & Parker (1997), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1977, 1982), Willis & Oniki (1990, 1991), Zimmer (1940a).

156. Hangnest Tody-tyrant

Hemitriccus nidipendulus

French: Todirostre de Wied **German**: Grünrücken-Todityrann **Spanish**: Titirijí de Wied

Taxonomy. *E[uscarthmus] nidipendulus* Wied, 1831, River Mucuri, Bahia, Brazil.
Formerly treated in the defunct genus *Idioptilon*. Two subspecies recognized.
Subspecies and Distribution.
H. n. nidipendulus (Wied, 1831) - Sergipe (Itabaiana Reserve) and Bahia (Bonfim), in E Brazil.
H. n. paulistus (Hellmayr, 1914) - CE & SE Brazil (S Minas Gerais and Espírito Santo S to Rio de Janeiro and São Paulo).



Descriptive notes. 9·5-10 cm; 7·2-8 g. Crown, face and upperparts are bright olive-green, lores somewhat more yellowish; wings and tail olive, distinct yellow edging on wing-coverts and flight-feathers; throat and underparts white, breast and, especially, flanks with faint greyish-olive streaks; iris creamy white; bill brown, base of lower mandible greyish flesh-coloured; legs light grey. Sexes alike. Race *paulistus* is slightly larger and has longer tail than nominate. Voice. Fast "weet-weet-weet" or "tic, prrew-prrew-prrew" and clear high "tiréé-téélili téélili téélili", a syncopated series unlike voice of any congeners, and reminiscent of *Todirostrum*.
Habitat. *Restinga*; humid evergreen forest, especially dense woodland, secondary forest, and *Pteridium aquilinum* thickets in foothills; from near sea-level to 900 m.
Food and Feeding. Insects. Forages alone, occasionally in pairs, in lower growth of forest, usually inside thickets and tangles; makes short upward strikes to glean prey from leaf undersides.
Breeding. Nest with eggs in early Oct. Nest domed, pyriform, with side entrance, constructed from dry stems, rootlets, leaves of *Spartina* grass and other plant material, lined with hair, suspended from twig c. 1·5 m above stream; one was 8 cm in maximum diameter, 13 cm long, with streamer 26 cm long of dangling dry leaves, entrance hole 3 cm across, protected by awning 4 cm long. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to common. Common in Patrimônio Natural do Caraça Special Reserve and in Mata dos Godoy State Park (Paraná). Also occurs in Itabaiana Reserve (Sergipe), Serra Paranapiacaba International Biosphere Reserve and Itatiaia National Park. Recent observations at Itabaiana represent the most NE records to date.
Bibliography. Bauer & Pacheco (2000), Cohn-Haft (1996), Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), Euler (1900), Ferreira de Vasconcelos & Melo-Júnior (2001), Forrester (1993), Ihering (1900), Meyer de Schauensee (1982), Pacheco & Whitney (1995), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Tobias *et al.* (1993), Traylor (1977).

157. Pearly-vented Tody-Tyrant

Hemitriccus margaritaceiventer

French: Todirostre à ventre perle **German**: Perlbauch-Todityrann **Spanish**: Titirijí Perlado

Taxonomy. *T[odirostrum] margaritaceiventer* d'Orbigny and Lafresnaye, 1837, Chiquitos, Santa Cruz, Bolivia.
Formerly treated in genera *Euscarthmornis* and *Idioptilon*, both now defunct. Previously considered conspecific with *H. inornatus*. Recently described isolated race *chiribiquetensis* demonstrates closer affinity to Andean forms than to nearby tepui populations. Race *septentrionalis* perhaps indistinguishable, may be better merged with *impiger*. Nine subspecies recognized.
Subspecies and Distribution.
H. m. impiger (P. L. Sclater & Salvin, 1868) - NC Colombia (Magdalena S to Santander) and N Venezuela (N & W Zulia E to Sucre and C Anzoátegui, including Margarita I).
H. m. septentrionalis (Chapman, 1914) - C Colombia (upper Magdalena Valley S from N Tolima).
H. m. chiribiquetensis Stiles, 1995 - Sierra de Chiribiquete (Caquetá), in S Colombia.
H. m. duidae (Chapman, 1929) - Cerro Duida (Amazonas), in S Venezuela.
H. m. breweri (Phelps, Jr, 1977) - SW Bolívar (Massif of Jaua), in S Venezuela.
H. m. auyantepui (Gilliard, 1941) - tepuis of SE Bolívar (SE Venezuela).
H. m. rufipes (Tschudi, 1844) - arid valleys of C & S Peru (S from Junín and Cuzco) S to NW Bolivia (La Paz, S Beni).
H. m. wuchereri (P. L. Sclater & Salvin, 1873) - NE Brazil (Maranhão, Ceará, Pernambuco, Bahia).
H. m. margaritaceiventer (d'Orbigny & Lafresnaye, 1837) - E & SE Bolivia, EC & S Brazil (Mato Grosso and Goiás S to W Minas Gerais and São Paulo), Paraguay and NE Argentina (S to Córdoba and Entre Ríos).

Descriptive notes. 10-10·5 cm; 7-10 g. A drab, greyish, long-billed pygmy-tyrant of dry country. Nominate race is plain, drab greyish-brown to brownish-olive above, crown somewhat more grey, lores and eyering whitish; wings dusky, buff-whitish to yellow wingbars and edges of remiges; tail dusky; throat and underparts white with indistinct greyish streaking; iris pale straw-coloured, "bloodshot" orange, or pale hazel; bill reddish-brown to blackish, lower mandible pinkish-brown to flesh-coloured; legs pink to pale greyish-flesh. Sexes alike. Race *impiger* has deep buff-brown crown and upper back; *septentrionalis* has greyer upperparts, blacker and more rounded bill; *chiribiquetensis* is most like previous, but upperparts greyer, crown darker, wingbars paler and more contrasting, streaks on throat much more pronounced and blacker, flanks more tinged with yellow; *duidae* has dark brown upperparts, buffy to pale orange-yellow belly, reddish bill; *auyantepui* has grey-white belly, upperparts medium brown with only slight olivaceous tinge; *breweri* rather dark, with pale ochraceous-buff belly; *rufipes* has top of head more olivaceous-tinged (especially posteriorly), yellower flanks and crissum; *wuchereri* has back much less greenish, throat more distinctly streaked. Voice. Most often a series of sharp staccato notes followed by brief to long, musical trill that may rise or, more often, fall in pitch, "tick-tick-tr'r'r'r'r'r'r'r", sometimes staccato notes given alone; also brief nasal trill or soft, mechanical, frog-like buzz; call notes, frequently given while foraging, are loud, sharp "tuk, tuk, quéek, quéek", or 2-4 "quéek" notes each higher-pitched than preceding one.
Habitat. Mainly shrubby, arid to semi-arid scrub, lower growth of taller deciduous woodland, and shrubby cattle pastures, less often dense riparian growth; also dense heath-like scrub on Gran Sabana (Venezuela) and *Bonnetia* scrub in Sierra de Chiribiquete (S Colombia). Sea-level to 2000 m, mostly below 1000 m.
Food and Feeding. Insects. Forages alone or, more frequently, in pairs at lower to middle heights in shrubs and low trees, sometimes within a few centimetres of ground, mainly at eye level; makes brief pauses and short upward strikes to glean insects from leaf undersides.
Breeding. Jan-Jun in Colombia, Oct-Dec in Peru, Bolivia and Argentina. Nest a hanging elongated purse, domed, with lateral entrance near bottom, small awning projecting above entrance, constructed from dry grass blades, fine plant fibres and varying amount of plant down, profusely lined with whitish to deep rusty-buff plant down, suspended 0·5-3 m above ground from drooping branch of tree, shrub or herbaceous plant. Clutch 2-3 eggs, most commonly 2, occasionally 1; no information on incubation period; nestling period 13-14 days.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common. Occurs in Beni Biosphere Reserve and Madidi and Noel Kempff Mercado National Parks, all in Bolivia, Caaguazú, San Rafael, San Luis and Ybycuí National Parks, all in Paraguay, and San Juan de Poriahú Private Reserve (in Iberá Provincial Reserve), in Argentina. In Brazil, occurs in Mata dos Godoy State Park (Paraná) and Brasília and Serra da Canastra National Parks, and reported also from Mata Estrela Private Reserve (Rio Grande do Norte). Range may extend farther S in E parts, as this species has been reported from Cerro Corá National Park, in Uruguay.
Bibliography. Bates & Parker (1998), Brooks *et al.* (1993), Canevari *et al.* (1991), Chapman (1914, 1931), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Davis (1993), Di Giacomo (2004), Dubs (1992), Fitzpatrick (1980c), Fjeldså & Maijer (1996), Friedmann (1927), Friedmann & Smith (1950), Gilliard (1941),, Hayes (1995), Hilty (2003), Hilty & Brown (1986), Ihering (1900), López (1997), Lowen *et al.* (1996), Mayr & Phelps (1967), Meyer de Schauensee & Phelps (1978), Miserendino (1998), Narosky & Salvador (1998), de la Peña (1987, 1988, 1996), Ridgely & Tudor (1994), Schmitt *et al.* (1997), Short (1975), Sick (1993, 1997), Stiles (1995), Stotz *et al.* (1996), Todd & Carriker (1922), Traylor (1977), Wetmore (1926, 1939), Willis & Oniki (1990), Zimmer (1940a).

158. Pelzeln's Tody-tyrant

Hemitriccus inornatus

French: Todirostre de Pelzeln **German**: Pelzelntodityrann **Spanish**: Titirijí de Pelzeln

Taxonomy. *Euscarthmus inornatus* Pelzeln, 1868, River Içana, right bank of upper Rio Negro, north-west Brazil.
Thought to form a superspecies with *H. minimus* on basis of complementary distributions and similarities in habitat and voice. Formerly considered a race of *H. margaritaceiventer*. Monotypic.
Distribution. Very locally on R Negro and tributaries, in NW Brazil; probably also in adjacent Venezuela and Colombia.

Descriptive notes. 9 cm; 7·7-9 g. Crown and upperparts are brownish-olive, lores and narrow eyering whitish; wings and tail dusky olive-brown, whitish edgings of flight-feathers, whitish tips of wing-coverts (narrow wingbars); throat and underparts white with indistinct greyish streaking; iris whitish to pale grey; bill grey; legs grey. Differs from similar *H. margaritaceiventer impiger* by slightly smaller size, tone of upperparts, whiter (less yellow) wingbars. Sexes alike. Voice. Stuttered trill, short set of rapidly delivered low, insect-like notes, "tid-dip, tid, te'de" with scraping quality; very similar to *H. minimus*.
Habitat. Inhabits tall to stunted, patchily distributed white-sand woodland (known locally as *campinarana*).
Food and Feeding. Few data. Forages in low canopy and subcanopy, presumably making upward strikes similar to those of other members of genus.
Breeding. No information.
Movements. Presumably resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Orinoco-Negro White-sand Forests EBA. Locally common. Until recently, known only from a single 19th-century specimen (Jun 1831) from R Içana, a right-bank tributary of upper R Negro in NW Brazil. Rediscovered in Oct 1992, on E bank of lower R Negro (45 km N of Manaus), and found there again in Feb 1993, thus extending the species' range by c. 1000 km; has subsequently been discovered also on R Apuaú and R Cuieras, which are right-bank tributaries of R Negro. Much of its habitat remains in relatively pristine condition owing to low human population density and inaccessibility, but cattle grazing, extraction of white sands, gold-mining and diamond-mining, and frequent fires pose serious local threats. Possible presence of this species in adjacent parts of Venezuela and Colombia should be investigated.
Bibliography. Cohn-Haft (2000), Cory & Hellmayr (1927), Forrester (1993), Hilty (2003), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Whittaker (1994).

159. Zimmer's Tody-tyrant

Hemitriccus minimus

French: Todirostre de Zimmer **German**: Zwergtodityrann **Spanish**: Titirijí de Zimmer

Taxonomy. *Snethlagea minima* Todd, 1925, Itaituba, River Tapajós, Brazil.
Thought to form a superspecies with *H. inornatus* on basis of complementary distributions and similarities in habitat and voice. Was for long regarded as a weakly defined race of *H. minor*; recent study of original series of specimens, however, revealed existence of two separate species, also that described taxon *H. aenigma* is identical to holotype of present species, with which therefore synonymized. Monotypic.
Distribution. Scattered Amazonian localities in SE Ecuador (Kapawi), NE Peru (near Iquitos), Brazil (NW Acre and Amazonas E to Manaus and S Pará), and NE Bolivia (W of Versalles, in Beni;

Serranía de Huanchaca, in Santa Cruz); suspected to occur widely across Amazonia where appropriate habitat exists.

Descriptive notes. 10 cm; 6-8 g. Has upperparts brownish-olive, darker brown crown streaked darker dusky; lores and indistinct eyering buffy, auriculars brown; wings dusky, two distinct yellowish wingbars, yellow edges of inner flight-feathers and less distinct yellow on outer remiges (two-toned effect); throat white with distinct dusky streaking, lower throat, breast and sides yellowish olive-buff with indistinct dusky streaking, centre of belly pale yellow; iris white to pale straw-coloured; bill black, lighter at base; legs grey to pinkish-grey. Sexes alike. Voice. Soft, twittering, tinkling, ventriloquial trills that are rather loud (but difficult to locate), similar to calls of *H. inornatus* but lacking two-part stuttering rhythm. Also possible dawn song, 1-4 evenly spaced single notes at both beginning and end of a tight burst of c. 3 notes of greater frequency range and higher peak frequency, the whole lasting c. 1·5 seconds.

Habitat. Stunted forest and vine tangles in black-water regions, on nutrient-poor sandy soil, this vegetation formation often called *campinarana*; recorded up to 450 m.

Food and Feeding. Insects. Forages in pairs in crowns of stunted forest trees (9-12 m), and at similar heights among viny tangles in foliage of taller forest; makes short upward strikes typical of genus.

Breeding. No information.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon and very local. Occurs in Rio Cristalino Forest Reserve and Jaú and Tapajós National Parks, in Brazil; Kapawi Ecological Reserve, in Ecuador; and Noel Kempff Mercado National Park, in Bolivia. Very poorly known.

Bibliography. Álvarez & Whitney (2003), Anderson (1981), Bates & Parker (1998), Bates, Parker *et al.* (1992), Bates, Stotz & Schulenberg (1998), Borges *et al.* (2000), Cohn-Haft (2000), Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), Forrester (1993), Hennessey, Herzog & Sagot (2003), Meyer de Schauensee (1982), Oren & Parker (1997), Parker *et al.* (1991), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz (1992), Stotz *et al.* (1996), Zimmer, J.T. (1940a), Zimmer, K.J. *et al.* (1997).

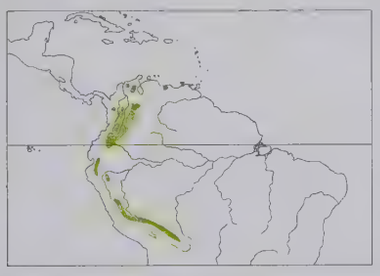
160. **Black-throated Tody-tyrant**



Hemitriccus granadensis

French: Todirostre à gorge noire **German**: Schwarzkehl-Todityrann **Spanish**: Titirijí Gorginegro

Taxonomy. *Todirostrum granadense* Hartlaub, 1843, "Bogotá" = Santa Elena, Antioquia, Colombia. Formerly treated in genus *Euscarthmornis* and later in *Idioptilon*, both of which are now defunct. Possibly a member of the superspecies formed by *H. mirandae*, *H. cinnamomeipectus* and *H. kaempferi*. Vocal and plumage differences across its range suggest that more than one species may be involved. Race *andinus* doubtfully distinct from *intensus*. Seven subspecies currently recognized.

Subspecies and Distribution.

H. g. lehmani (Meyer de Schauensee, 1945) - Sierra Nevada de Santa Marta, in N Colombia.
H. g. intensus (Phelps, Sr & Phelps, Jr, 1952) - NW Venezuela (Sierra de Perijá, SW Táchira).
H. g. federalis (Phelps, Sr & Phelps, Jr, 1950) - N Venezuela (Distrito Federal).
H. g. granadensis (Hartlaub, 1843) - Colombia (W & C Andes) and N Ecuador (W slope in Carchi, E slope S to W Napo).
H. g. andinus (Todd, 1952) - E Andes in W Venezuela (Páramo de Tamá, in Táchira) and Colombia (Norte de Santander and Santander).
H. g. pyrrhops (Cabanis, 1874) - SE Ecuador (E Loja) and Andes of Peru (Amazonas S to Cuzco).
H. g. caesius (Carriker, 1932) - SE Peru (Puno) and W & WC Bolivia (La Paz, Cochabamba).

Descriptive notes. 10·5 cm; 6·5-8·5 g. Nominate race has crown and upperparts dark olive, whitish loral and ocular area forming broad eyering and "spectacles"; wings dark olive, indistinct yellow edging on wing-coverts (but no discrete wingbars), bend of wing bright yellow; tail dark dusky olive; upper throat and lower cheek sooty black, lower throat whitish, laterally more grey; diffuse breastband greyish, fading to white below, tinged yellow on lower flanks and crissum; iris chestnut to pale orange, varying significantly among individuals; bill black; legs grey to pinkish-grey. Sexes alike. Juvenile has dark brown iris. Race *lehmani* has brighter, more yellowish-green, upperparts, buff lores and ocular area, brownish-black throat, brownish cast to breast, iris sometimes pale to whitish; *intensus* resembles previous, but has blacker throat with less brownish tinge, pure grey breast; *federalis* has whiter breast; *andinus* has lores buffy, breast less solidly grey; *pyrrhops* has ocular area deep cinnamon; *caesius* has eyering pale ashy grey or greyish-white, smaller loral patch and less black on central throat. Voice. Call (nominate race) a gravelly "dut't't, dut't't", a nasal "tip-buuuuu" and sharp "pik, peet, peet"; *pyrrhops* a fast, soft "whididik" and, when excited, a sharp, nasal, nagging "whip-wheép-wheép-wheép-wheép". Dawn song "kee kee kee krrrrrrrt", ending in hard, sharp trill. While patrolling gives short trill, "krrrt"; alarm call repeated "keep keep", like that of a *Synallaxis* spinetail like. Wing-whirring in flight.

Habitat. Humid, mossy montane forest, stunted upper cloudforest, shrubby second growth and shrubby cloudforest borders; 1800-3300 m, mostly 2000-3000 m.

Food and Feeding. Insects. Forages singly or in pairs, occasionally following mixed-species flocks, in lower and middle storey. Perches in relatively open surroundings within vegetation, making short, explosive upward strikes to glean prey from undersides of leaves.

Breeding. Birds with enlarged gonads in Mar-Jul in Colombia and Dec in Peru. Clutch 2 eggs. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Occurs in Tambito Nature Reserve, in Colombia, Podocarpus National Park, in Ecuador, and Río Abiseo National Park and Machu Picchu Historical Sanctuary, in Peru. Race *andinus* very poorly known, perhaps only definitely known from type locality in SE Peru (Puno), though possibly also occurs in Bolivia (La Paz).

Bibliography. Chapman (1917c), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Fjeldså & Krabbe (1990), Hennessey, Herzog & Sagot (2003), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1945, 1982), Meyer de Schauensee & Phelps (1978), Miller (1963), Parker *et al.* (1980), Phelps & Phelps (1950), Poulsen (1994), Remsen (1985), Remsen & Traylor (1983), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Todd (1952), Traylor (1977), Walker (2001), Zimmer (1940a).

161. **Buff-breasted Tody-tyrant**

Hemitriccus mirandae

French: Todirostre de Miranda **German**: Ockerbauch-Todityrann **Spanish**: Titirijí de Miranda

Taxonomy. *Todirostrum mirandae* E. Snethlage, 1925, São Paulo, Serra da Ibiapaba, north Ceará, Brazil.

Formerly treated in now defunct genus *Idioptilon*. Forms a superspecies with *H. cinnamomeipectus* and *H. kaempferi*, perhaps also including *H. granadensis* and *H. furcatus*. Monotypic.

Distribution. NE Brazil, on isolated ridges of N Ceará, Paraíba, Pernambuco, Alagoas and S Bahia.

Descriptive notes. 10 cm. Crown and upperparts are darkish olive, wings and tail dusky olive, broad creamy edge of innermost secondaries; lores, ocular area, cheek, throat and breast uniform pale creamy buff, belly more whitish, grading into pale yellow on crissum; iris orange; bill grey, lower mandible paler; legs grey to flesh-coloured. Sexes alike. Voice. Slow, slightly ascending (or, sometimes, descending) set of 6-7 notes, "kt-kit-kit-kiit-kiit-kiiit-kit", repeated in series; reminiscent of *H. orbitatus*. Sometimes audible wing-whirring in flight.

Habitat. Semi-humid highland forest and shrubby second-growth forest; found exclusively along slopes of isolated forested ridges at 600-1000 m.

Food and Feeding. Insects. Most often solitary. Forages in understorey and mid-levels of forest, especially in thick vine tangles, usually at 2-5 m; makes short upward strikes to glean prey from leaf undersides.

Breeding. No published information. Nest reported as pendent.

Movements. Resident.

Status and Conservation. VULNERABLE. Restricted-range species: present in Atlantic Slope of Alagoas and Pernambuco EBA. Uncommon and very local. Global population of a few thousand individuals; severely fragmented range of c. 1800 km², and habitat subjected to ongoing and rapid decline owing to massive deforestation. In 1991, was found at unprotected Fazenda Gameleira (Tianguá), on the Serra da Ibiapaba, and at Guaramirangá, in the 32,690-ha Serra do Baturité State Environmental Protection Area, both in Ceará; effectiveness of protection in latter area unclear, but local hotels protect some habitat. Found also at Areia, in Paraíba, and at several sites in Pernambuco state (may occur in the 350-ha Tapacurá Ecological Station). Recorded regularly in the 4500-ha Pedra Talhada Biological Reserve, which protects one of last remaining upland Atlantic Forest tracts in Alagoas; significant areas in Pedra Talhada are being reforested with native trees, and protection is enforced by guards and welcomed by the local community. Only 1% of original forest remains in Serra do Baturité, largely as a result of clearance for "sun" coffee since early 1970s, and the situation is similar or worse in Serra da Ibiapaba; remaining habitat threatened by fires and the construction of holiday homes. Only 2% of original cover is left in Alagoas and Pernambuco and 6% in Paraíba, with most forest replaced by sugar-cane plantations at low elevations and degraded by selective logging, firewood removal and small-scale cultivation at higher elevations. Although the species has been observed in secondary growth, it is confined to the best forest in Pedra Talhada. Only the protection of intact forest can secure the long-term survival of this tyrannid.

Bibliography. Bencke *et al.* (2001), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1927), Cracraft (1985), Fitzpatrick & O'Neill (1979), Forrester (1993), Meyer de Schauensee (1982), Parker *et al.* (1996), Ridgely & Tudor (1994), Sick (1993, 1997), Silveira *et al.* (2003), Stattersfield & Capper (2000), Stotz *et al.* (1996), Teixeira *et al.* (1993), Traylor (1977), Wege & Long (1995).

162. **Cinnamon-breasted Tody-tyrant**

Hemitriccus cinnamomeipectus

French: Todirostre du Pérou **German**: Zimtbrust-Todityrann **Spanish**: Titirijí Pechicanelo
Other common names: Peruvian Tody-tyrant

Taxonomy. *Hemitriccus cinnamomeipectus* Fitzpatrick and O'Neill, 1979, Cordillera del Cóndor, above San José de Lourdes, Cajamarca, Peru.

Forms a superspecies with *H. mirandae* and *H. kaempferi*, perhaps also including *H. granadensis* and *H. furcatus*. Monotypic.

Distribution. SE Ecuador (near Chinapinza, in Zamora-Chinchipe) and N Peru (Cordillera del Cóndor, in Cajamarca; Cordillera de Colán, in Amazonas; Abra Patricia, in San Martín).

Descriptive notes. 10 cm; 6·5-8·5 g. Plumage is dark olive above, crown slightly browner and separated from mantle by a buff-orange nuchal collar; lores, ocular area, cheek, throat and breast bright cinnamon, darkest around eye, contrasting sharply with darker crown; wings and tail dusky, distinct broad pale yellowish edging on innermost secondaries; belly uniform pale yellow, well demarcated from cinnamon of breast; iris light reddish-brown; bill greyish, lower mandible pale flesh-coloured, sometimes tipped brown; legs greyish to pinkish-grey. Sexes alike. Juvenile has upperparts washed brownish with a few emerging olive feathers, throat and breast pale sandy, belly whitish to pale yellow, bill all black, legs darker. Voice. Fast harsh rattle, "d-d-d-rt"; also described as single descending "prrrrrrr".

Habitat. Thick, stunted, mossy cloudforest; also found in stands of *Chusquea* bamboo. Apparently limited to isolated ridges, at 1700-2200 m.

Food and Feeding. Insects. Forages in middle and lower storeys of wet forest, mostly 1·5-2 m above ground; makes short upward sally-strikes to vegetation to glean prey, usually returning to different perch. Sometimes follows mixed-species understorey flocks.

Breeding. Birds near end of breeding season (juvenile present, only some adults with active gonads, others moulting) in late Jun to late Aug in N Peru; singing male vigorously responding to song playback in mid-Sept in Ecuador. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Andean Ridge-top Forests EBA. Rare to uncommon; red-listed, as "Vulnerable", in Ecuador. Recorded from about five remote and isolated mountain ranges. In Ecuador, was found in the Cordillera del Cóndor in 1990 and in the Cutucú Mts; possibly threatened by heavy gold-mining activity in the region. In Peru, recorded in Cordillera del Cóndor in 1976 and Cordillera de Colán in 1978, but not in 1994, when almost all forest had been cleared for timber, pasture and cash crops (particularly marijuana and coffee); at the pass around Abra Patricia (in Amazonas and San Martín), was fairly common in 1976 and 1989 in cloudforest and elfin forest that were relatively inaccessible and untouched, and fairly common in 1999 in bamboo stands at slightly lower elevation; also recorded near La Peca Nueva in 1978. Given its very small range and continuing habitat degradation, the species may merit the conservation status of Vulnerable.

Rusty-fronted Tody-flycatcher (*Poecilotriccus latirostris*).

Bibliography. Begazo *et al.* (2001), Clements & Shany (2001), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Davies *et al.* (1994, 1997), Fitzpatrick & O'Neill (1979), Hornbuckle (1999), Krabbe & Sornoza (1994), Pacheco (2002c), Parker *et al.* (1996), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stotz *et al.* (1996), Wege & Long (1995).

163. **Kaempfer's Tody-tyrant**

Hemitriccus kaempferi

French: Todirostre de Kaempfer **German**: Ockerbrust-Todityrann **Spanish**: Titirijí de Kaempfer

Taxonomy. *Idioptilon mirandae kaempferi* J. T. Zimmer, 1953, Salto do Piraí, 450 feet [c. 140 m], Santa Catarina, Brazil.
Formerly treated in the now defunct genus *Idioptilon* and originally regarded as a race of *H. mirandae*. Forms a superspecies with latter and *H. kaempferi*, perhaps also including *H. granadensis* and *H. furcatus*. Curved outer rectrices and buffy head coloration suggest a relationship to last-mentioned. Monotypic.
Distribution. SE Paraná and NE Santa Catarina, in SE Brazil.

Descriptive notes. 10 cm. Similar to geographically remote *H. cinnamomeipectus*. Has crown buffy olive, lores, ocular area and cheek buffy; upperparts dark olive; wings dark olive, buffish-olive wingbars, distinct broad pale yellow edges on outer web of innermost secondaries; tail dusky olive, pale-tipped outer rectrices slightly elongated and curved outwards; throat and breast dull ochraceous buff, washed greenish-olive, belly uniform pale yellow and well demarcated from ochraceous of breast; iris brown to warm fawn-brown; bill grey, lower mandible lighter; legs dark grey. Sexes similar, female with outer rectrices perhaps less modified. Voice. A short series of high-pitched, nasal, raspy notes, "kuít-kuít" or "kwit-kwit", sometimes "kwit kwit-kwit kwit-kwit kwit-kwit", similar to voice of *H. orbitatus*. Sometimes wing-whirring in flight.
Habitat. Lowland tropical evergreen forest and shrubby second growth, favouring low, shaded growth with *Cecropia* and heliconias among thick ground flora, often in close proximity to rivers; sea-level to 150 m.
Food and Feeding. Insects; lepidopteran caterpillar observed to be taken. Forages alone or in pairs in dense vegetation, 0·5-3 m above ground; long pauses separated by short upward strikes or hover-gleans to take insects from underside of leaves.
Breeding. No information.
Movements. Resident.
Status and Conservation. ENDANGERED. Restricted-range species: present in Atlantic Forest Lowlands EBA. Apparently rare, and known from only three localities. Global population perhaps a few hundreds to a few thousands, and severely fragmented as a result of habitat loss due to deforestation, agricultural conversion, urbanization and associated road-building. First discovered in 1929, but not formally named until much later. Rediscovered very near type locality, at Salto do Piraí (NW of Vila Nova), in 1991, and several records since; 4 km² of intact forest adjacent to the site are now protected in the Bracinho Ecological Station, but the species has not been recorded within the reserve. A specimen was collected at Brusque in 1950; no subsequent records from the site, although suitable habitat remains. In 1998 and 2000, the species was also found in the 15-km² Patrimônio Natural de Volta Velha Special Reserve, near Itapoá, which protects one of the last remnants of mature primary lowland forest in Santa Catarina. Recently found at a fourth locality, called "APA Guaratuba", in SE Paraná. Less than 20% of original Atlantic Forest is intact, and lowland forest in vicinity of all sites continuing to be cleared. Both reserves should be expanded to include the type locality and adjacent suitable habitats. Protected by Brazilian law.
Bibliography. Anon. (2003e), Buzzetti *et al.* (2003), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fitzpatrick (1976), Fitzpatrick & O'Neill (1979), Forrester (1993), Mazar Barnett *et al.* (2000), Meyer de Schauensee (1982), Mickleburgh & Fisher (2003), Naumburg (1939), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Teixeira *et al.* (1991), Wege & Long (1995).

164. **Buff-throated Tody-tyrant**

Hemitriccus rufigularis

French: Todirostre à gorge fauve **German**: Graukappen-Todityrann **Spanish**: Titirijí Gorgirrufo

Taxonomy. *Euscarthmus rufigularis* Cabanis, 1873, Monterico, Peru.
Formerly treated in genus *Euscarthmornis* and later in *Idioptilon*, both now defunct. Possibly allied to other brown-headed congeners, i.e. *H. granadensis*, *H. mirandae*, *H. cinnamomeipectus*, *H. kaempferi* and *H. furcatus*. Monotypic.
Distribution. Disjunctly along foothill ridges of E Andes in Ecuador (W Napo, Morona-Santiago, Zamora-Chinchipe), Peru (Loreto, San Martín, and from Huánuco S to N Puno) and N Bolivia (La Paz, extreme SW Beni, W Santa Cruz).

Descriptive notes. 12 cm; 7·8-9·5 g. Largest member of genus. Plumage is rather light olive above, crown greyer, supraloral spot, ocular area and cheek pale dull buff; wings and tail plain olive, indistinct paler olive edges of remiges and wing-coverts; throat buffy whitish, breast dull buff, both faintly streaked grey, belly whitish (Bolivian birds tend to be duller and more extensively streaked below); iris white to straw-yellow; bill grey, lower mandible greyish-flesh; legs greyish-pink or purple. Sexes alike. Voice. Vocalizes persistently throughout day, a nagging nasal "kik-keek-keek keek-kéék" or "kw-díp, kw-díp, kw-díp, kwe-deep" in series, usually 4-10 notes, later notes somewhat higher and louder; also simpler, less insistent, 2-note version of similar quality; voice resembles that of *H. granadensis*.
Habitat. Humid foothill forest on isolated low massifs; 800-1500 m.
Food and Feeding. Insects. Forages singly or in pairs; occasionally joins mixed-species flocks. Perches 2-8 m above ground, well below canopy, in continuous forest; makes short upward strikes to glean prey from undersides of leaves. Generally resides in small, persistent territory only 100-150 m in diameter.
Breeding. Oct-Dec in SE Peru. Nest an elongated structure woven from grass blades and weak twigs; rounded side entrance covered by short, downward-pointing awning; long, ragged bottom hanging below ball-shaped inner pocket; suspended 1 m above ground from outermost end of understorey twig, with hanging material almost reaching ground. Clutch 2 eggs; no information on incubation and fledging periods.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Rare to uncommon and very local. Recorded at only four sites in Ecuador, on S slope of Volcán Sumaco and along Loreto road, in Napo, in Codillera de Cutucú, in Morona-Santiago, and in Cordillera del Cóndor, in Zamora-Chinchipe; at a few scattered localities in Peru and W Bolivia. In Peru, much of this species' habitat is relatively intact above 900 m, but widespread destruction of foothill forests has taken place elsewhere in its range, where effects of extensive agricultural conversion and logging have been amplified by road-building and human colonization. Most of its range, however, is in remote areas.
Bibliography. Carrión & Sibley (1992), Clements & Shany (2001), Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), Davis (1986), Fitzpatrick (1976), Fitzpatrick & O'Neill (1979), Hennessey, Herzog & Sagot (2003), Hornbuckle (1999), Krabbe (1992), Meyer de Schauensee (1982), Parker *et al.* (1996), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg & Servat (2001), Schulenberg *et al.* (2001), Stattersfield & Capper (2000), Stotz *et al.* (1996), Traylor (1977), Zimmer (1940a).

165. **Fork-tailed Pygmy-tyrant**

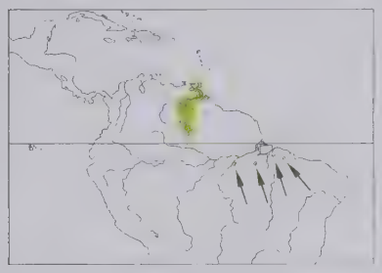
Hemitriccus furcatus

French: Todirostre à queue fourchue **Spanish**: Titirijí Tijereta
German: Gabelschwanz-Todityrann
Other common names: Fork-tailed Tody-tyrant

Taxonomy. *T[odirostrum] furcatum* Lafresnaye, 1846, Rio de Janeiro, Brazil.
Formerly placed in a monotypic genus, *Ceratotriccus*, on basis of distinctive elongated and forked tail. Possibly a member of the superspecies formed by *H. mirandae*, *H. cinnamomeipectus* and *H. kaempferi*, possibly also including *H. granadensis*. Monotypic.
Distribution. CE & SE Brazil, in Bahia, S Minas Gerais, Rio de Janeiro and E São Paulo.

Descriptive notes. 11 cm. Has bright cinnamon-brown on forehead, becoming brownish-olive on nape and crown, face cocoa-brown to cinnamon, loral spot and eyering pale cinnamon-buff; upperparts bright olive; wings bright olive, distinct bright cinnamon edging on inner flight-feathers, broad creamy edge on outer web of innermost secondaries; tail distinctive, very long, outer rectrices longest and slightly curved inwards, mainly olive, with prominent white tips and black subterminal band; throat cocoa-brown, bordered below by clear white band or spot on centre of chest; breast and flanks pale greyish, slightly flammulated, belly more whitish; iris orange-brown; bill grey, lower mandible paler, pinkish to yellowish; legs grey to flesh-coloured. Sexes similar, tail slightly more prominently forked on male. Voice. High-pitched, fast, staccato "chídididik" or "kikky-tutu", in a series usually at intervals of 3-8 seconds.
Habitat. Humid forest and second growth along borders, especially in large-leaved bamboo thickets and viny tangles; to 1200 m. Original habitat may have been thickets growing along edges of natural landslides.
Food and Feeding. Insects. Usually solitary, only rarely joining mixed-species flocks. Makes short upward sally-strikes to glean insect prey, often from underside of bamboo leaves.
Breeding. Recently fledged juveniles in Nov in Bahia. No other information.
Movements. Resident.
Status and Conservation. ENDANGERED. Restricted-range species: present in Atlantic Forest Lowlands EBA. Generally judged to be rare to locally uncommon, though perhaps often overlooked. Estimated global population fewer than 10,000 individuals in a range of c. 3200 km². Recent records from only six localities, of which five in protected areas, i.e. Itatiaia National Park, Ubatuba Experimental Station, Serra do Mar State Park, Boracéia Biological Station, and Desengano State Park; last-mentioned is still threatened by deforestation. Discovered near Boa Nova, in Bahia, in 1993, thus extending its known range by c. 1000 km N. In the privately protected Fazenda Angelina, near Ubatuba, 1 pair/100 m, making it the commonest bird species in its particular habitat. Population severely fragmented by habitat loss due to deforestation, agricultural conversion, urbanization and associated road-building, leaving less than 20% of original forest cover intact. Smallholder farms are rapidly encroaching on remaining forests around Boa Nova. Protected by Brazilian law.
Bibliography. Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1927), Cracraft (1985), Fitzpatrick (1976), Forrester (1993), Gonzaga *et al.* (1995), Meyer de Schauensee (1982), Pacheco & Whitney (1995), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Tobias *et al.* (1993), Traylor (1977), Wege & Long (1995).

Genus *TAENIOTRICCUS*



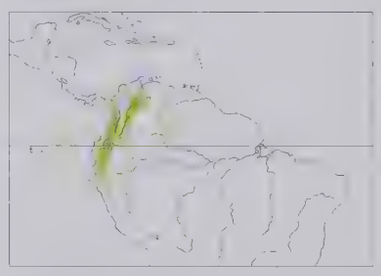
Berlepsch & Hartert, 1902

166. **Black-chested Tyrant**

Taeniotriccus andrei

French: Todirostre d'André **Spanish**: Mosquero Pechinegro
German: Schwarzschopf-Todityrann

Taxonomy. *Taeniotriccus andrei* Berlepsch and Hartert, 1902, La Prisión, River Caura, Bolívar, Venezuela.
Genus subsumed into *Poecilotriccus* by some authors, a move supported by additional research on internal morphology. Other authors have argued for retention of this monotypic genus on the basis of several distinctive morphological features, notably the crest, bill shape, wing and facial patterns, unusual comb-like feathers above the eyes, and the ruff-like feathering of the head and nape; this treatment is also supported by recent information on vocalizations. Validity of poorly known race *klagesi* has been questioned, but apparent large geographical separation from nominate, along with possible plumage distinctions, argue for maintaining it at any rate for the present. Two subspecies currently recognized.
Subspecies and Distribution.
T. a. andrei Berlepsch & Hartert, 1902 - NE & EC Venezuela in Monagas, Delta Amacuro and N Bolívar (mostly lower and middle R Caura and R Paragua), and extreme N Brazil (NE Amazonas, N Roraima).
T. a. klagesi Todd, 1925 - EC Brazil S of Amazon (S Pará, N Maranhão).



Descriptive notes. 12 cm; 8-9·6 g. Distinctive, with lax, ruff-like crest, modified bristly feathers projecting from above and in front of eyes. Male has forehead, chin, throat, side of face and nape rufous-chestnut; much of crown occupied by elongate black crest overlying and concealing rufous of nape (when crest held flat); upperparts and tail deep black; wings largely black, prominent pale yellow bases of outer webs of all remiges except outermost primaries and crossing to inner webs of tertials (especially extensively on longest), tertials furthermore with outer webs entirely pale yellow; breast covered by broad black band continuous with black of upperparts, belly abruptly pale grey, lightening posteriorly, and with greenish-yellow tinge on flanks and undertail-coverts; iris dark brown or reddish-brown; bill black, sometimes contrastingly pinkish basal portion of lower mandible; legs pale grey. Female differs from male in having black crest shorter, back brownish-olive, rufous of face and throat often duller, breast medal-bronze to olive-grey, belly more broadly whitish medially, flanks and undertail-coverts more strongly tinged olive, also tail dull blackish, outer margins of remiges noticeably brownish. Race *klagesi*, described on basis of a single female, is said to differ from nominate in more olive-grey breast and more whitish abdomen; field observations suggest that it also has more olive back and more contrastingly grey nape. Voice. Most commonly heard vocalization (particularly among spontaneously calling individuals) a reedy single-note "chewp" or "chert", repeated at regular intervals of c. 3-4 seconds for up to 5 minutes or more. Much less frequently heard is a pair of couplets, components of which are not distinctly disyllabic but sound more diphthongal, with first part of couplet sharper, second part clearer but with some of the reedy, wood-on-wood quality of the single-note call, could be transcribed as "k'dink k'dink"; these paired couplets rarely delivered consecutively in sequences but, rather, inserted into series of "chewp" calls, and given more frequently by individuals responding to tape playback (only occasionally by spontaneously vocalizing birds). Functional differences between the two types of vocalizations (i.e. song versus call) not obvious. Female occasionally gives single-note calls similar to those of male, but not heard to deliver the paired couplet.
Habitat. Understorey of humid tropical lowland evergreen forest and forest edge, particularly in seasonally flooded forest (*várzea*); present up to 350 m. Most Venezuelan records from swampy tidal forest dominated by mangrove and palms in Orinoco Delta; in Monagas, also in bamboo within *várzea* (where bamboo admixed with small, regenerating banana plantation). In Brazil, found in bamboo-dominated understorey in *terra firme* forest along R Xingu, and in rank understorey of *Cecropia*-dominated second growth near rivers; in Carajás region of Pará, occupies dense viny thickets and tangles in partially flooded *várzea* immediately adjacent to riverbanks, also "vine forest" many kilometres from major rivers and where forest somewhat swampy, with canopy broken and fairly low, with abundance of *Cecropia*, palms and small leguminous trees and shrubs, and with trees of family Lecythidaceae (mostly Brazil nut, *Bertholletia excelsa*) as the primary scattered emergents. In last-mentioned habitat, much of forest was in seemingly arrested state of perpetual second growth, perhaps partially maintained by lush blanket of vines overtopping most of the smaller trees.
Food and Feeding. Probably feeds on variety of insects and other small arthropods; only items identified in field observations were small orthopterans. All foraging data from Carajás region of Pará (Brazil). Forages singly or in pairs, separately from mixed-species flocks, 1-12 m (mostly 1-5 m) above ground, mostly in settings in which light penetration allows dense foliage and vine tangles to form fairly solid canopy that shades more open perches below. Usually perches on bare horizontal or diagonal branches or vines; typical posture three-quarters upright, with back slightly hunched and tail somewhat drooped; remains on single perch for period of 5 seconds to more than 1 minute, during which actively scans for prey, while often flicking both wings simultaneously, sometimes accompanied by shallow up-and-down twitch of tail. Most changes of perch accompanied by audible wing-whirr. Attack manoeuvres usually consist of diagonal and horizontal sally-gleans of 30 cm to 2·5 m, mostly to bare branches, stems or vines, but also to live foliage; sallies directed both upwards and downwards; in most instances the bird follows through to a new perch, but sometimes it will make looping sallies before returning to its original perch; most prey captures are accompanied by audible bill-snap. Smaller prey tends to be consumed immediately, whereas larger items are often bashed against branches prior to swallowing; one female was observed to hold a medium-sized arthropod in her bill and rub it vigorously through various feather groups before consuming it.
Breeding. Nothing known.
Movements. Presumed resident throughout range.
Status and Conservation. Not globally threatened. Poorly known; generally considered rare and patchily distributed throughout range, although it appears to be at least locally not uncommon, for instance in lowlands of Floresta Nacional de Carajás, in Pará (Brazil). Perhaps better treated as Data-deficient. It is likely that hitherto unidentified specific micro-habitat requirements restrict this species' presence to habitats that are themselves patchily distributed through EC Venezuela and Brazil. Most areas in which it has been found are under little current threat of development, and it seems to tolerate some second-growth and edge habitats. It occurs in e.g. Misión Araguaimujo (Delta Amacuro) and Caño Colorado (Monagas), both in Venezuela, and Tapajós National Park, Brazil.
Bibliography. Aleixo *et al.* (2000), Berlepsch & Hartert (1902), Cory & Hellmayr (1927), Donahue & Pierson (1982), Fitzpatrick (1976), Graves & Zusi (1990), Hilty (2003), Kirwan & Sharpe (1999), Lanyon (1988a), Meyer de Schauensee (1982), Novaes (1978b), Oren & Parker (1997), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Todd (1925), Traylor (1977), Zimmer & Whittaker (2004).

Genus *POECILOTRICCUS* Berlepsch, 1884

167. **Rufous-crowned Tody-tyrant**
Poecilotriccus ruficeps

French: Todirostre bariolé **German**: Rostkappen-Todityrann **Spanish**: Titirijí Capirrufo
Other common names: Rufous-crowned Tody-flycatcher

Taxonomy. *Tod[iramphus] ruficeps* Kaup, 1852, "? Mexico"; error, type presumably a "Bogotá" (Colombia) skin.
Formerly placed in genus *Todirostrum*. Forms a superspecies with *P. luluae*. Races appear to form two groups on plumage type, namely "bridled group" (*melanomystax*, *peruvianus*) and "plain-headed group" (nominate, *rufigenis*); two specimens from Boyacá may be hybrids (*melanomystax* x nominate), but otherwise lack of intergradation between the two groups, combined with notable plumage differences, suggests the groups may represent two separate species, although vocalizations similar; reproductive isolation of the two groups would help to explain curious leapfrog distribution of races; further study required, especially in areas of contact between subspecies groups, in particular S Ecuador and Boyacá; *P. luluae* probably represents a further, more definitively separated offshoot of the same lineage. Four subspecies currently recognized.
Subspecies and Distribution.
P. r. melanomystax Hellmayr, 1927 - Andes in W Venezuela (N Mérida, E Trujillo) and C Colombia (Antioquia S to Cauca and head of Magdalena Valley, also Boyacá).
P. r. ruficeps (Kaup, 1852) - extreme SW Venezuela (S Táchira), and NE (Norte de Santander) & SW Colombia S to SC Ecuador.
P. r. rufigenis (P. L. Sclater & Salvin, 1877) - SW Colombia (Nariño) and NW Ecuador.
P. r. peruvianus Chapman, 1924 - S Ecuador (Loja, Zamora-Chinchipe) and N Peru (Piura, Cajamarca).

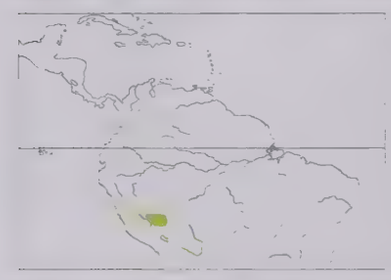
Descriptive notes. 9-10·2 cm; 6·6 g. Nominate race has distinctive bright rufous crown and grey nape separated by black line which connects with thin black malar stripe; white to buffy supraloral area and and cheek separated by thin black eyestripe; olive upperparts; black wings, two fairly narrow yellow wingbars, yellowish-white edges of remiges and tertials; olive-brown tail; throat and upper breast buffy whitish, diffuse dusky breastband, remaining underparts bright yellow; iris dark brown; bill black; legs grey. Sexes alike. Juvenile has paler throat than adult. Race *rufigenis* has malar streak indistinct or lacking; *peruvianus* has more pronounced black facial markings; *melanomystax* has whitish cheeks. Voice. Call low-pitched flat "chak", "tttrew", "patreer-pít" or "pip-prrrrrr", last note sometimes omitted; "tick-trrrrt" during foraging. Song usually a series of sputters, e.g. "pa-treer-pit-pit-pit", that of *melanomystax* described as gravelly "stick-di-dik".
Habitat. Thickets, bamboo, shrubs and small saplings at forest edges, in second growth, hedgerows, overgrown pastures and clearings; not found inside closed forest. Usually 1600-2700 m, sometimes down to 1000 m and up to 2900 m.
Food and Feeding. Insectivore. Feeds alone, in pairs or in family groups, rarely in mixed-species flocks. Uses short forward or upward sallies to catch insects in dense vegetation close to ground.
Breeding. Birds with enlarged gonads in Mar-Sept. No other relevant information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common or common. Locally common in Colombia; locally fairly common in NW Ecuador. Occurs in Guaramacal National Park, in Venezuela, and almost all Andean national parks in Ecuador. Probably declining because of habitat loss.
Bibliography. Allen (1998), Chapman (1917c), Cuervo & Delgado (2001), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Johnson (2002), Meyer de Schauensee (1982), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman (1994), Schönwetter & Meise (1968), Stotz *et al.* (1996), Zimmer (1940a).

168. **Johnson's Tody-tyrant**
Poecilotriccus luluae

French: Todirostre de Lulu **German**: Lulutodityrann **Spanish**: Titirijí de Lulu
Other common names: Lulu's/Lulu von Hagen's Tody-tyrant

Taxonomy. *Poecilotriccus luluae* Johnson and Jones, 2001, 5 km SE of Corosha, Amazonas, Peru.
Forms a superspecies with *P. ruficeps*. Monotypic.
Distribution. Amazonas and San Martín (Cordillera de Colán and nearby mountains to E), in N Peru.

Descriptive notes. 10 cm; 7·3-7·6 g. Has distinctive bright rufous head, white chin, grey lower nape; olive upperparts, black wings, two narrow yellow wingbars, yellow-white edges of remiges and tertials, olive-brown tail; rufous throat, white band on lower throat; orange-yellow underparts, olive streaking on upper breast and flanks; iris brown; bill black; legs greyish. Sexes alike. Voice. Call a sharp piercing "chick", uttered by both sexes; song, by male only, a short harsh trill, "prrrrt", usually preceded by the "chick" call.
Habitat. Bamboo thickets and edge; also inside forest, usually near bamboo, e.g. in undergrowth of residual subtropical forest or ground strata in cloudforest. Also found in tall or shrubby second growth, e.g. along roads. At 1800-2550 m.
Food and Feeding. Insectivore; hymenopterans recorded in diet. Usually forages in pairs, below 10 m from ground; makes short upward sally-gleans, aerial sallies and perch-gleans.



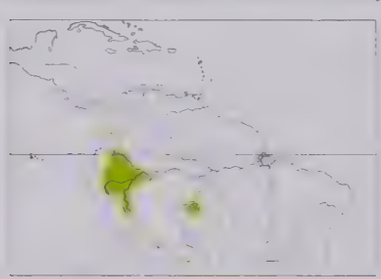
Breeding. Carrying nest material in Dec. No other information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Rare; probably merits listing as threatened species. Restricted to small area of N Peru. Known from only seven localities in Cordillera de Colán, in N extension of Cordillera Central, in nearby mountains known as "Afluente-Abra Patricia" (all in Amazonas), and also from one specimen record 250 km farther S, in Río Abiseo National Park (San Martín). Fairly common 30 km E of Florida de Pomachochas (on road to Rioja, in Amazonas), and E of Abra Patricia (where 1820 km² of forest recently afforded protection). Vulnerable because of its small range, c. 360 km², and estimated population of fewer than 10,000 individuals; probably declining owing to rapid habitat loss caused by logging and conversion to agriculture, although this species may benefit from the overgrowing of abandoned pastures and from the promotion of secondary growth by habitat degradation.
Bibliography. del Carmen & Fjeldså (1999), Clements & Shany (2001), Davis (1986), Etherington (2001), Green (2002c), Hornbuckle (1999), Johnson (2002), Johnson & Jones (2001).

169. White-cheeked Tody-tyrant

Poecilotriccus albifacies

French: Todirostre à face blanche **Spanish**: Titirijí Cariblanco
German: Weißwangen-Todityrann
Other common names: White-cheeked Tody-flycatcher, White-chested Tody-tyrant

Taxonomy. *Todirostrum albifacies* Blake, 1959, left bank of Boca de Río Colorado, Madre de Dios, Peru.
Formerly placed in genus *Todirostrum*. Sometimes considered conspecific with *P. capitalis*. Monotypic.
Distribution. S Madre de Dios and NE Cuzco, in SE Peru.



Descriptive notes. 9·5 cm; 8 g. Male has distinctive rufous crown, white side of head, black nuchal collar extending forwards in two thin black stripes pointing towards eye and malar area; upperparts olive, wings and tail black, white edges of tertials; throat and underparts white, except for black breast side, faintly streaked; iris brown; upper mandible black, lower mandible orange-yellow; legs grey. Female is duller than male, with dark grey neck and cheeks, broad olive wing edgings. Voice. Call, by both sexes, a fast series of sharp "pik" notes, often accelerating, e.g. "pic-picpic-picpicpic".
Habitat. Closely associated with dense *Guadua* bamboo thickets in humid and mainly transitional tropical lowland forest; to 1050 m.
Food and Feeding. Insectivore. Usually forages in pairs, 2-9 m above ground in bamboo thickets, occasionally in adjacent forest; uses upward and forward sally-gleans and perch-gleans to catch insects on bamboo foliage and branches.
Breeding. No information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in South-east Peruvian Lowlands EBA. Uncommon and very local. Occurs above Amazonia Lodge (Cuzco), in Manu National Park and in Tambopata-Candamo Reserved Zone. SE Peruvian lowland forests remain relatively intact, but mining, oil/gas extraction and other development schemes, coupled with associated road-building, human intrusion and selective logging, pose serious future threats; the integrity even of large protected areas, as at Manu and Tambopata-Candamo, is not assured.
Bibliography. Allen (1995), Angehr & Aucca (1997), Clements & Shany (2001), Collar *et al.* (1994), Cracraft (1985), Karr *et al.* (1990), Kratter (1997), Meyer de Schauensee (1982), Parker (1982b), Parker *et al.* (1997), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

170. Black-and-white Tody-tyrant

Poecilotriccus capitalis

French: Todirostre noir et blanc **German**: Schwarzweiß-Todityrann **Spanish**: Titirijí Pío
Other common names: Black-and-white Tody-flycatcher; Tricoloured Tody-tyrant ("*P. tricolor*")

Taxonomy. *Todirostrum capitale* P. L. Sclater, 1857, River Napo, eastern Ecuador.
Formerly placed in genus *Todirostrum*. Sometimes considered conspecific with *P. albifacies*. Described taxon *P. tricolor*, from SW Brazil (Rondônia), has recently been subsumed into present species. Monotypic.
Distribution. S Colombia (SE Nariño, SW Putumayo), E Ecuador, E Peru and SW Brazil (Rondônia).

Descriptive notes. 9·4-9·6 cm; 5·6-8 g. Male has distinctive glossy black upperparts, except for small white supraloral spot and eyering, broad pale yellow edges of tertials, occasionally pale outer web of outermost primary ("*tricolor*"); entirely white below, except for black intruding on upper side of throat and upper breast side (sometimes forming partial pectoral band), pale yellow tinge on flanks and crissum; iris reddish-brown; upper mandible black, lower mandible pale orange-yellow; legs grey. Female has distinctive chestnut cap, buffy lores and eyering, olive upperparts, blackish tail and wings, olive-edged flight-feathers, broad pale yellow tertial edges, grey on side of head and upper breast side, remaining underparts white except for pale yellow flanks and crissum, legs yellow-olive. Voice. Call a fast sharp "tik, t-r-r-r-r-r-r-ew", when agitated more explosive "tk, tk, tk, whey-whey-whey-whuh".
Habitat. Bamboo and tangled viny thickets along streams, roads, and edges of humid lowland and foothill forest; also found in dense undergrowth of second growth without bamboo. Recorded up to 1350 m.
Food and Feeding. Insectivore. Feeds alone or in pairs, independent of mixed flocks, in dense vegetation close to ground; uses short forward or upward sally-gleans.
Breeding. No information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Generally considered rare to uncommon and local; perhaps often overlooked. More common around Kapawi Lodge (Pastaza) and Tiputini Biodiversity Center in Yasuní National Park (Napo), both in Ecuador. Status in SW Brazil requires investigation.
Bibliography. Cardiff (1983), Clements & Shany (2001), Cory & Hellmayr (1927), Cracraft (1985), Forrester (1993), Hilty & Brown (1986), Hornbuckle (1999), Meyer de Schauensee (1982), Parker & Parker (1982), Parker *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg *et al.* (1984), Sick (1993, 1997), Stotz *et al.* (1996), Zimmer (1940a).

171. Buff-cheeked Tody-flycatcher

Poecilotriccus senex

French: Todirostre à joues rousses **Spanish**: Titirijí Carirrosa
German: Ockerwangen-Todityrann
Other common names: Buff-cheeked Tody-tyrant, Plumbeous-crowned/Borba Tody-flycatcher, Todybill

Taxonomy. *Euscarthmus senex* Pelzeln, 1868, Borba, River Madeira, Amazonas, Brazil.
Formerly placed in genus *Todirostrum*. Monotypic.
Distribution. Borba region of lower R Madeira (E Amazonas), in NC Brazil.

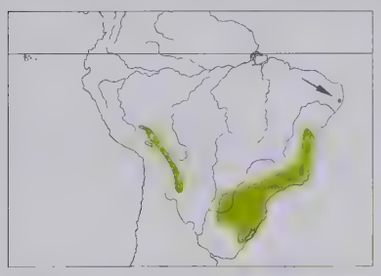
Descriptive notes. 9 cm. Male has slate-grey forehead and forecrown with black spots, dark olive hindcrown with feathers slightly elongated into a rather weak crest; light pinkish-cinnamon loral and facial areas; bright olive upperparts, blackish tail and wings, two conspicuous yellowish-white wingbars, pale edges of flight-feathers; white below, narrow dark streaks on throat, streaks becoming olivaceous and somewhat blurry through breast and upper belly, belly pale yellow; bare parts dark. Female not described. Voice. No information available.
Habitat. Humid forest. Most common in thick, low-stature forest growing at edge of black-water rivers; also present in some physiognomically similar patches of white-sand woodland.
Food and Feeding. Forages mostly in upper third of vegetation, regardless of vegetation height. No other information.
Breeding. No information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Until recently known only from type specimen, collected in 1830 at Borba, on E bank of lower R Madeira. Rediscovered at this site in Oct 1993, and found to be fairly common. Deforestation in Amazonas remains slight; nevertheless, because the area around Borba still supports extensive tracts of intact Amazonian forest and savannas, protection of these is a high priority.
Bibliography. Collar *et al.* (1992), Cory & Hellmayr (1927), Cracraft (1985), Forrester (1993), Hellmayr (1910), Pelzeln (1868-1871), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wege & Long (1995), Whitney & Cohn-Haft (2004).

172. Ruddy Tody-flycatcher

Poecilotriccus russatus

French: Todirostre roussâtre **German**: Rostgesicht-Todityrann **Spanish**: Titirijí Bermejo
Other common names: Russet Tody-flycatcher

Taxonomy. *Euscarthmus russatus* Salvin and Godman, 1884, Mount Roraima, 6000 feet [c. 1830 m], Venezuela.
Formerly placed in genus *Todirostrum*. Forms a superspecies with *P. plumbeiceps*. Monotypic.
Distribution. Tepuis of SE Venezuela (SE Bolívar) and adjacent areas in Guyana and Brazil.



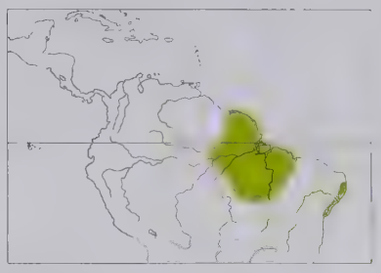
Descriptive notes. 9·5-10·2 cm; 6·5-8·3 g. Male has cinnamon-rufous forehead, sooty-black crown; otherwise dark olive above, two cinnamon-rufous wingbars, greenish-yellow edges of inner remiges; side of head cinnamon-rufous, throat and breast slightly paler, remaining underparts greyish, flanks tinged brownish; iris dark; bill and legs grey to blackish. Female differs from male in having greyer crown. Voice. Call a weak dull "tsuk, sick, tr'r'r'r'r'r'r'r'r'r", sometimes followed by 2-3 shorter trills, or elements given separately, or "tik-a-doo"; other variations when agitated, e.g. "chip-t'b'r'r'r'r, squeeeeo, t'b'r'r'r'r".
Habitat. Dense thickets at edge of humid and wet mossy forest and undergrowth of older second growth, often near streams; also edges of stunted, dense woodland dominated by melastomes (Melastomataceae). At 1200-2500 m.
Food and Feeding. Insectivore. Feeds mostly in pairs, usually not with mixed flocks; makes short forward and upward sallies to catch insects in dense vegetation close to ground.
Breeding. No information.
Movements. Sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Uncommon to common. In Venezuela, fairly common at edge of stunted woodland on Sierra de Lema and occurs also in Canaima National Park; in Guyana, fairly common in forest undergrowth from 1200 m upwards on Mt Roraima and present also on Mt Ayanganna. Tepuis within this species' range are rather unaffected by human disturbance owing to their inaccessibility, but vegetation on the tepuis is especially sensitive to fire and other disturbances; gold-prospectors and uncontrolled tourism have recently had severe adverse impacts locally.
Bibliography. Braun *et al.* (2003), Chapman (1931), Cory & Hellmayr (1927), Cracraft (1985), Forrester (1993), Gilliard (1941), Hilty (2003), Mayr & Phelps (1967), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

173. Ochre-faced Tody-flycatcher

Poecilotriccus plumbeiceps

French: Todirostre gorgeret **German**: Ockergesicht-Todityrann **Spanish**: Titirijí Cabecicanela

Taxonomy. *T[odirostrum] plumbeiceps* Lafresnaye, 1846, "Brésil, Bolivie" = Paraguay.
Formerly placed in genus *Todirostrum*. Forms a superspecies with *P. russatus*. Four subspecies recognized.
Subspecies and Distribution.
P. p. obscurum (J. T. Zimmer, 1940) - SE Peru (from Cuzco) S to E Bolivia (Santa Cruz).
P. p. viridiceps (Salvadori, 1897) - S Bolivia (from Chuquisaca) S to N Argentina (Salta).
P. p. cinereipectus (Novaes, 1953) - NE & CE Brazil (Alagoas, Bahia, SE Minas Gerais, Espírito Santo).
P. p. plumbeiceps (Lafresnaye, 1846) - E Paraguay, SE Brazil (Rio de Janeiro and São Paulo S to Rio Grande do Sul), NE Argentina (Misiones, Corrientes) and NE Uruguay.



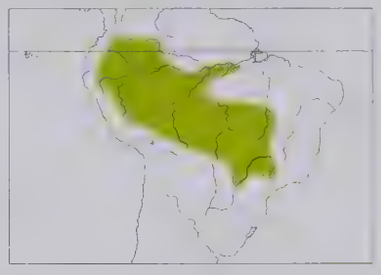
Descriptive notes. 9-9·5 cm; 5·3-6 g. Has buffish-cinnamon forehead, grey crown; otherwise dark olive above, dusky wings with two ochraceous wingbars, ochraceous-edged flight-feathers; side of head buffy cinnamon with dusky auriculars, throat slightly paler, underparts greyish-white; iris brown; bill and legs dark greyish. Sexes alike. Race *viridiceps* has olive tinge on crown, more grey on breast; *obscurum* resembles previous but somewhat darker; *cinereipectus* has more extensive grey on breast. Voice. Call a series of up to five low, sharp "drrr" churrs or rattled "tr-r-r-r-r" trills, sometimes preceded by "tik" note.
Habitat. Dense vine tangles, shrubs, *Chusquea* bamboo or bracken (*Pteridium aquilinum*) thickets at edges of humid forest, and dense undergrowth of second growth. At 750-2750 m.
Food and Feeding. Insectivore. Forages alone or in pairs, usually not with mixed flocks; uses short sallies to catch insects close to ground.
Breeding. Nests in Nov in Argentina and Jan in Paraguay; juveniles observed in Mar. Nest an untidy elongated pear-shaped structure c. 20 cm high and c. 10 cm wide, "visor-shaded" side entrance 3 cm wide, built of dry fibres, including strips of grass and cane leaves, with rounded inner chamber 7·8 × 4·3 cm, sometimes dangling tail 20-30 cm long, suspended usually 1·4-2 m above ground from tip of slender branch in shaded space. Clutch 2-3 eggs; no information on incubation and fledging periods. Brood parasitism by Pavonine Cuckoo (*Dromococcyx pavoninus*) recorded.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Fairly common. Occurs in a number of protected areas, including Pilón Lajas Biosphere Reserve and Madidi National Park, in Bolivia, Caaguazú, San Rafael and Ybycuí National Parks, in Paraguay, Augusto Ruschi Biological Reserve, Fazenda Limoeiro (Minas Gerais), Mata dos Godoy State Park (Paraná), Patrimônio Natural do Caraça Special Reserve and Iguaçu and Itatiaia National Parks, all in Brazil, and Calilegua National Park, in Argentina.
Bibliography. Brooks *et al.* (1993), Canevari *et al.* (1991), Cory & Hellmayr (1927), Cracraft (1985), Darrieu (1987), Di Giacomo & López (1998), Fjeldså (1990), Fjeldså & Krabbe (1990), Fjeldså & Maijer (1996), Hayes (1995), Lowen *et al.* (1996), Meyer de Schauensee (1982), Miserendino (1998), Narosky & Salvador (1998), Narosky & Yzurieta (1993), Pacheco & Whitney (1995), de la Peña (1988), Ridgely & Tudor (1994), Roberson (1996), do Rosário (1996), Sick (1993, 1997), Stotz *et al.* (1996), Teixeira *et al.* (1989), Zimmer (1940a).

174. Smoky-fronted Tody-flycatcher

Poecilotriccus fumifrons

French: Todirostre à front gris **German**: Graustirn-Todityrann **Spanish**: Titirijí Frentigrís

Taxonomy. *Todirostrum fumifrons* Hartlaub, 1853, Bahia, Brazil.
Formerly placed in genus *Todirostrum*. Forms a superspecies with *P. latirostris*. Two subspecies recognized.
Subspecies and Distribution.
P. f. penardi (Hellmayr, 1905) - Surinam and French Guiana.
P. f. fumifrons (Hartlaub, 1853) - lower Amazonian & NE Brazil (C Pará E to S Maranhão and NE Mato Grosso, and coastal region from Paraíba S to N Bahia).
Descriptive notes. 9 cm; 6·7·2 g. Has smoky-grey forehead, olive crown, dull buffish-white supraloral and ocular region; olive upperparts, blackish tail and wings, two prominent buff-yellowish wingbars, yellowish edgings of remiges; whitish throat merging into pale yellow belly, breast with obscure streaks, sides tinged olive; iris light red-brown; bill black, very small white tip; legs plumbeous. Sexes alike. Race *penardi* is very like nominate. Voice. Almost toneless low rattling "kerrr" trill, repeated 5-6 times in quick succession if agitated, usually preceded by one to several "tic" notes.



Habitat. Dense shrubs and thickets in forest edge and overgrown pastures and clearings, also low bushes in open savanna but close to forest edge; to 400 m.
Food and Feeding. Insectivore; recorded prey include coleopterans (Halticinae), hymenopterans, dipterans. Usually forages in pairs, using short sallies to catch insects.
Breeding. No information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Rare to uncommon. In Surinam, fairly common along airstrip at Raleigh Falls Nature Park and occurs also in Sipaliwini Savanna Nature Reserve. Present also in EMBRAPA Experimental Station and Pedra Branca/Fazenda Bananeira Reserve (Alagoas), in Brazil.
Bibliography. Cory & Hellmayr (1927), Forrester (1993), Haverschmidt (1968), Haverschmidt & Mees (1994), Meyer de Schauensee (1982), Ridgely & Tudor (1994), Sick (1993, 1997), Schönwetter & Meise (1968), Stotz *et al.* (1996), Tostain *et al.* (1992).

175. Rusty-fronted Tody-flycatcher

Poecilotriccus latirostris

French: Todirostre à front roux **German**: Rostzügel-Todityrann **Spanish**: Titirijí Frentirrojo

Taxonomy. *Euscarthmus latirostris* Pelzeln, 1868, Borba, River Madeira, Amazonas, Brazil.
Formerly placed in genus *Todirostrum*. Forms a superspecies with *P. fumifrons*. Seven subspecies recognized.
Subspecies and Distribution.
P. l. mituense (Olivares, 1965) - E Colombia (around Mitú, Vaupés).
P. l. caniceps (Chapman, 1924) - S Colombia (W Caquetá) E to NW Brazil (E to Tefé) and S to E Ecuador and E Peru.
P. l. senectus (Griscom & Greenway, 1937) - N Brazil N of Amazon (NE Amazonas E to NW Pará).
P. l. latirostris (Pelzeln, 1868) - C Amazonian Brazil from upper R Juruá and R Purús E to Parintins.
P. l. austroriparius (Todd, 1952) - right bank of R Tapajós, in W Pará (Brazil).
P. l. mixtus (J. T. Zimmer, 1940) - SE Peru (from N Puno) S to NW Bolivia (La Paz, Beni, Cochabamba).
P. l. ochropterus (J. A. Allen, 1889) - S Brazil (Mato Grosso S to N São Paulo).

Descriptive notes. 9·4-9·5 cm; 8·1-9 g. Nominate race has rusty-buff forehead and side of head, brownish-grey crown and neck, olive upperparts, dusky tail and wings, two ochraceous wingbars, yellowish-edged flight-feathers and bend of wing; greyish-white below, tinged olive on breast and sides; iris dark; bill and legs greyish. Sexes alike. Race *caniceps* has darker grey crown, richer buffy facial area; *ochropterus* has pale brownish crown, golden tinge to upperparts; other races all fairly similar to nominate. Voice. Frog-like call a short, dry, low-pitched rattled trill, "tik, trrrr, trrrr", sometimes just the "tik" note.
Habitat. Dense thickets and overgrown shrubby tangles in undergrowth of young secondary growth, overgrown pastures and clearings, and along humid forest edge and riverbanks; also on lowland river islands. To 1100 m.
Food and Feeding. Insectivore. Usually forages in pairs, not accompanying mixed flocks; uses short forward and upward sallies to catch insects in dense vegetation close to ground.
Breeding. Birds in breeding condition recorded in Jun. No other information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Uncommon to locally common. Common around Leticia, in extreme SE Colombia. Occurs in numerous national parks and other protected areas throughout its range, within which much of its habitat remains in relatively pristine condition.
Bibliography. Allen (1995), Bates & Parker (1998), Cory & Hellmayr (1927), Dubs (1992), Gyldenstolpe (1950), Hennessey, Herzog & Sagot (2003), Hilty & Brown (1986), Karr *et al.* (1990), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Schulenberg *et al.* (2001), Sick (1993, 1997), Stotz *et al.* (1996), Willis & Oniki (1990), Zimmer (1930, 1940a).

176. **Slate-headed Tody-flycatcher**

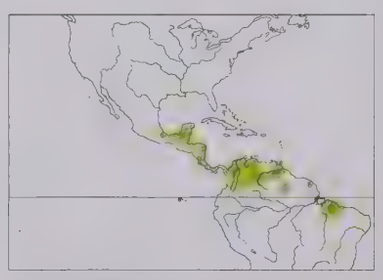
Poecilotriccus sylvia

French: Todirostre de Desmarest **German**: Graukopf-Todityrann **Spanish**: Titirijí Gris
Other common names: Slaty Tody-flycatcher

Taxonomy. *Todus sylvia* Desmarest, 1806, locality unknown = probably French Guiana. Formerly placed in genus *Todirostrum*. Five subspecies recognized.

Subspecies and Distribution.

P. s. schistaceiceps (P. L. Sclater, 1859) - S Mexico (from S Veracruz) S to Panama (E to Canal Zone).



P. s. superciliaris (Lawrence, 1871) - N, W & C Colombia (Caribbean coast, Magdalena and Cauca Valleys, in middle Dagua Valley on Pacific Andean slope, and S to W Meta on E slope).

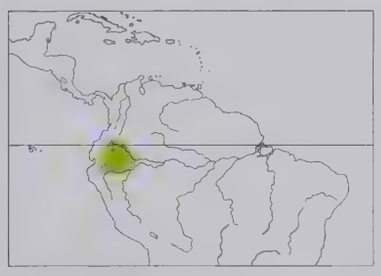
P. s. griseolus (Todd, 1913) - N & C Venezuela and extreme E Colombia.

P. s. sylvia (Desmarest, 1806) - extreme N Brazil (along R Branco), Guyana and French Guiana.

P. s. schulzi (Berlepsch, 1907) - NE Brazil (SE Pará E to Piauí).

Descriptive notes. c. 9-10 cm; 6·7-8·5 g. Nominate race has grey crown and nape, white "spectacles" formed by white supraloral line and eyering, latter broken at front by grey lores; olive

upperparts, blackish wings, two bold yellow wingbars, yellowish-edged inner flight-feathers; greyish-white below, streaked greyish on lower throat and breast, flanks tinged olive; iris dark brown, sometimes pale yellow, grey or white; bill black; legs light bluish-grey. Sexes alike. Juvenile has olive crown and nape not distinctly different from back, buffy-tinged wingbars, paler and greyer underparts without streaking. Races vary little: *schulzi* is darker than nominate, has much greyer breast, and more ochraceous wingbars; *schistaceiceps* has pale yellow sides, flanks and crissum, reddish-brown, tawny, purplish or pale yellow iris; *superciliaris* and *griseolus* resemble nominate but both tend to be somewhat darker overall. Voice. Call is a soft, low, gravelly "tic" or "trup", sometimes repeated; a nasal descending "trrrr" trill sometimes added, and trill also given alone at times, sounding very insect-like or frog-like; also utters an excited "tíc-a-turr".



Habitat. Dense thickets along forest edges and overgrown shrubby roadsides, and shrubby and vine-tangled young second growth in overgrown pastures and clearings; also understorey of gallery forest and dry woodlots. Lowlands to 1100 m.
Food and Feeding. Mainly arthropods; fruit also taken. Recorded foods ants and small wasps (Hymenoptera), homopteran (e.g. leafhoppers) and heteropteran bugs, beetles (Coleoptera), flies (Diptera), orthopterans, lepidopterans, spiders (Araneae). Usually forages in pairs; uses short forward and upward sallies to catch prey in dense vegetation close to ground, sometimes also high in canopy.
Breeding. Nests found in Mar in Costa Rica and Jun in Venezuela; eggs in Apr-Jun and birds in breeding condition in Jan-Aug. Elongated nest with side entrance, built of moss, grasses, plant epidermis and fibres, suspended usually below 3 m from tip of slender branch in free space covered above by thick foliage in thicket. Clutch 2 eggs; no information on incubation period; nestling period c. 18-21 days.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Uncommon to locally common; perhaps often overlooked. Fairly common in Tocumen area of Panama. Occurs in many national parks and other protected areas throughout its range. Tolerant of converted habitat; probably benefits from deforestation if forest subsequently allowed to regenerate.
Bibliography. Anon. (1998a), Binford (1989), Cory & Hellmayr (1927), Cracraft (1985), Haffer (1975), Hilty (2003), Hilty & Brown (1986), Howell & Webb (1995a), Karr (1971), Lee Jones (2004), Miller (1947), Monroe (1968), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Schönwetter & Meise (1968), Sherry (1983b, 1984), Sick (1993, 1997), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Thomas (1982), Tostain *et al.* (1992), Wetmore (1972).

177. **Golden-winged Tody-flycatcher**

Poecilotriccus calopterus

French: Todirostre à ailes d'or **German**: Goldflügel-Todityrann **Spanish**: Titirijí Alidorado

Taxonomy. *Todirostrum calopterum* P. L. Sclater, 1857, River Napo, Ecuador.
Formerly placed in genus *Todirostrum*. Forms a superspecies with *P. pulchellus*, and often considered conspecific. Monotypic.
Distribution. S Colombia (SE Nariño, W Putumayo), E Ecuador and NE Peru (Loreto).

Descriptive notes. 8·9-9·7 cm; 5·9-8·7 g. Has black head, olive upperparts, black wings, distinctive pattern of chestnut shoulder patch bordered by wide golden-yellow wingband, and yellow-edged tertials; tail black; white throat contrasting with bright yellow underparts; iris dark brown; bill black; legs grey. Sexes alike. Juvenile undescribed. Voice. Mechanical, gravelly, rapid and descending "tsk-t-t-t-t-t-t", "dre'd'd'd'deu" or "p-drrrew", repeated every 5-10 seconds, sometimes given as duet.
Habitat. Undergrowth of humid lowland forest and foothill forest and edge, and overgrown dense bushy second growth in abandoned pastures and clearings; recorded up to 1450 m.
Food and Feeding. Insects recorded. Usually forages in pairs, and not joining mixed flocks; uses short forward and upward sallies to catch insects in dense vegetation close to ground.
Breeding. No information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Upper Amazon-Napo Lowlands EBA. Rare to locally fairly common. Fairly common at Jatun Sacha Biological Station, and occurs also at Kapawi and La Selva Lodges and Archidona Natural Reserve, all in Ecuador. Although forests in its range are reasonably intact, deforestation in E Ecuador and parts of SE Colombia has been quite extensive, with further threats emerging from new oil fields and associated road-building and human intrusion.
Bibliography. Cardiff (1983), Cracraft (1985), Curson & Lowen (2000), Hilty & Brown (1986), Meyer de Schauensee (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

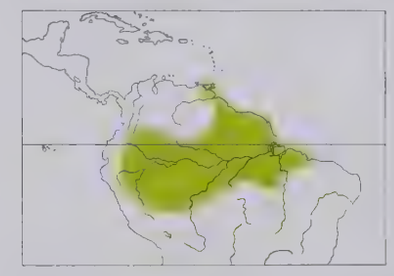
178. **Black-backed Tody-flycatcher**

Poecilotriccus pulchellus

French: Todirostre à dos noir **German**: Weißzügel-Todityrann **Spanish**: Titirijí Dorsinegro

Taxonomy. *Todirostrum pulchellum* P. L. Sclater, 1874, Peruvia alta, Cosñipata, Cuzco, Peru.
Formerly placed in genus *Todirostrum*. Forms a superspecies with *P. calopterus*, and often considered conspecific. Monotypic.
Distribution. SE Peru (E Cuzco, N Puno).

Descriptive notes. 9-9·5 cm; 7·2-8·7 g. Male has black head and upperparts, with very small white spot or spots behind eye, and short white submoustachial stripe; black wings,with distinctive pattern of dull chestnut shoulder patch bordered by wide golden-yellow wingband, and yellow-edged tertials; tail black, with pale yellow outer web on outer pair of feathers; throat white, rest of underparts bright yellow; iris usually dark; bill black; legs grey. Female differs from male in having white loral spot and dark olive back. Juvenile not described. Voice. Rapid mechanical notes, similar to those of *P. calopterus*.
Habitat. Inhabits dense low shrubby areas along edges of humid lowland and foothill forest, at elevations of 300-1100 m.
Food and Feeding. Insects recorded. Usually forages in pairs, not joining mixed flocks; uses short forward and upward sallies to catch prey in dense vegetation close to ground.
Breeding. No information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Restricted-range species: present in Southeast Peruvian Lowlands EBA. Rare to uncommon. Uncommon along lower Manu road, lower Shintuya-Paucartambo road, and at Amazonia Lodge. SE Peruvian lowland forests remain relatively intact, but mining, oil extraction and other development schemes, with associated road-building and human intrusion, pose serious future threats; integrity even of large protected areas, such as Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, is not assured.
Bibliography. Clements & Shany (2001), Cracraft (1985), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer (1940a).



Genus *TODIROSTRUM* Lesson, 1831

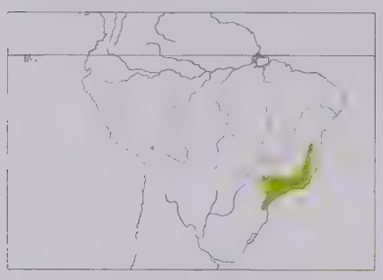
179. **Spotted Tody-flycatcher**

Todirostrum maculatum

French: Todirostre tacheté **German**: Fleckenbrust-Todityrann **Spanish**: Titirijí Moteado

Taxonomy. *Todus maculatus* Desmarest, 1806, Cayenne, French Guiana.
Five subspecies recognized.
Subspecies and Distribution.
T. m. amacurense Eisenmann & Phelps, Jr, 1971 - NE Venezuela, Trinidad and N Guyana.
T. m. maculatum (Desmarest, 1806) - Surinam, French Guiana and NE Brazil (from R Xingú E to Amapá, E Pará and N Maranhão).
T. m. signatum P. L. Sclater & Salvin, 1881 - SE Colombia (Caqueta, Amazonas), W Brazil (W Amazonas, W Rondônia), E Ecuador, E Peru and NW Bolivia.
T. m. annectens J. T. Zimmer, 1940 - N Brazil (R Branco and NE Amazonas S to mouth of R Negro).
T. m. diversum J. T. Zimmer, 1940 - C Brazil from R Negro E to R Jamundá and, S of Amazon, from E Amazonas (Tefé and upper R Madeira) E to right bank of R Tapajós.

Descriptive notes. 8·9-10·2 cm; 6·4-8·3 g. Nominate race has grey head with some black and white crown streaks, small white supraloral spot; olive upperparts, wings brownish-black, wing-coverts edged and tipped yellowish (sometimes forming indistinct wingbars), yellowish-edged flight-feathers; tail brownish-black, outer webs of outer feathers with yellow-white margins; throat and upper breast white with distinctive rather narrow black streaks, remaining underparts yellow, streaked dark olive on sides; iris yellowish-orange, sometimes grey or brown; bill black, some white on lower mandible; legs pinkish-grey. Sexes alike. Immature is more narrowly and lightly streaked. Races vary little: *amacurense* and *signatum* have sooty-black forecrown. Voice. Clear, sharp and loud "tee" or "peek", repeated up to 12 times at 2 per second, often immediately answered by mate, thus sounding like "peek-peek" notes.
Habitat. Usually associated with wet areas, e.g. dense shrubby thickets and second growth along edges of mangroves (*Avicennia nitida*), oxbow lakes, creeks, streams, rivers and river islands, also shrubby second growth in abandoned pastures and clearings; also found in taller trees in riparian areas or light woodland, even in gardens around single houses or in towns. Recorded also in young *Cecropia* mixed with grass and openings. Lowlands to 500 m.
Food and Feeding. Recorded foods include arachnoids, flies (Diptera), termites (Isoptera), butterflies (Lepidoptera). Usually in pairs, independent of mixed flocks. Forages mostly in dense vegetation close to ground, also in more open vegetation fairly high in trees; uses short forward and upward sallies to catch prey, with audible snap on capture.
Breeding. Eggs recorded in all months; juveniles with adults in Aug in Colombia. Nest built by both sexes, taking c. 2 weeks, an untidy elongated pouch with roofed side entrance, made of dead grasses and other plant material, bound with spiderweb, lined with plant wool, hanging from drooping branch, usually below 3 m, and regularly (11 of 27 cases) near wasp nest (e.g. of *Polybia occidentalis* and *Nectarina bilineolata*). Clutch 1-2 eggs; incubation by female alone, period 16-21 days; chicks fed by both parents, nestling period c. 15-19 days.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Fairly common to common. Occurs in many national parks and other protected areas throughout its fairly large range. Able to thrive in secondary and converted habitats.
Bibliography. Bangs & Penard (1918), Bennett (1986), Clements & Shany (2001), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), ffrench (1991), ffrench & Kenefick (2003), Friedmann (1948), Haverschmidt (1955, 1968), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Marceliano (1982), Meyer de Schauensee (1982), Novaes (1978a), Oren & Parker (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1995, 1997), Schönwetter & Meise (1968), Schubart *et al.* (1965), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Temple (2002), Tostain *et al.* (1992), Walther (2004), Zimmer (1940a).



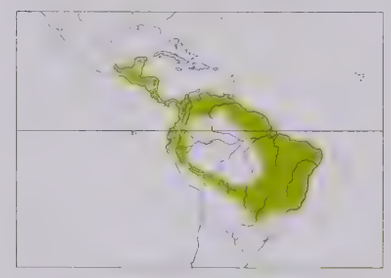
180. **Grey-headed Tody-flycatcher**

Todirostrum poliocephalum

French: Todirostre à tête grise **German**: Gelbzügel-Todityrann **Spanish**: Titirijí Cabecigrís
Other common names: Yellow-lored Tody-flycatcher

On following pages: 181. Common Tody-flycatcher (*Todirostrum cinereum*); 182. Maracaibo Tody-flycatcher (*Todirostrum viridanum*); 183. Painted Tody-flycatcher (*Todirostrum pictum*); 184. Yellow-browed Tody-flycatcher (*Todirostrum chrysocrotaphum*); 185. Black-headed Tody-flycatcher (*Todirostrum nigriceps*).

Taxonomy. *T[odus] poliocephalus* Wied, 1831, Rio de Janeiro, Brazil.
Monotypic.
Distribution. SE Bahia and Minas Gerais S to Santa Catarina, in SE Brazil.



Descriptive notes. 8·8-10·2 cm. Has glossy black forecrown and ocular region, distinctive large bright yellow supraloral spot, slate-grey hindcrown, olive upperparts; wings black, yellow-edged wing-coverts and flight-feathers; tail rounded, olive; throat and underparts bright yellow; iris orange-yellow; bill black; legs bluish-grey. Sexes alike. Juvenile undescribed. VOICE. Call a simple sharp "cheep, chip-chip".
Habitat. Shrubby humid-forest edge and adjacent clearings and gardens, to 1200 m.
Food and Feeding. Insects. Usually in pairs, sometimes alone, generally independent of mixed flocks. Forages in dense vegetation close to ground, also in more open canopy of smaller trees; uses short forward and upward sallies to catch insects, with audible snap on capture.
Breeding. No relevant published information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Uncommon to common. Occurs in Itatiaia, Serra da Canastra and Tijuca National Parks, Augusto Ruschi Biological Reserve and several other protected areas within its rather small range. Not dependent on intact forest; considered unlikely to become at risk in immediate future.
Bibliography. Bauer & Pacheco (2000), Cory & Hellmayr (1927), Cracraft (1985), Develey (2004), Forrester (1993), Guix *et al.* (1992), Meyer de Schauensee (1982), Pacheco & Whitney (1995), Ridgely & Tudor (1994), do Rosário (1996), Schönwetter & Meise (1968), Sick (1993, 1997), Stotz *et al.* (1996), Venturini *et al.* (2001).

181. Common Tody-flycatcher

Todirostrum cinereum

French: Todirostre familier **German**: Graugelb-Todityrann **Spanish**: Titirijí Común
Other common names: Black-fronted Tody-flycatcher

Taxonomy. [*Todus*] *cinereus* Linnaeus, 1766, Surinam.
Probably forms a superspecies with *T. viridanum*. Eight subspecies recognized.
Subspecies and Distribution.
T. c. virididorsale Parkes, 1976 - SC Veracruz (drainage of R Papaloapan) and adjacent N Oaxaca, in S Mexico.
T. c. finitimum Bangs, 1904 - S Mexico (S Veracruz) S to NW Costa Rica.
T. c. wetmorei Parkes, 1976 - C & E Costa Rica and Panama.
T. c. cinereum (Linnaeus, 1766) - Colombia (except SW), Venezuela (except NW), the Guianas and NE Brazil.
T. c. sclateri (Cabanis & Heine, 1859) - SW Colombia (SW Cauca, Nariño), W Ecuador and NW Peru (Tumbes, Piura, Lambayeque).
T. c. peruanum J. T. Zimmer, 1930 - E Ecuador and E Peru (Loreto S to Cuzco).
T. c. cearae Cory, 1916 - E Brazil (E Pará E to Ceará and Alagoas, S to N Bahia).
T. c. coloreum Ridgway, 1906 - N Bolivia, N Paraguay, S & SE Brazil (S Mato Grosso E to Espírito Santo and São Paulo) and NE Argentina (Misiones).

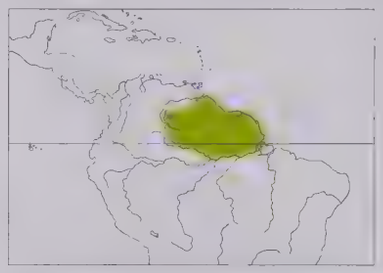
Descriptive notes. 8·8-10·2 cm; 4·4-8 g. Nominate race male has glossy black forecrown, lores and ocular region, slate-grey hindcrown and upper back giving way to dark olive rear upperparts; wings black, yellow edges and tips of wing-coverts and flight-feathers; tail rounded, black, outer feathers with white tips; throat and underparts bright yellow; iris yellowish to white; bill black, base of lower mandible fleshy white; legs bluish-grey. Female differs in having head greyer, entire lower mandible fleshy white. Juvenile has crown and cheeks dark grey, yellowish wing markings buffy-tinged, paler underparts, dark iris. Race *finitimum* has greyish-green upperparts; *virididorsale* and *wetmorei* have brighter green upperparts; *sclateri* has white throat, sometimes dark iris; *peruanum* resembles nominate, but has dark iris; *coloreum* has paler grey nape, more olive upperparts; *cearae* resembles previous. VOICE. Shrill short single, double or triple note, "tchik", "tik", "teet" or "peept", or series of up to 12 "p-peept" notes; also high-pitched "te'e'e'e'e'et" trill, usually repeated several times, often answered by mate, and sharp "tic" repeated up to 110 times per minute at dawn during nesting season; begging note of fledglings long drawn-out "pseeee, pseeee".
Habitat. All kinds of open and semi-open areas and edges of forest, mangroves and rivers, e.g. lighter woodland, *restinga*, second growth, overgrown shrubby clearings and pastures, shady plantations, open groves, savanna thickets, hedgerows, orchards, gardens, cultivated areas, wasteland; avoids densely forested regions. To 2000 m.
Food and Feeding. Arthropods, including small ants and parasitoid wasps (Hymenoptera), spiders (Araneae), lepidopterans, beetles (Coleoptera), bugs (both Homiptera and Heteroptera), flies (Diptera), damselflies (Zygoptera) and orthopterans; fruit also taken. Usually in pairs or family groups, but sometimes alone, and generally independent of mixed flocks. Forages in dense vegetation close to ground, also in more open mid-level and canopy of trees; tail almost perpetually cocked and wagged. Items taken by gleaning and in short forward and upward sallies, with audible snap on capture.
Breeding. Eggs Dec-Oct. Nest built by both sexes, taking up to 37 days, an untidy elongated pouch with rounded chamber, dangling "tail" and visor-shaded side entrance, made from fine fibres, mosses, grasses and many other plant materials, bound with spiderweb, lined with fine grass, feathers and plant/seed down; suspended from drooping branch (or even telephone wire), usually 1-5 m but sometimes 30 m up, and sometimes near wasp nest. Clutch 2-3 eggs; incubation by female alone, period c. 18 days; chicks fed by both parents, nestling period c. 17-18 days, fledgings partially dependent on parents for up to 43 days.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Fairly common to abundant. Occurs in numerous national parks and other protected areas throughout its large range. Survives well in converted and secondary habitats; benefits from deforestation, spreading into clearings and plantations, where it is usually common.
Bibliography. Anon. (1998a), Bennett (1986), Binford (1989), Bosso (2001), Clements & Shany (2001), Cory & Hellmayr (1927), Cruz & Andrews (1989), Haffer (1975), Haverschmidt (1968, 1978), Haverschmidt & Mees (1994), Hayes (1995), Henderson (2002), Hilty (1997, 2003), Hilty & Brown (1986), Howell & Webb (1995a), Lee Jones (2004), Miller (1963), Monroe (1968), Olson (1997), Parkes (1976), Pople *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1907), Robbins *et al.* (1985), Rodrigues & Santos (2000), Salaman (1994), Schönwetter & Meise (1968), Schuchmann (1985), Sherry (1983b, 1984), Sick (1993, 1997), Silveira *et al.* (2003), Skutch (1930), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Tostain *et al.* (1992), Wetmore (1972), Williams & Tobias (1994), Willis (1980), Zimmer (1930, 1940a).

182. Maracaibo Tody-flycatcher

Todirostrum viridanum

French: Todirostre du Maracaïbo **Spanish**: Titirijí de Maracaibo
German: Kurzschwanz-Todityrann
Other common names: Short-tailed Tody-flycatcher

Taxonomy. *Todirostrum viridanum* Hellmayr, 1927, River Aurare, 12 miles [c. 19 km] south of Altagracia, Zulia, Venezuela.
Probably forms a superspecies with *T. cinereum*. Monotypic.
Distribution. Coastal Zulia and Falcón, in NW Venezuela.



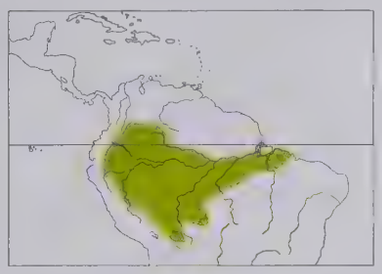
Descriptive notes. 9-10·2 cm. Has black lores, ocular region and forecrown, semi-concealed yellowish-white coronal mark, grey hindcrown; distinctive yellowish-white marks on forehead and supraloral region; upperparts pale olive, wings black, broad buff-yellow edges and tips of wing-coverts and edges of flight-feathers; tail markedly short, black with white tips and edges; pale yellow below, flanks tinged buffy; iris dark, sometimes yellowish-white; upper mandible black, lower mandible pinkish; legs grey. Sexes alike. Juvenile undescribed. VOICE. Song a series of c. 6 sharp "seek" notes.
Habitat. Semi-arid and arid scrub, thickets and woodland (usually with *Acacia*, *Cercidium*, *Cardon* and *Opuntia*); also tropical deciduous forest and gallery forest. To 200 m.
Food and Feeding. Arthropods. Forages usually in pairs, sometimes alone, in dense scrubby vegetation close to ground, sometimes also a little higher in smaller trees. Prey caught by short forward and upward sallies.
Breeding. No information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Caribbean Colombia and Venezuela EBA. Fairly common. Although there are still large expanses of suitable habitat within the species' small range, none is protected; furthermore, substantial areas have been destroyed, principally around L Maracaibo, by overgrazing, firewood-gathering, tourist development and pollution.
Bibliography. Collar & Andrew (1988), Collar *et al.* (1994), Cory & Hellmayr (1927), Cracraft (1985), Hilty (2003), Parker *et al.* (1996), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996).

183. Painted Tody-flycatcher

Todirostrum pictum

French: Todirostre peint **German**: Schwarzflecken-Todityrann **Spanish**: Titirijí Pintado

Taxonomy. *Todirostrum pictum* Salvin, 1897, Annai, Guyana.
Forms a superspecies with *T. chrysocrotaphum* and *T. nigriceps*, and all sometimes treated as conspecific. Monotypic.
Distribution. SE Venezuela (Amazonas, Bolívar), the Guianas and adjacent N Brazil.



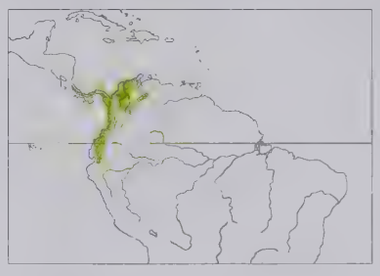
Descriptive notes. 9-10·2 cm; 6-8 g. Has glossy black head, white supraloral spot, long white submoustachial stripe; small yellow neckband, olive back and rump; wings black, two yellow wingbars, yellow feather edges; tail black, olive outer edges; throat whitish with black streaks, bright yellow underparts, black streaks on upper breast; iris dark brown or yellow; bill black; legs blackish. Sexes alike. Juvenile undescribed. VOICE. Call "chevik" or "pi-pik"; song 8-12 sharp, piercing "peek" notes at c. 2 per second; also a penetrating whistle, "teeng-teeng-teeng-teeng".
Habitat. Canopy of tall humid *terra firme*, *várzea* and tropical dry forest, forest borders and tall second growth; also adjacent clearings and plantations with scattered tall trees. To 400 m.
Food and Feeding. Arthropods, including e.g. flies (Diptera). Forages alone or in pairs, rarely with mixed-species flocks, in high outer-canopy foliage and along forest edges. Makes short forward and upward sallies.
Breeding. Oct in Surinam. Nest built by both sexes, an untidy elongated pouch with dangling "tail" and side entrance, in one case suspended from drooping branch high in garden tree near wasp (Hymenoptera) nest; nests usually sited higher up than those of congeners. Apparently no other relevant information.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Uncommon to fairly common; often overlooked, most frequently located by voice.
Bibliography. Bangs & Penard (1918), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1927), Friedmann (1948), Haverschmidt & Mees (1994), Hilty (2003), Naka (2004), Novaes (1978a), Ridgely & Tudor (1994), Schönwetter & Meise (1968), Sick (1993, 1997), Snyder (1966), Stotz *et al.* (1996), Thiollay & Jullien (1998), Tostain *et al.* (1992).

184. Yellow-browed Tody-flycatcher

Todirostrum chrysocrotaphum

French: Todirostre bridé **German**: Goldbrauen-Todityrann **Spanish**: Titirijí Cejiamarillo

Taxonomy. *Todirostrum chrysocrotaphum* Strickland, 1850, Peru.
Forms a superspecies with *T. pictum* and *T. nigriceps*, and all sometimes treated as conspecific. Five subspecies recognized.
Subspecies and Distribution.
T. c. guttatum Pelzeln, 1868 - Colombia (S from W Meta and Guainía) and NW Brazil S to E Ecuador and extreme NE Peru (NE Loreto).
T. c. chrysocrotaphum Strickland, 1850 - N Peru and W Brazil (E to Tefé, in C Amazonas).
T. c. neglectum Carriker, 1932 - E Peru, SW Brazil and N Bolivia.
T. c. simile J. T. Zimmer, 1940 - left bank of R Tapajós, in W Pará (NC Brazil).
T. c. illigeri (Cabanis & Heine, 1859) - NE Brazil from right bank of R Tapajós E to N Maranhão.



Descriptive notes. 8·6-10·2 cm; 7 g. Distinctive, with broad yellow postocular stripe on glossy black head. Nominate race has white supraloral spot, olive upperparts, black wings with two yellow wingbars and yellow edgings; short black tail; bright yellow underparts, black streaks on malar area and across breast; iris variable usually dark, sometimes pale; bill blackish; legs bluish-grey. Sexes alike. Juvenile undescribed. Race *guttatum* has white chin, heavier black streaks on malar area and breast; *neglectum* is somewhat paler than nominate, no streaks below, lacks supraloral spot; *simile* resembles previous but with white supraloral spot; *illigeri* lacks supraloral spot but has black malar stripe. Voice. Call a loud series of usually 8-12 sharp, evenly spaced "pik", "tsip" or "pip" notes.
Habitat. Canopy and edge of *terra firme* and *várzea* forest and taller second growth, adjacent shrubby clearings with scattered large trees; to 1400 m.
Food and Feeding. Insects recorded. Usually in pairs, sometimes alone; rarely with mixed-species flocks. Forages high up in foliage of outer canopy; also along forest edge, when sometimes descends lower; tail usually held cocked. Makes short forward and upward sallies.
Breeding. Few data. Nest found in Jun in Colombia, 4-5 m above ground in second growth; another in Jul in Ecuador, 35 m up in emergent tree in forest. In Ecuador, 3 successive nests built in same tree, Jul, Apr and Jul; all c. 35-40 m up in large kapok (*Ceiba*) tree; hanging globular nests, lined with kapok seed down; adult bringing food to second nest in late May; latter 2 nests were situated in close proximity to a paper wasp (Vespidae) nest.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common, but often overlooked. Occurs in numerous protected areas, including many national parks, throughout its rather large range. Much of its habitat remains in relatively pristine condition.
Bibliography. Allen (1995), Bates & Parker (1998), Blake (1962), Cory & Hellmayr (1927), Greeney *et al.* (2004), Haffer (1997b), Haverschmidt (1968), Hilty & Brown (1986), Meyer de Schauensee (1982), Oren & Parker (1997), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1995, 1997), Schönwetter & Meise (1968), Schulenberg *et al.* (2001), Sick (1993, 1997), Stotz *et al.* (1996), Traylor (1958), Zimmer (1940a).

185. Black-headed Tody-flycatcher

Todirostrum nigriceps

French: Todirostre à tête noire **German**: Schwarzkopf-Todityrann **Spanish**: Titirijí Cabecinegro

Taxonomy. *Todirostrum nigriceps* P. L. Sclater, 1855, Sierra Nevada de Santa Marta, Colombia.
Forms a superspecies with *T. pictum* and *T. chrysocrotaphum*, and all sometimes treated as conspecific. Monotypic.
Distribution. E Costa Rica, Panama, N & W Colombia, extreme W Venezuela and W Ecuador.

Descriptive notes. 8·10·2 cm; 6·6·5 g. Distinctive. Has glossy black crown and side of head contrasting with white throat and yellowish-olive upperparts; sometimes narrow white supraloral spot; wings black, two yellow wingbars and yellow edgings; tail rather short, black; underparts bright yellow; iris dark brown; bill black; legs blue-grey to blackish. Sexes alike. Juvenile has duller black head, yellow-tinged throat, paler yellow underparts, olive-tinged wing markings. Voice. Call a lively single or double "chip", "peep" or "pik"; song a slow series of usually 5-8 (up to 12) high-pitched sharp "tsip" or "jyip" notes, the first somewhat lower, final ones accelerating and increasing slightly in volume; incubating female utters soft trill.
Habitat. Canopy and edge of humid forest and second growth, and adjacent plantations, clearings and pastures with scattered tall trees; to 1500 m.
Food and Feeding. Arthropods, e.g. ants and parasitoid wasps (Hymenoptera), flies (Diptera), damselflies (Zygoptera), bugs (both Heteroptera and Homoptera), lepidopterans, beetles (Coleoptera), spiders (Araneae). Alone or in pairs, rarely with mixed-species flocks. Forages inside dense foliage of upper mid-level to high canopy; also along forest edge, when sometimes found lower. Prey captured in short forward and upward sallies; ants also taken from extrafloral nectaries and *Cordia* twig nodes.
Breeding. Nest found in Jun and birds taken in breeding condition in Feb, in Colombia; nest found in Aug, in Panama. Nest is an untidy short pouch with dangling "tail" and visor-shaded side entrance, made from plant fibres and lined with seed down, suspended from drooping branch 3-15 m up, almost always near a wasp nest. Clutch 1 egg; no information available on incubation and fledging periods.
Movements. Probably sedentary.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common, but probably often overlooked. Occurs in Rancho Naturalista and Río Negro Jaguar Reserve, in Costa Rica; in Darién National Park, in Panama; common in Tayrona National Park and fairly common in Río Claro Reserve, in Colombia; in Ecuador, found in Río Palenque Science Centre and also in Manta Real (designated for protection), near Guayaquil (Azuay).

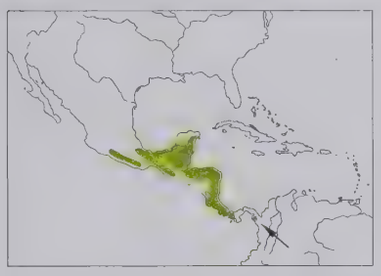
PLATE 28

inches 3

cm 8

Genus *RHYNCHOCYCLUS*



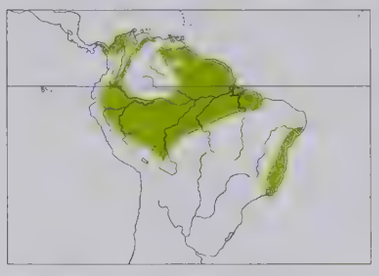
Cabanis & Heine, 1859

186. **Eye-ringed Flatbill**

Rhynchocyclus brevirostris

French: Platyrhynque à bec court **Spanish**: Picoplano de Anteojos
German: Augenring-Breitschnabeltyrann

Taxonomy. C[*yclorhynchus*] *brevirostris* Cabanis, 1847, Jalapa, Veracruz, Mexico.
Formerly considered conspecific with *R. pacificus*. Three subspecies recognized.
Subspecies and Distribution.
R. b. pallidus Binford, 1965 - Pacific slope of Oaxaca (Putla and Minitán E to Pluma Hidalgo), probably also in Guerrero, in S Mexico.
R. b. brevirostris (Cabanis, 1847) - S Mexico E of Isthmus of Tehuantepec (E Veracruz and E Oaxaca E to Yucatán Peninsula) S to W Panama (Chiriquí, Veraguas).
R. b. hellmayri Griscom, 1932 - mountains of E Panama and extreme NW Colombia (Cerro Tacarcuna, in NW Chocó).



Descriptive notes. 15-17 cm; 21-23 g. Large-headed flycatcher. Male has olive-green head and upperparts, conspicuous white eyering, faint dark smudge below eye, greyish lores and cheeks, paler greyish patch on auriculars bordered behind by dusky patch; wings and tail dusky with paler yellow-olive edgings, stiffened comb-like barbs on outer primaries; tail often appears notched; throat and chest dull or dusky olive-green, becoming paler with pale greyish or yellowish shaft streaks on lower breast and sides, belly pale yellow; iris dark; bill large, broad and flat, upper mandible black, lower mandible pale horn; legs grey. Differs from *R. olivaceus* in bolder white eyering, brighter yellow on wings. Female lacks comb-like barbs on outer primaries. Juvenile is similar but with brighter yellow on belly and edges of wing feathers, more coarse streaking on sides, little or no breast streaking and dusky on auriculars. Races differ little: *pallidus* is slightly paler than nominate; *hellmayri* is darker above and below than nominate, with duller yellow belly. Voice. Variety of notes uttered 1-5 times, including high-pitched squeaky and rising "zweeip" or "sweeip", a cicada-like "zzrrip", shrill lisping "siiir" or "ssssi" note like that of *Tolmomyias sulphurescens*, and longer "weeep weeep wip-wip-wip" with sputtering quality.
Habitat. Upper understorey and middle levels of humid evergreen and semi-deciduous forest, forest borders and adjacent tall second growth; favours shady ravines. Sea-level to 2100 m in Mexico and Costa Rica; 600-1500 m in Panama and Colombia, i.e. above *R. olivaceus*.
Food and Feeding. Diet largely arthropods, including beetles (Coleoptera), homopterans and caterpillars; berries and arillate seeds also eaten. Forages alone, often at edge of mixed-species flocks, especially those led by tanagers (of genera *Chlorothraupis*, *Chlorospingus*) and Black-faced Grosbeaks (*Caryothraustes poliogaster*); also frequents army-ant swarms (Costa Rica). Sits erect and quiet on low perch 1-10 m up, slowly turning head to peer upwards into mid-storey or down into understorey; rapidly darts out moderate distances in upward sally or hover-glean manoeuvres to capture prey from undersides of leaves and twigs, then dropping away to new perch; rarely sallies to air.
Breeding. Mar-Jun in Mexico and Costa Rica. Nest a bulky, pear-shaped structure with downward-projecting entrance spout at side of bottom, made of rootlets, coarse fibres and dead leaves, suspended 1-5-12 m up from tip of thin twig or vine drooping over open space or small forest stream; nest also used by adults as dormitory during all seasons. Clutch: 2-3 eggs; no information on incubation and fledging periods.
Movements. Largely resident; descends to lowlands during Dec-Mar non-breeding season in Mexico.
Status and Conservation. Not globally threatened. Uncommon to fairly common or common throughout range. Probably locally extinct wherever deforestation has been intense, e.g. in lowlands in Panama. Occurs in Río Bravo Conservation and Management Area, Lamanai Archaeological Reserve and Columbia River Forest Reserve, all in Belize, Rancho Naturalista and Tarcol Lodge, in Costa Rica, and Darién National Park, in Panama.
Bibliography. Anon. 187. **Olivaceous Flatbill**

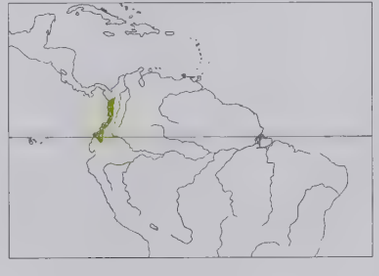
Rhynchocyclus olivaceus

French: Platyrhynque olivâtre **German**: Oliv-Breitschnabeltyrann **Spanish**: Picoplano Oliváceo

Taxonomy. *Platyrhynchos olivaceus* Temminck, 1820, Rio de Janeiro, Brazil.
Geographic variation subtle, and majority of races weakly differentiated. Nine subspecies recognized.
Subspecies and Distribution.
R. o. bardus (Bangs & Barbour, 1922) - E Panama and NW Colombia (N Chocó E to S Bolívar).
R. o. mirus Meyer de Schauensee, 1950 - NW Colombia (lower Atrato Valley and inland from coast).
R. o. flavus (Chapman, 1914) - N & C Colombia (Santa Marta and Magdalena to W Meta) and N Venezuela.
R. o. jelambianus Aveledo & Pérez, 1994 - NE Venezuela (Sucre, N Monagas).
R. o. tamborensis Todd, 1952 - R Lebrija (Santander), in C Colombia.
R. o. aequinoctialis (P. L. Sclater, 1858) - SC & SE Colombia (Meta S to Putumayo and Amazonas) S to NC Bolivia (Cochabamba).
R. o. guianensis McConnell, 1911 - S Venezuela, the Guianas and N Brazil.
R. o. sordidus Todd, 1952 - Brazil S of Amazon (R Tapajós E to R Tocantins and N Maranhão).
R. o. olivaceus (Temminck, 1820) - NC & E Brazil (E Pará; Pernambuco S to Rio de Janeiro).



Descriptive notes. 15 cm; 19-23 g. Large-headed, dark olive flatbill with white eyering surrounding large dark eye. Head and upperparts dark olive, wings dusky, wing-coverts and secondaries edged with ochre, buff or yellow (two dull wingbars), tertials edged yellow; tail dusky with pale outer margins; throat pale grey or pale yellow, breast greyish-olive, belly to vent and flanks pale yellow, breast and flanks flammulated or streaked olive; iris dark; bill very wide and flat, upper mandible black, lower mandible pale horn; legs blue-grey. Sexes similar. Juvenile is duller olive above, paler yellow below, with more ochraceous olive uppertail-coverts. Races differ minimally: *flavus* is slightly larger, longer-tailed, greener above and yellower below than *aequinoctialis*; *jelambianus* has on average wider bill than previous; other races exhibit equally minor morphological differentiation. Voice. Song, mainly at dawn, 5-7 thin, high, nasal, upslurred notes, "tree-tree-tree-tree-e-e-e" or "tuu tee tee ti ti", ascending faster towards end; call a loud, harsh, slightly buzzy "tsheet" or "breeyp" or "pfweet".
Habitat. Mostly lower level of humid forest (especially *terra firme*, also *várzea*) and older second-growth woodland; absent from extremely moist forest on Panama-Colombia border and from black-water and sandy-soil areas of upper R Negro and R Orinoco drainages. Sea-level to 500 m; to 1000 m near Andes.
